There is one set of variations which, unlike all those which have been mentioned above, is to a certain extent under the control of the engineer—I mean the variations on the two sides of a circuit which is arranged upon a three-wire system. Here, of course, the engineer in the first instance endeavours to connect about the same number of lamps wired on each side of his system, and to see that the balance is approximately right, not only over the whole system but over each small section of it. In spite of all the care that may be used in this matter, however, I have found that a three-wire system may be very often greatly out of balance for a few minutes at a time owing to causes entirely beyond the engineer's control. Rapid changes in this respect occur chiefly within the 15 or 20 minutes during which load is coming on most rapidly in the afternoon. In a station when the load was increasing from 2,000 up to 8,000 amperes I have frequently seen that in the course of 10 minutes first the positive and then the negative side would have 400 or 500 amperes more than the other. By the use of a balancing machine, which can be transferred by a single switch from one side to the other, the case, of course, can be met as it arises, but it is sometimes a little surprising that the changes should be so large and so rapid. I have endeavoured to indicate to you some of the great number of variations in conditions in spite of which the engineer has to obtain a uniform result. All these variations, even the last, are practically altogether beyond his control. Some of them occur with considerable regularity and can be foreseen, others are most irregular and come without any warning whatever. But all of them affect very greatly both the method and the cost of production. The method first, because the efficiency and regularity of supply must be considered before the matter of economy. Any method of supply which was inevitably liable to breakdowns and interruptions would be wholly condemned on that ground alone, even if it happened to be of the very highest economy. But given any one of the many methods of supply which are equally good as to result to the consumer, then that method must mainly be judged by its economy under the particular conditions in which it has to work. It will, of course, be borne in mind that the cost of power production in this case is not a mere 3 or 4 per cent., as in the case of a factory. It is 50 or 60 or 70 per cent. of the whole expenses, the balance being expenses of management and distribution, along with interest, depreciation, and other charges connected with capital.

As to the effect, then, of the uncontrollable variations on system or economy, the first thing which I have to point out is that their madness is not entirely without method. There are some points which are as certain as it is that all members of Parliament will not be on one side, in spite of the fact that such a thing is in imagination conceivable! Two of these are of special importance. First of all, there will never be more than certain proportions of all the lamps which are wired alight at once, either at times of maximum or of minimum load. The maximum maximum on the circuit of the Westminster Company is about 35 per cent., on that of the St. James's Company I believe over 60 per cent., of the House-to-House Company about 35 per cent. In Glasgow, where at present the light is solely in the region of offices and shops, the proportion is as high as 56 per cent. You will see that these proportions depend largely upon the nature of the places where the light is used. This proportion, which, of course, can be only an estimate in any particular place until the experiment is made, fixes for the engineer the maximum number of lamps wired for which a given horse-power will supply current. The maximum minimum is an almost equally important quantity, and in most places the engineer has to do with two such maxima, one for the day hours and another for the night. In a purely residential district the night load will always be very small, and the day load will be practically nil. In the City of London the day load, in consequence of the number of dark places to

Digitized by Google

be lit, is considerable, the night load extremely small. In a mixed district like that of the Westminster Company, the day load in the middle of the summer is not greatly more than the night load. It is to be noted, however, that the night load is practically the same all the year round, while the day load, even apart from fogs or exceptional weather, necessarily varies very much. The maximum maximum, also, as we have seen, varies very much at different times during the year, although it never exceeds a certain amount. It is also worth noticing that, in general, the night load on a central station will increase but slowly with the growth of the station. The first consumers who take the light are most often those who are most in need of it, who require it for dark corridors and long hours. Later on, thousands of lamps may come on to a circuit in shops, offices, and in ordinary private houses, without a single one of them being used after midnight. In an average district the day load increases faster than the night load, because out of any large number of shops and offices some are sure to have dark places requiring current in the daytime. But neither night nor day loads increase nearly as fast as the maximum evening load, which—a certain normal condition having once been reached—will increase exactly in proportion to the lamps wired. In an alternating-current station, where very numerous isolated transformers are used, the night load increases nearly proportionately to the day load because of the increase of magnetising current.

The determination of the sizes of units to be used in any station depends essentially on the probable values, absolute and proportionate, of the loads I have mentioned. It is now a commonplace, although a few years since no one seems to have thought of it, that the machinery in a station should be so subdivided that under all sets of conditions which remain steady for a few hours at a time it should be possible to have such machinery as is running, running more or less nearly full loaded—only in this way can much economy be hoped for. It must not be taken, however, that this is a mere question of arithmetic which can readily be settled off-hand. In every case—it is to be hoped—the output of a station will be much greater 10 years hence than it is to-day. The engineer has not uncommonly to consider somewhat difficult *pros* and *cons.* when he is called upon to provide machinery which shall be of such a type that it can allow dividends to be earned during the years of growth and yet remain still suitable in the time of maturity. It is further to be remembered that this question of the choice of size of unit is also quite modified in the cases where condensing plant is used instead of non-condensing. The reasons for this I will not discuss here; I had a good deal to say about them in a recent discussion at the Institution of Civil Engineers. A good condensing engine uses nearly the same steam per indicated horse-power hour at any load above half output. The increased consumption per electrical horse-power hour is therefore proportionately much less than in the case of non-condensing engines, and the economical importance of fully loading the machines is correspondingly minimised in stations where condensing plant is employed. The question of size of unit leads naturally to that of the necessary magnitude of reserve in any case. I think this is a simple matter, but no doubt it is sometimes wrongly treated. To make the reserve a fixed proportion to the total plant, for instance, is a method which can only possibly come right by a fluke. I will not argue for the necessity of a reserve—that appears to me to be beyond any argument. The reserve is required for two purposes—to provide against breakdown of plant and to provide against accidental increase of load on special occasions. It is in the primary conditions of the case that the light absolutely must never go out, even if a machine wholly breaks down at the time of full load. From this it follows as a mere matter of arithmetic that the minimum of reserve must be a unit equal in size to the largest unit in the station, so as to be capable of taking its place if it breaks down. I should have thought that it went without saying that a machine of 100 h.p. could not be a reserve in a station where other machines were of 200 h.p., had it not been that I have seen it often so said. If an engineer considers that the winter, when the full load is liable to come on at any moment, is a suitable time for overhauling his plant, it is obvious that the reserve must be at least double the minimum which I have mentioned. Indeed, most engineers would prefer to have two strings to their bow, and not to know that the breakdown of one machine would absolutely use up the reserve they wanted to keep in case of specially heavy load coming on, as long as it (the breakdown) lasted. This, however, is a question of degree, of caution, and some would say also of nervousness.

Those questions about the running of a lighting station which are essentially matters of mechanical engineering group themselves mainly in three sections, according as they relate to (1) security, (2) efficiency of regulation, and (3) economy of working. It is obvious that the fundamental question of the choice of an electrical system in any particular case connects itself with all three, but this fundamental question I do not propose to discuss here, partly because it is not a matter which can be discussed in a few words, and partly because it is to so very large an extent an electrical matter that it does not fall well within the scope of my present address. Of the three points I have put security first, because no doubt the absolute certainty that nothing short of a boiler explosion, or of the burning down of a station, shall stop the supply of current is really the very first condition of supply. Clearly with any machinery the burning of an armature, the seizing of a bearing, or the breaking of a shaft, are possibilities which may have to be faced at any moment. They seldom occur—very seldom happily—but sooner or later one or other will come about, and the engineer in charge has to be provided with means for preventing any such accident having more than the most transient effect on his light. Of course, the existence of proper reserve plant, such as I have already mentioned, is the first necessity of the case. Scarcely less important, however, is the necessity that such reserve should be almost instantly available. Where all the plant is running in parallel—*i.e.*, where all the dynamos or alternators are working straight through the same pair of omnibus bars on the switchboard—it will very often happen that the other machines which are at work may of themselves be able, at least for a few minutes, to take up the load of the one which has broken down, and so to allow time for another machine to get started. It may quite well happen, however, that these machines may be themselves running very nearly at full load, and that the broken-down machine may have had so large a load upon it that this is impossible. In any case a large machine—say 400 h.p. or more—cannot be started and got on circuit in a few seconds, and seconds are of importance in these cases. For this reason, in stations which use alternating currents it is usual, and probably necessary, to have one reserve machine always warmed up and running round at half speed, so that it is merely a matter of opening a stop-valve to let it away in a condition ready for putting on circuit, although the synchronising in is unfortunately always a matter which may cause some minutes' delay. In continuous-current stations it frequently happens that a battery is used which can give so high a discharge for four or five minutes as to take the place—along with the machines remaining on circuit—of the machine which has given way, until another machine has been started and put on. So far as it goes this is no doubt a great advantage, but it must be remembered that the mere existence of a battery, and even of a battery quite sufficient for helping in day and night light loads, is not sufficient to ensure that the battery shall be available for help in this fashion. Two details are easily seen to be essential when it is remembered that the failure may occur during the hours of full load. As the volts are highest at such a time, the battery must not only have sufficient capacity but also must have a sufficient number of cells to give in discharge the full E.M.F. of the station, and this will not be the case unless the engineer has specially provided for it by an unusually ample number of cells. Secondly, the battery must have been fully charged beforehand so as to have the maximum E.M F. per cell available. This involves that the battery charge should have been completed during the day, before the hour at which full volts could possibly be required from it in case of any accident. A battery which could only discharge heavily at 215 volts would be practically no use whatever as security against a drop of pressure after an accident which might possibly occur at 230 volts.

In an alternating-current station where the machines are not run in parallel, but where each alternator supplies current to its own separate circuit or bunch of circuits, the sudden failure of a machine must instantly cause extinction of light in the circuit affected for the fraction of a minute which must elapse before the circuit can be thrown on to other machines, or the few minutes which it must take to get another engine started and plugged on. In a station worked on this plan, however, the machine which is turning round as stand-by can be kept excited and giving the volts corresponding to its speed, and can be plugged on in readiness, so that the circuit from any machine which has broken down can be instantaneously switched on to it and it can be run up at once to full E M.F. without, of course, any of the delay which would be unavoidable if it had to be synchronised and put in parallel. It has also to be borne in mind that in cases where a number of alternators are running in parallel the breakdown of one may tend directly, in certain cases, to endanger all the others—a trouble which does not exist if circuiting be used. On the other hand, the circuiting system causes inevitable, if slight, flickers in the light, which are quite avoided by running in parallel. It also necessitates the use of comparatively numerous circuits, as no one can be allowed to carry more than from 30 to 50 kilowatts at a time when it is switched on or off. It must be recognised that in one matter the requirements of security and of economy are more or less opposed. If an engineer is quite certain that, whether by the help of batteries or otherwise, he can bring his reserve into action so promptly that the worst breakdown will not spoil his lighting, he will no doubt always run each unit of his plant at nearly as its full capacity as possible. But if for any reason he cannot be so sure of his reserve, he will gain greatly in security by running his plant always so far under its maximum that he can distribute the load of any one unit for a few minutes over the others without endangering them. But, of course, this is practically equivalent to under-rating the whole capacity of the plant by a considerable percentage, probably 20 per cent., and consequently of increasing the capital cost of the plant per unit of normal maximum output by just the same percentage—a result which one does not wish to face.

(To be continued.)

PHYSICAL SOCIETY.

At a meeting of this society on the 13th inst., Prof. A. W. Rücker, F.R.S., president, in the chair, Mr. W. G. Rhodes, M.Sc., was elected a member of the society.

The **President** invited discussion on Prof. Henrici's paper on calculating machines, and said a description of Mr. Sharp's harmonic analyser, giving direct readings of the amplitude and epoch of the various constituents simple of harmonic terms, had been sent in. This machine requires no adjustments to be made before using. The amplitude is given by the length of a line joining the initial and final positions of the point of contact of a roller with a rotating disc, whilst the epoch is determined by the

Digitized by Google

angle which this line makes with the plane of the roller in its initial position. **Prof. Perry** congratulated Prof. Henrici on the success attained with his analysers. Referring to planimeters, he said the average error made in working out indicator diagrams with Hine and Robertson's instrument was only about one-third that made with Amsler's. After pointing out the great importance of Fourier's series to practical men, and especially to electrical engineers, he said that in studying reciprocating motions, such as those of pistons, valve gears, etc., it was most useful to resolve the motion into its fundamental harmonic motion and its overtones. In this way remarkable differences would be seen between various motions which have the same fundamental, and which are usually considered equivalent. In 1892 he had published the numerical work for a given periodic curve developed in Fourier's series, and he now exhibited a graphical solution done by one of his students, who was probably the first to carry out the late Prof Clifford's idea of wrapping the curve round a cylinder and projecting it on different planes. Prof. Henrici had, he said, based the construction of his first analyser on Clifford's method, but used the Henrici principle—viz., $\int y \sin\theta\, d = \int \cos\theta\, d\, y$, when integrated over a complete period—to explain the later machines. As a matter of fact, the first machine in which the coefficients were determined by an Amsler planimeter carried by a reciprocating tangent plane was a beautiful example of the Henrici principle, and he, Prof. Perry, saw far greater possibilities before it. The defects in the first instrument were mechanical ones, and could be got over by increasing the amplitude of the harmonic motion. Not only was the machine useful for Fourier expansions, but by giving suitable motions to the tangent plane developments arbitrary functions in spherical harmonics, Bessel functions, Lawe's functions, and other normal forms could be determined. He had designed a machine which, on Prof Henrici's principle, developes arbitrary functions in Bessel's, and hoped to have shown it in working order at the meeting; the Easter holidays had prevented its being finished in time In this machine the motion is given to the table by a cam and roller, the cam being shaped so that the displacement of the table is $x \times J_1(x)$ when the shaft turns through an angle proportional to x. The revolving cylinder is driven by variable gearing from the cam shaft. By using cams of other shapes, developments in many normal forms may be obtained; the machine is therefore of general analytical use. An example of development in Bessel's worked out arithmetically by two of his students (Messrs. Hunt and Fennel) was given, and the process of performing the integrations by the machine described. **Prof. Boys**, speaking of arithmometers, said Prof. Selling's machine had several inconveniences. In the first place, it occupied a large space, and the projecting racks were apt to upset things put behind the machine. Secondly, the result of any operation was indicated by continuous motion, and therefore cannot be read off instantly with certainty. On the other hand, the Brunsviga was very compact and convenient, the only serious defect being that one cannot carry on figures obtained as the result of one operation to work with again, as was possible with the well-known Colmar machine. As another improvement he suggested that the two sets of numbers on the wheels, showing the result of any operation, should be coloured differently, so that it would be easy to see whether multiplication or division had been performed. The labour of operating with large digits could then be considerably reduced with certainty. For example, in multiplying by 2 9 9 8, instead of 28 (2+9+9+8) turns of the handle, five would be sufficient—viz., three in the forward direction and two backward, thus giving 3 0 0 2. In his opinion logarithm tables were not nearly so convenient for ordinary calculations as this machine **Mr. A. P. Trotter** described how, by the use of templates cut to special shapes, one could obtain true curves from those given by recording voltmeters and similar apparatus. **Mr. Yule** said he had recently seen the newest analyser made by Coradi for Prof. Weber, and was present when it was tested by the latter on a simple harmonic curve. It gave excellent results, the errors not amounting to one part in 2,000. Speaking of the "hatchet" planimeter, he thought the first one was exhibited by Mr. Goodman at the Institution of Civil Engineers. **Mr. A. Sharp** remarked that since last meeting he had designed an inversion of the mechanism in his harmonic analyser which made it much more practical. **Prof. Henrici**, in reply, said the uses of his first machine suggested by Prof. Perry might lead to great developments in this subject. Lord Kelvin had shown that with the sphere and roller integrator products of two functions, such as $f(x)\, F(x)\, d\, n$, could be got. Referring to Prof. Boys's criticism on the Selling arithmometer, he did not consider the difficulty in reading off the results at all serious. Mr. Trotter's method of solving problems by templates might be very useful. Speaking of the "hatchet" planimeter, he said he believed it was first brought out in Denmark. Mr. F. W. Hill, of the City of London School, had sent him a solution of its action. Mr. Sharp had made a very considerable improvement in his machine, and the elements of this integrator may be useful for other purposes.

Mr. P. L. Gray, B.Sc., A.R.C.S., read a paper "**On the Minimum Temperature of Visibility**," describing experiments made to find the lowest temperature at which bright or blackened platinum becomes visible in the dark. The instrument used was a Wilson and Gray's modification of Toly's meldometer, in which a thin strip of platinum, about 10cm. long and 1cm. wide, is heated by an electric current. The expansion of the strip is indicated by an optical method as used for estimating the temperature of the strip. To calibrate the arrangement, small particles of substances having known melting points were placed on the strip and observed through a microscope, the position of the spot of light showing the expansion being noted when the substance melted. The general conclusions arrived at are: (1) that the minimum temperature of visibility is the same for a bright polished surface as for one covered with lampblack, although the intensity of radiation in the two cases may be different; (2) that the visible limit at the red end of the spectrum varies greatly for a normal eye according to its state of preparation—exposure to bright light diminishes the sensitiveness of the eye and darkness increases it; (3) that for the less sensitive condition the minimum temperature of visibility for the surface of a solid is about 470deg. C., but this may be much reduced by even a few minutes in a dark room; (4) that at night a surface at 410deg. C. is visible, and that by resting the eyes in complete darkness this may be reduced to 370deg. nearly; (5) that different people's eyes differ somewhat in their "minimum temperature of visibility," but probably not to any great extent if tested under the same conditions as to preparation, etc. To most observers the strip at these low temperatures had no appearance of red, but looked like a whitish mist. Inserting a plate of glass or a layer of water in the line of vision had no effect on the temperature of visibility. **Mr. Blakesley** enquired if the author had tried condensing the light from the strip. As to colourlessness, he observed that the parts of the retina active in oblique vision were less sensitive to colour than the central portions. **Dr. Burton** remarked that in the experiments the presence of light, and not colour, was being observed. When illumination was faint, as in twilight or moonlight, it was very difficult to distinguish colours. In the solar spectrum one did not see any whitish termination at the red end. **Mr. Elder** said Captain Abney had shown that all colours appear grey when of small intensity. The **President** thought the question as to whether visibility depends on wave length or on energy was an important one. Probably a minimum amount of energy was essential. At such low temperatures the emission curves of the different wave lengths may not have become sufficiently separated to be distinguished. **Mr. Gray**, in reply, said Prof. Langley had shown that a minimum, but very small, amount of energy was necessary to vision in all parts of the spectrum.

Dr. Burton's paper on "The Mechanism of Electrical Conduction," was postponed.

LEGAL INTELLIGENCE.

IVES AND ANOTHER v. WILLANS.

In the Court of Appeal, on Tuesday, judgment was delivered in the case of Ives and another *v.* Willans. This was the plaintiffs' appeal from the judgment of Mr. Justice Kekewich, staying proceedings in the action and referring the matters in dispute to arbitration. The defendant entered into a contract for the construction of the Liverpool Overhead Railway, and let out certain portions of the work under a sub-contract to the plaintiffs. The original contract contained a clause referring all disputes to three engineers, whose decision was to be final, and no action commenced until the decision of the engineers had been given and this clause embodied in the sub contracts. Disputes arose between the plaintiffs and the defendant. An action was commenced, and the defendant applied to have it referred. The plaintiffs, however, contended that the matter could not be referred to the arbitrators inasmuch as the defendant had taken a step in the action by asking for a statement of claim. Further, they attacked the fairness of the arbitrators, and contended that as the whole of the matters could not be referred, no part of it ought to be Mr Justice Kekewich, however, referred the question to the arbitrators, and this decision, from which the plaintiffs appealed, the Court now upheld, dismissing the appeal with costs.

MEUX'S BREWERY COMPANY, LIMITED, v. THE CITY OF LONDON ELECTRIC LIGHTING COMPANY, LIMITED - SHELFER v. SAME.

These actions were decided last week before Mr. Justice Kekewich in the Chancery Division of the High Court of Justice. The first action was brought by the owners of a public-house to restrain the defendants from working their engines and carrying on their works at Bankside in such a manner as, by vibration or otherwise, to cause damage to the public-house (the Waterman's Arms), or to interfere with the business there of a licensed victualler, or otherwise to cause annoyance, nuisance, and danger to the occupiers of the house. It appeared that close to the Waterman's Arms the defendants had an electric lighting station with powerful steam-engines and dynamos at work, and it was said that the working of the machinery was causing serious injury to the structure of the house and producing unpleasant vibration throughout the house to the annoyance of the occupiers and customers. The second action was brought for a similar purpose by the publican in occupation of the house under a lease granted by the plaintiffs in the first action. On behalf of the defendants it was contended that, in the absence of negligence on their part, they were relieved by their statutory powers from liability to an action for nuisance, and, further, on the evidence, that no actionable nuisance had been shown to exist. It was also argued that, as the plaintiffs in the first action were only reversioners, they had no right to sue in respect of a nuisance which was not necessarily permanent, and might be removed before their interest fell into possession.

Mr. Warmington, Q.C., and Mr. Badcock appeared for the plaintiffs in the first action; Mr. Warmington, Q.C., and Mr. Waggett for the plaintiff in the second action; and Mr. Moulton,

Digitized by Google

Q.C., Mr. Renshaw, Q.C., and Mr. W. C. Braithwaite for the defendants in both actions.

Mr. Justice Kekewich, upon the construction of the statutes and provisional order under which the defendants were constituted, were of opinion that they was not thereby relieved from liability to an action for nuisance. His Lordship further held upon the evidence that it had been proved that, by reason of the working of the defendants' engines, injury was caused to the premises in question by vibration and noise, and also, in some degree, structurally. Having regard to the manifest inconvenience which would result to the inhabitants of the district which the defendants supplied with electricity if their works were stopped, his Lordship did not think fit to grant an injunction. The plaintiff lessee was, however, entitled to enquiries as to the damages caused to him as such lessee by vibration, noise, and structural injury, and to the costs of the action, and there must be judgment to that effect. As regarded the other plaintiffs, their action so far as it claimed an injunction must be dismissed with costs, it being clear upon the authorities that, being reversioners, they were not entitled to relief by injunction in a case such as the present. They were, however, entitled to an enquiry as to any damage done to the inheritance, but the costs of such enquiry must be reserved.

EBBSMITH v. DAWSON AND OTHERS.

The hearing of this action, the details of which were published in our last issue, was concluded on the 19th inst. before the Lord Chief Justice and a special jury in the Queen's Bench Division of the High Court of Justice. It will be recollected that the plaintiff, Mr. Joseph Ebbsmith, sued the defendants, who were members of a shareholders' committee of the South Staffordshire Tramway Company, to recover damages for alleged libel contained in a circular issued by them to the shareholders. The words complained of appeared in our last issue. The defendants admitted publication, said the words complained of were not libellous, and did not constitute a libel upon the plaintiff. They also pleaded that the words in their ordinary meaning were true in substance, and said they were privileged.

Sir E. Clarke, Q.C., and Mr. G. Spencer Bower appeared for the plaintiff; and Mr. Murphy, Q.C., Dr. Blake Odgers, and Mr. Hugh Fraser for the defendants.

Mr. Ebbsmith, who on the previous day gave evidence, was further examined by Mr. Bower. He was taken through a long correspondence referring to negotiations between the Electric Construction Corporation, local authorities, and the tramway company in regard to the adoption by the latter of an electric traction system.

While the plaintiff was being examined,

Mr. Murphy said that the jury would not be further troubled with the case. Having heard the statement of Sir E. Clarke, and having seen and heard Mr. Ebbsmith in the witness-box, the defendants desired him to say that, whilst they entirely reserved their rights to comment on the conduct of their own directors and of the plaintiff so long as he was their solicitor, they did not intend to convey that Mr. Ebbsmith's withdrawal from the Corporation or his change of name had anything to do with the determination of the connection with it of Jabez Balfour and Wright, and they expressed regret that the words used in the circular had led to that impression. They accepted the statement of the witness in the box that he had changed his name for family reasons, and that the Electrical Construction Company in no way resembled the other companies with which Mr. Balfour was so notoriously connected. They thought that the tramway company had entered into a contract which they ought not to have entered into, but there was no cause of complaint against plantiff in respect of that. He suggested that a *stet processus* should be entered.

Sir E. Clarke said he was not surprised that his learned friend had felt inclined to take the course he had, which was one entirely satisfactory to Mr. Ebbsmith. If the case had gone on he should have shown that the Electric Construction Corporation was an independent company, and was a strong and sound one. As the defendants had authorised his learned friend to make the statements he had done, Mr. Ebbsmith gladly made an end of the whole case, and was entirely satisfied with the course which had been taken.

The **Lord Chief Justice** said he had no doubt the parties had been wise, and a *stet processus* was entered.

COMPANIES' MEETINGS.

METROPOLITAN ELECTRIC SUPPLY COMPANY, LIMITED.

The seventh ordinary general meeting was held on Monday at Winchester House, Sir John Pender presiding.

The **Chairman**, in moving the adoption of the report and accounts (which were given in our last issue), said that they would have seen from the capital account that the second £50,000 of the debentures authorised in 1892 had all been issued, making a total of £100,000, nearly the whole of which was held by the shareholders. This issue of debentures brought the capital up to £600,000, which had practically been all expended, while the continual increase of new customers and the extension of mains would render it necessary for them to make still further provision for coming capital outlay. Referring to the other side of the capital account, they would find that the expenditure during the year had amounted to £35,072, the greater part of which had gone in mains and in the necessary apparatus and connections for supplying new customers. There had also been some expenditure at the Manchester-square and Sardinia-street stations. In the first of these cases, they had found it necessary to alter and supplement the foundations of the engines and machinery, in order to do away with any possible cause of complaint as to vibration, and these works were also having the effect of materially improving the working of the plant. They had doubtless seen that an action in reference to this question of vibration was in course of being heard. He assured them that the Board were fully alive to its importance, and had left no stone unturned to provide for the interests of the Company being properly and adequately guarded. With regard to the expenditure at Sardinia-street, they had sunk a well at the station, and had put down a pumping engine for the supply of water, and from the experience gained they had no doubt that they would be practically independent of the water company and water rates, and that a very considerable economy would thus be effected in one of their prime necessities. The item of management charges disappeared for the first time from the capital expenditure of the year. In dealing with this matter the Board had considered it right to allocate a small portion—about £700—of the salaries of the engineers' department direct to the more important items of construction, by way of percentage, as representing the work done by that department in the way of supervision and actual expenses. But no apportionment of general management expenses had been made to capital this year, the time having now arrived when, in the opinion of the Board, the whole of such charges should be born by revenue. This led him to the consideration of the revenue account itself, which in one sense had been somewhat disappointing. When in November last they issued a circular referring to the prospects of the Company, the Board were guided by the fact that in each of the three quarters which had then been completed the income from current had shown an increase of nearly 50 per cent. over the corresponding periods of 1892. They had therefore reason to hope that the Christmas quarter, under normal conditions of weather and demand for light, would show a similar increase. Owing, however, to the remarkable absence of fogs, and to the exceptional brightness of the general weather, the increase of revenue over the Christmas quarter of 1892 was only 8 per cent. And this was in spite of the fact that their customers were increasing in numbers in about the same proportion as usual. But all lighting companies had been seriously affected by the past winter, and it was simply repeating what had already been dwelt upon by the chairmen of other kindred companies. In their case they estimated the falling off at about £10,000, which, after allowing for extra cost of production, would have given an extra 1½ per cent. dividend on the capital. The total income from current had been £64,312, being an increase of £13,500 over 1892, which had been earned at an additional works cost of £6,600, which would have been only slightly increased to earn the larger income to which he had just referred. With regard to the item of fuel, the Board took full advantage of the reduced price of coal at the time the contracts were made last year, but the small increase of cost under this head as compared with earnings was not so much due to economy in purchasing as to the fact which the Board had always desired to impress upon shareholders—that increase of output did not involve anything like a proportionate increase of cost. The items remaining for special notice were the general management expenses, which now appeared for the first time as a full charge against revenue, and the depreciation fund. With regard to management, very considerable economies had been in operation since last year, reducing the total by nearly £4,000 from the cost in 1892; and as to depreciation, the Board were of opinion at present that the amount they had advised should be written off—namely, £7,000—with the further £1,000 off preliminary expenses—fairly met the case. The final result, as shown in the net revenue account No. 5, was a net balance (after providing for debenture interest) of £13,548. 19s. 4d. With this they recommend payment of a dividend of 5s. a share, carrying forward £1,073 to next year. They would have liked to recommend a larger dividend, but, under all circumstances, they considered that the progress was very encouraging, and that their business was being established on a firm and satisfactory basis. Their lamp connection was still continuing to increase in very much the same proportion as heretofore. The Board were of opinion that the time had now arrived for the institution of transformer sub-stations in some of the more crowded districts. By the adoption of this system they hoped to effect a considerable saving in the cost of supply. Before saying more he referred to a letter received that morning from one of the shareholders. He said he felt greatly disappointed that in the speech made last year the chairman referred to a dividend of 5 per cent. They would recollect also that that was not in the speech in moving the adoption of the report, but he did say, in answer to a question, that his belief was strong that, looking to the growth of the system, they would in all probability pay a 5 per cent. dividend, and he had shown them that day that but for the fact that one quarter's revenue had fallen off by £10,000, the dividend of 5 per cent. would have been declared. He was pleased to say, however, that in the March quarter of the current year their gross revenue amounted to £24,000; in 1893, for the same period, it amounted to £19,000; for 1892 it amounted to £13,000, while in 1891 it amounted to £10,000. They would therefore see that he was justified in saying that he looked forward with the greatest confidence to a 5 per cent. dividend at the end of this year. There were other prospects connected with the system which they might look forward to, and these were in the direction of the use of electric power. They had got these large buildings erected, and the mains laid down to serve customers, and there was no doubt that some means would be found for employing the enormous waste which existed at the present moment. They had

Digitized by Google

not the power which the gas companies had of storing their electricity in great reservoirs, but if, with scientific progress and development, they could establish some cheap system of supplying electric power in large quantities, it would add enormously to the dividend-paying power of this and kindred companies At the time the Company was formed they thought they would receive at least £1 a light. The average price of the light to day was 8s. 9d. That was one of the difficulties they had had to contend against. Then, again, he thought the time would come soon when the different electric companies would have to meet and consider the question of approaching the Board of Trade with a view of inducing them to alter the restrictions and obstructions imposed upon electric lighting companies, which did not give them fair play. In conclusion, the Chairman moved the adoption of the report and accounts, and the declaration of the dividend recommended.

Lord John Hay, G.C.B., seconded the resolution, which, after some discussion, was carried.

The retiring directors, Lord John Hay, Mr. J. C. Parkinson, and Mr. J. D. Pender, were re-elected, and the auditors, Messrs. Deloitte, Dever, Griffiths, and Co., were reappointed. The proceedings terminated with a vote of thanks to the Chairman and directors.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the week ended April 20 were £2,940.

Worthing.—Dr. C. Kelly reports that the health of the district of Worthing is in a most satisfactory condition.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 22nd inst. amounted to £682.

Kingswood.—The Local Board have signed a cheque for £325. 10s. in settlement of electric lighting up to March 25.

Robey and Co., Limited.—Mr. W. W. Richardson, of Messrs. Doughty, Son, and Richardson, Lincoln, has joined the Board of this Company.

Appointment Open.—As will be seen by our advertisement columns, the Corporation of Sunderland require the services of an electrical engineer.

Ayr.—Mr. R. Hammond has made a survey of the burgh with a view to the introduction of the electric light. Mr. Hammond will submit a report to the Town Council.

Acton.—At a meeting of the Local Board it was announced that Mr. Medhurst was to have completed the agreement for the electric lighting of the district this week.

Church-Lighting.—It has been resolved to spend £2,000 in renovating and improving Marylebone Presbyterian Church. The electric light will be placed in the church.

Blackpool.—For the electric lighting of the Blackpool Tower Messrs. Crossley have laid down five gas-engines. Two are of 160 h.p., one of 60 h.p., and two of 35 h.p.

Sale of Business.—The business of Latimer Clark, Muirhead, and Co. is for sale by private treaty. Particulars may be obtained of Mr. J. Worley, 27, Leadenhall-street, E.C.

Newcastle.—A new block, Eldon-buildings, has now been erected at the north-east corner of Grey-street, Newcastle. The building is lighted by the electric light throughout.

Liverpool.—The business premises of Messrs. Henochsberg and Ellis, tailors and outfitters, Islington, are lighted by electricity. On the top of the cupola there is fixed a powerful electric search-light.

Wrexham.—The Town Council have accepted the offer of the Wrexham Electric Lighting Company to sell their provisional order for the installation of electric lighting in Wrexham and district for £350.

Glasgow.—At a meeting of the City Improvements Trust, Mr. W. F. Anderson moved for a return of lines and rentals between the Corporation and the Telephone Company, Limited. The motion was adopted.

Folkestone.—A public meeting has been held at the Tontine-street Cave, at which a resolution has been passed calling on the Corporation to abandon their electric lighting scheme. The proceedings were not unanimous.

The Leeds Tramways.—It may be well to remind our readers that the time for sending in tenders to the Corporation of Leeds for the working of the tramways throughout the city by horse, steam, cable, electric, or other power expires on May 5.

Canterbury.—The Canterbury Museum, Free Library, and School of Art Committee have accepted the tender of Mr. Philpott relative to the fixing of electric bells at the front door and the gallery. He will fix them and keep them in repair for two years for 30s.

Sunderland.—The Sunderland Shipbuilding Company, Limited, Sunderland, have built a new cargo steamer, 345ft. long, and of 5,400 tons dead-weight, to the order of Messrs. Adam and Co., of Aberdeen, Newcastle, and London. It is intended to fit her with electric light throughout, with cluster lights in the holds for discharging at night.

Bournemouth.—The Town Council have approved of the following plans of the electric supply company: transformer pit in Holdenhurst-road, mains for sub-station in Triangle to corner of St. Michael's-road, and transformer pit in Old Christchurch-road at entrance to Dragon Fly-lane. A plan for a new main from Queen's-road to Branksome Wood-road has been disapproved of.

London Agency.—Messrs. Mavor and Coulson, of Glasgow, inform us that they have appointed Mr. H. T. Barnett, of the London Electrical Goods Agency, St. Margaret's Offices, 53, Victoria-street, London, S.W., as their agent for the London district.

Sale of Plant.—Messrs. Welsby and Rousfield, of 51, Corn-street, Bristol, will sell by auction on May 10 the materials of the industrial section of the late industrial and fine arts exhibition, St. Augustine's Bridge, Bristol. Among these are switchboards and electric wires.

City and South London Railway.—The receipts of the Company for the week ended April 22 were £886, against £851 for the same period last year, or an increase of £35. The total receipts for the first half-year of 1894 show an increase of £44 compared with those for the corresponding period of 1893.

Tenders for St. Pancras.—As notified in our last issue, the Vestry of St. Pancras invite tenders for the buildings to contain the electric lighting plant (engines, dynamos, boilers, etc.) to be carried out at the electric lighting and refuse destructor station, King's-road, Camden Town, N.W. Tenders are to be sent in by the 7th May.

Bath.—At a meeting of the Surveying Committee, on the presentation of a bill amounting to £543. 7s. 6d. for electric lighting, it was reported that there had been 139 failures; in 71 cases they were of an hour's duration or more. A fine of 5s. in respect of 71 cases came to £17. 15s., and that sum deducted from £543. 7s. 6d. left £525. 12s. 6d. for payment. The bill was passed for payment.

Thomas Parker, Limited.—As stated in our note columns last week, this Company has been registered with a capital of £75,000, in £10 shares, the objects being to carry on business as electrical and mechanical engineers, and to generate and supply electric power and light. The signatories are John H. Woodward, Edmund S. G. Rees, Wm. Armistead, Chas. H. Iles, Lawley T. Smith, Mein Wilkie, and Robert Willcock.

Littlehampton.—At a meeting of the Local Board the clerk was instructed to reply to those gentlemen who had written to the Board on the matter of the electric light for the town to the effect that, although the Board do not contemplate supplying the electric light in their district at the present time, they would not oppose the formation of a company for the purpose, subject to the conditions being satisfactory to the Board.

York.—The Lord Mayor of York (Alderman Clayton) and the Electric Light Committee of York have visited Oxford for the purpose of inspecting the system of electric lighting adopted by the Oxford Electric Light Company, Limited. The central station at 45, Broad-street and the sub-distributing station in St. Giles's were visited. The committee also visited the works of the Electric Construction Company, Limited, Wolverhampton.

Great Northern Telegraph Company.—The report of the Great Northern Telegraph Company of Copenhagen states that the total receipts for the year 1893, including the balance brought forward, amounted to £352,974, and the expenses to £77,792, leaving a net profit of £275,182. After placing £83,333 to reserve and renewal fund, the directors recommend a final dividend amounting to £54,166, leaving a balance to be carried forward of £38,154.

A Reflecting Standard.—Messrs. Faraday and Son have brought out a reflecting standard for pictures, etc. The standard, which when extended is 5ft. high, is very light and portable. The reflector is a powerful mirror of six sides, thus overcoming the projected image of the lamp filament. The adjustment, in either vertical or lateral directions, is readily made. The standard is light and portable. The tripod and stem are made of black wrought iron.

Brazilian Submarine Telegraph Company.—The report of the directors for the half-year ended December 31, states that the revenue amounted to £96,261, and the expenses to £24,284. After providing for debenture interest, sinking funds, and income tax, there remains a balance, including £3,533 brought forward, of £61,207. First and second interim dividends, amounting to £39,000, have been paid, and £20,000 transferred to reserve, leaving £2,207 to be carried forward.

Stock Exchange Quotations.—Applications have been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation to the £15C,000 5 per cent. debentures of the Telegraph Construction and Maintenance Company, Limited, in lieu of £150,000 5 per cent. bonds expired January 1, 1894. The committee have ordered the partly paid scrip of £100,000 5 per cent. debenture stock of the City of London Electric Lighting Company to be quoted in the official list.

Progress of Lighting in the City.—We are informed that the revenue of the City of London Electric Lighting Company from public service during the first three months of the year was £3 100, and from private £12,460, a total of £15 560, as against £7,839 in 1893, being an increase of £7,721. The number of 8-c.p. lamps connected on March 31 was 84,634, being an increase during the quarter of 19,293, against 35,275, and an increase of 15,034 at the corresponding period 12 months ago.

Electricity v. Gas.—At the eleventh annual meeting of the Gas Managers of Scotland, Mr. Thomas Wilson, of the Coatbridge Gasworks, expressed the opinion that gasmakers were threatened with opposition from electricity on all sides, and that it was a splendid light, but an expensive one. Gas companies, he thought, had nothing to fear from this source. With the improvements effected, and the appliances at the works, together with the increased uses of gas, it was certain to hold its own.

Digitized by Google

Messrs. Drake and Gorham.—Although this is generally considered a slack time of the year in the trade, at least one firm—Messrs. Drake and Gorham—have a large amount of work in hand, both in the way of country house and town lighting. Baron William von Schröder has placed the lighting of the Rookery in their hands. There will be a steam-engine driving a latest pattern Construction dynamo, to provide current for charging a 100-light D.P. battery. The total number of lamps being installed is 200.

Direct Spanish Telegraph Company.—The directors have passed a resolution with regard to dealing with the £62,000 6 per cent. debenture debt which falls due on May 1 next, which provides for calling up the balance of £1 unpaid on the ordinary shares (£12,931), the issue of debentures for £30,000 having 20 years to run and bearing interest at 4½ per cent. per annum, and realising and taking from the reserve fund the requisite balance, approximately £19,000, and paying off by these means the debentures falling due.

Valencia and Alberique Tramways Company, Limited.—This Company has been registered with a capital of £100,000 in £1 shares. The object is to purchase or otherwise acquire from J. Latorre a concession granted by the Government of the kingdom of Spain for the construction of a system of tramways between the towns of Valencia and Alberique, and to carry on business as omnibus proprietors, carriers, electrical engineers, etc , in Spain and elsewhere. The first signatories are S. de los Valles, T. G. Harvey, J. H. Brodie, A. G. Hammond, A. Hulbert, A. J. Secretan, and A. D. MacLaren.

Underground Mains.—The underground work for the Edinburgh Corporation electric light scheme is now in progress. The Doulton casing, as stated in our last issue, is being used, and about 50 miles of "ways" on this system will be laid. The Sunderland conduits will, we understand, shortly be commenced, and for this work about 10 miles of "ways" of Doulton casing will be provided for the reception of the cables. Some bare copper mains in culverts will be laid both at Edinburgh and Sunderland, and special insulators for the work are being supplied by Messrs. Doulton and Co., of Lambeth.

Hooper's Telegraph and India Rubber Works.—We are informed that the estate of the late Mr. William Hooper has now been taken out of Chancery, and that the telegraph and indiarubber works will in future be carried on by Messrs. Jno. P. Hooper and Basil Gee as managing directors of Hooper's Telegraph and India Rubber Works, Limited, 31, Lombard-street, London, E.C., which has been formed for the purpose of continuing the business of manufacturers of indiarubber telegraph cable and general indiarubber goods, and extending the same for the supply of electric light, telephone, and other cables.

Portsmouth —At the electric lighting station, Gunwharf-road, Portsmouth, last week, Mr. Alderman G. Ellis, chairman of the Electric Lighting Committee of the Town Council, turned on the steam from the boilers which are to work the engines for driving the dynamos. A pressure of 165lb to the square inch was obtained. The Hopkinson low-water alarm was tested at the same time, under the superintendence of the Manchester Steam Users' Association, who are acting for the insurance company. The first light was switched on in the engine room. The Mayoress will shortly switch on the electric light for the borough.

Llandudno.—At a meeting of the Improvement Commissioners, the Board sitting in committee read a letter from Messrs. Bellis and Kingsland forwarding, in accordance with the resolution passed by the Board, a draft of the provisional order which they propose *re* the electric lighting of Llandudno. To meet the wishes of several members of the Board, they had omitted the terms of their first suggestion as to purchase, and in lieu thereof inserted a like purchase clause to that in the Bournemouth order. They also included in the draft order the whole of the Commissioners' district. It was resolved that the proposed order and terms be referred to a committee for consideration and report.

Shirley.—At the last meeting of the Shirley and Freemantle Local Board of Health, it appeared from the minutes that an extraordinary meeting of the Board had been held, at which it was resolved that the clerk (Mr. Harle) should apply to the Board of Trade for a license to enable them to supply the district with electric light, and that the clerk take all the necessary steps to carry out the decision of the meeting. The Clerk explained that he had received a long letter from the Board of Trade, in which they stated that it was advisable that the Board should apply for a provisional order. The matter was referred to committee. Subsequently the Clerk announced that he had received several letters from the Brush Electric Lighting Company.

Royal Agricultural Hall —The Theatres and Music Halls Committee of the London County Council report that Messrs. Crompton and Co., Limited, have made an application to the Council for approval of a system of arc lighting for the Royal Agricultural Hall. The suspension of the lamps is effected by means of the conductors, but these are of ample strength, and the engineer of the Council is of opinion that as arranged there is no risk of short-circuit in this portion of the system. They recommend that the application be granted. Messrs. Gent and Co , of Leicester, have secured the contract for lighting the offices and shops into which the centre of the hall has been divided (over 100 in number), and also the stands and exhibits at the forthcoming shoe and leather fair.

Tenders for Exminster.—As stated in our last issue, the Committee of Visitors of the Devon County Asylum, Exminster, invite samples and prices of the following materials: (1) per mile, tinned and stranded copper wires from $^{3}/_{22}$ S.W.G. to $^{19}/_{14}$ S.W.G., insulated with pure and vulcanised rubbers, the insulation resistance of which shall not be less than 600 megohms per mile; (2) per pound, pure rubber strip vulcanising rubbers, prepared tapes, and indiarubber solution; (3) per 1,000ft., best American whitewood casings and moulded covers, in various sizes, from 1½in. to 4in. in width; (4) per gross, single-light cut-outs, ceiling plates, with wooden cord grips, quick-action make-and-break switches, holders and shade carriers, brackets and shades. Tenders should be sent to Mr. Arthur E. Ward, 9, Bedford-circus, Exeter, clerk to the committee, by May 15.

Worcester.—The Town Council have adopted a report of the Water Committee recommending the acceptance of the tender of the Brush Company to supply and fix two sets of electrical pumping plant, consisting of two motors of 30 b h.p., and two three-throw pumps capable of delivering 10,000 gallons per hour to an elevation of 300ft. through 5,000 yards of 10in. main, at an estimated cost of £1,128; and also to lay a main capable of conveying a current sufficient to drive the motors and light 1,000 lamps *en route* from Castle-street to the waterworks at an estimated outlay of £961. During the past year the Town Council borrowed sums amounting to £24,240 for water supply, electric lighting, and street improvements. During the current year the Council expect to borrow other sums for street improvements, water supply, electric lighting, and sewerage works.

Stafford.—At a meeting of the Stafford Town Council, on the report of the Electric Lighting Committee a long discussion has taken place on a recommendation that the tender of Mr. Lovatt, of Wolverhampton, be accepted for the erection of the buildings for the electric lighting plant. At one committee meeting the tender of Mr. Espley, Stafford, was accepted, though it was £20 more than that of Mr. Lovatt, but at a later meeting that decision was changed and the tender of Mr. Lovatt accepted. An amendment was moved that Mr. Espley's tender should be accepted. The arguments advanced in favour of the amendment were that Mr. Espley was a local man, a large ratepayer in the borough, and a large employer of local labour, and it was contended that that was a sufficient reason for accepting his tender, though it was £20 more than that of Mr. Lovatt's. On the other hand, it was affirmed that it was in the ratepayers' interests to accept the lowest tender. In the end the amendment was defeated by 17 to 13 votes.

Birmingham.—The General Purposes Committee of the City Council report as follows with reference to the Birmingham Electric Light and Power Order, 1894: "With reference to Council minutes referring this order to your committee, they report that the areas over which the company propose to extend their powers are practically the same as those embodied in their application of 1892, and referred to in your committee's reports of December 6, 1892, and July 25, 1893 Area No. 1 commences at the junction of Easy-row and Edmund-street, and proceeds thence along Easy-row, Great Charles-street, Summer-row, Parade, Newhall-hill, Legge-lane, Albion-street, Tenby-street, Tenby-street North, Warstone-lane, Vyse-street, Hylton-street, Great Hampton-street, Constitution-hill, Snow-hill, Steelhouse-lane, Stafford-street, Dale-end, Newton-street, Corporation-street, Old-square, Minories, Bull-street, Colmore-row, Livery-street, and Edmund-street to its junction with Easy-row. Area No. 2 commences at the junction of Easy-row and Broad-street, proceeding along Easy-row, Paradise-street, Pinfold-street, Stephenson-street, Stephenson-place, New-street, Worcester-street, Bell-street, Spiceal-street, Edgbaston-street, Smallbrook-street, Holloway-head, Bath-row, Islington-row, Wheeley's-road, St. James's-road, Charlotte-road, Wellington-road, Bristol-road, Priory-road, Park-road, Somerset-road, Richmond-hill, Brook-road, Westfield-road, Woodbourne-road, along the Harborne Railway to Hagley-road, Hagley-road, Manor-road, Melville-road, Lyttleton-road, Park-road, York-road, Portland-road, Hagley-road, Monument-road, Lady-wood-road and Broad-street to its junction with Easy-row. The draft order, as submitted by the promoters, did not appear to your committee to give sufficient advantage to the public in return for the important concessions sought by the company. They therefore instructed the town clerk to lodge a notice of objection on behalf of the Corporation with the Board of Trade. A copy of this notice having at the same time been sent to the promoters, negotiations took place between them and your committee, with the following result: (1) The authorised maximum price for electric energy to be reduced from 10d. to 8d. per Board of Trade unit, the minimum charge per quarter being reduced from £3. 10s to £3. 6s. 8d.; this to apply to energy supplied under the existing orders of 1889 and 1891, as well as to that to be supplied under the new order. (2) The promoters to be compelled to lay mains in certain streets in each area agreed to by your committee within two years from the confirmation of the order. (3) The clauses of the Board of Trade model order with respect to street boxes, supply of energy to owners and occupiers, and to public lamps, etc., to be inserted. The promoters have agreed to these conditions, and as time was pressing, your committee, in pursuance of the authority given them by the Council, have, subject to the insertion of clauses in the order for carrying out the foregoing arrangements, given the necessary consent to the application."

Barnet.—At a meeting of the Barnet Local Board, a lengthy report by the Electric Lighting Committee was read. The committee stated that they had received a letter from the Brush Electrical Engineering Company giving terms on which they would light the district. A draft agreement was also submitted to be signed by householders agreeing to take for a period of at least three years from the commencement of such supply, an amount of energy not less than 30 units per lamp fixed per annum, and pay

Digitized by Google

for the same at the rate of 6d. per unit. A report had also been received from Messrs. Crompton and Co., Limited, upon the same question, and the committee was advised by the company that the supply of electric light could be successfully undertaken if from 2,000 to 3 000 8-c.p. lamps were fixed in private houses. The price to be 6d. per unit, a price which the Brush Company say "is unquestionably cheaper than the present price (in Barnet) for gas, to say nothing of deterioration of decorations, pictures, books, and tradesmen's stocks." On the other hand, the committee are advised that the installation of the necessary wires and fittings inside a house, the expense of which would have to be met by the owner or occupier, will cost at least 25s. for every point to which the current is taken. The committee remind the ratepayers that electricity is now suitable for cooking and warming as well as for lighting purposes. At an adjourned committee, a draft circular was prepared with the object of asking householders as to whether they were prepared to take the light, and the committee recommended that 500 circulars and 500 agreements be printed and left by the collector at the houses of ratepayers whose assessments exceed £20, and if not returned by May 12 be called for. Attention was called to the fact that if the undertaking is to pay its working expenses, there must be an annual income from private lighting amounting to about £1,100 or £1,200 per annum, after taking credit for £465 as now paid for public lighting. To get this income it is necessary that the undertaking should have 2,000 lamps fixed in private consumers' houses, taking on an average 25 units of electricity per lamp per annum, and paying at 6d. per unit 12s. 6d. per lamp fixed per annum to the undertakers. In conclusion, the committee, after taking all the circumstances into consideration, felt it would not be prudent for them to proceed further until the Board was assured in a manner admitting of no mistake that if the Board undertook the electric light under their provisional order (at an expenditure not far short of £10,000) the necessary income will be forthcoming from private consumers to pay the working expenses of the undertaking as well as interest on capital and sinking fund. The committee also pointed out that on the assumption that the estimates are accurate and the private consumers take the light to the extent mentioned, the income would be sufficient to pay working expenses together with interest at 4½ per cent. to include sinking fund. The committee also recommended that a cheque be drawn for £10 in favour of the Brush Electrical Engineering Company. The report has been adopted, and the circulars and agreements are to be printed and circulated.

PROVISIONAL PATENTS, 1894.

APRIL 16.

7530. **An improvement in electrical glow lamps.** The Edison and Swan United Electric Light Company, Limited, and John Miles Moffat, 28, Southampton-buildings, Chancery-lane, London.

7539. **Improvements in lifting, crane, and hoisting apparatus operated by electrical energy.** George Llewellyn Davies, 55, Chancery-lane, London.

APRIL 17.

7603. **Application of electricity to the manufacture of cyanides and ferrocyanides and improvement in same. Preservation of vessels from corrosion.** Charles James Hammerton, 8, St. John's-terrace, Rosebery-avenue, Clerkenwell, London.

7607. **Improvements in arc lamps.** Wolf Defries and Victor Isidore Feeny, 60, Queen Victoria-street, London.

7617. **Improvements in thermo-electric generators.** Harry Barringer Cox, 46, Lincoln's-inn-fields, London. (Complete specification.)

7645. **Improvements in underground conduits for electric railways.** James Buchanan Brand and Claud Lorraine Franklyn, 37, Chancery-lane, London. (Complete specification.)

APRIL 18.

7684. **Improvements in or in connection with electricity meters.** Wilfrid L. Spence, The Elms, Seymour-grove, Manchester.

7688. **Improvements in or in connection with electricity meters.** George Hookham and Sydney Holmwood Holden, 18, Southampton-buildings, Chancery-lane, London.

7691. **Improvements in the manufacture of carbon rods for electric arc lights.** Charles August Müller, 2, Market-street, Bradford. (Christian Schmelzer, Germany.)

7700. **Improvements in electric light ceiling roses.** Joseph Devonport Finney Andrews, 15, Marsham-street, Westminster.

7711. **An improved arrangement of element board for electro-diagnosis.** William James Bishop, 70, Chancery-lane, London.

7718. **Improvements relating to mains for alternate-current installations.** George Gatton Melhuish Hardingham, 191, Fleet-street, London. (The firm of Felten and Guilleaume, Germany.)

APRIL 19.

7758. **Improvements in induction electrical machines.** Frederick Tudsbury, 15, St. James's-row, Sheffield.

7801. **Improvements in or relating to electrolytical apparatus.** Carl Kellner, 46, Lincoln's-inn-fields, London.

APRIL 20.

7815. **Improved means for effecting the lighting of velocipedes by electricity.** Thomas James Tomlinson, jun., and Oswald Robson, 3, St. Nicholas-buildings, Newcastle-on-Tyne.

7853. **An improvement in the electro-deposition of heavy metals with a base metal alloy.** William Arthur Thoms and William Henry Burgum, 58, Lombard-street, London.

7865. **Improvements in the construction and working of galvanic batteries.** Desmond Gerald Fitz-Gerald and Alfred William Southey, 53, Chancery-lane, London.

7879. **Improvements in and relating to reflectors for electric arc lamps.** Carl Coerper, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

APRIL 21.

7905. **An improved shunt arc lamp.** Robert James Canavan, 27, Tavistock-place, London.

7920. **Improvements in lead-sheath cables.** James Bassnett Atherton, 6, Lord-street, Liverpool.

7933. **Portable apparatus for heating by electricity water, milk, or other liquids contained in cups, jugs, or other vessels, and for making tea and other drinks.** William Corin, 77, Chancery-lane, London.

7935. **Improvements in electric telegraphy.** Kay Oskar Arthur Gulstad, 46, Lincoln's-inn-fields, London.

7950. **Improvements in apparatus for electrolytical purposes.** Herbert Guthrie, 46, Lincoln's-inn-fields, London.

7955. **Improvements relating to electric measuring instruments.** Jocelyn Home Thomson, 124, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1893.

6528. **Dynamo-electric machines, etc.** Statter.

6551. **Electrically treating gaseous bodies, etc.** Hall.

8567. **Electric lamps.** March.

10081. **Electromotors.** Greenhalgh.

11973. **Electrolysis of water.** Siemens Bros. and Co., Limited, and Obach.

14469. **Electric arc lamps.** Richardson

1894.

3045. **Electric insulating compound.** Bäärnhielm and Jernander.

3902. **Applying electromotors to lathe work.** Chamberlain and Hookham.

Digitized by Google

NOTES.

Portsmouth.—The central station is to be set in operation on the 9th inst.

Aunay-sur-Odon.—M. Fauvel has lighted part of this country town electrically.

Thuringia.—Telephonic communication is to be established between Jena and Weimar.

Zipf.—An electric railway is to be constructed between Zipf and the railway station at Redl-Zipf.

Creil.—The Northern Railway Company are about to electrically light the Creil railway station.

Vals-les-Bains.—Work in connection with the electric lighting of the town is progressing actively.

Budapest.—Large extensions of the electric light conductors are being made in the streets here.

Saint-Girons.—Both public and private electric lighting is on the point of being commenced.

Telephony in France.—It is proposed to establish a third telephonic circuit between Paris and Havre.

An Imperial Train.—A new train just completed for the use of the Czar is lighted throughout by electricity.

Electro-Therapeutics.—A service of electro-therapeutics is to be established in Paris at the Saint-Louis Hospital.

Nischni-Novgorod.—The municipal authorities of this Russian commercial town have decided to build three electric tramway lines.

Marseilles.—The local gas company, which also supplies the electric light, is making extensions in the public electric lighting.

Society of Arts.—On Wednesday evening next Colonel Wells will read a paper on "Telegraphs and Trade Routes in Persia."

Basse-Loire.—The Bridges and Roads Department are considering the question of electrically lighting the banks of the Basse-Loire Canal.

Sainte-Ursanne.—At some new works to be established by M. Rollier electromotors will be used, the motive power being obtained from the River Doubs.

Exhibition at Luxembourg.—An exhibition of work is to be held here this year. Electrical machinery and apparatus are to take a prominent position.

Aix-la-Chapelle.—The horse tramway between Aix-la-Chapelle is to be converted into an electrical line. The financial arrangements have been completed.

Schwanenstadt. — Messrs. Siemens and Halske, Messrs. Ganz and Co., and the Oerlikon Works have sent in offers for the electric lighting of this town.

Electric Shot Firing in Mines.—Mr. Atkinson, the Government inspector of mines, believes in shot firing in mines being effected by electrical methods. And so do we.

Chateau d'Œx.—There is under consideration the question of the electric lighting of the town and neighbourhood, and of the installation of the telephone in the valley.

Metallic Circuits.—The National Telephone Company are introducing metallic circuits throughout the Metropolis. And this after the opposition before the Joint Committee on Electric Powers!

Saint-Quentin.—The local gas company is installing the electric light in part of the town. Power is obtained from gas-engines of 70 h.p. Underground cables on the three-wire system are employed.

Fire at Montreal.—A fire occurred on Tuesday in the Royal Electric Works. Twenty-five dynamos were destroyed, and when the conflagration was at its height the immense flywheel of the largest engine burst.

Saint-Clars (Gers).—The Municipal Council has appointed a commission to investigate a scheme, presented by M. A. Laforgue, of that district, for the establishment of an electric light and power station.

Newport Tramways.—We wonder whether the Corporation of Newport, who are advertising for tenders for the working of the local tramways, would consider the advisability of electric traction being introduced.

The Institution.—The next meeting of the Institution of Electrical Engineers will be held on Thursday, the 10th inst. The discussion will be resumed on the paper by Mr. Crompton on "The Cost of Electrical Energy."

Traction in Algiers.—A project has been submitted to the Municipality by M. Delaise, of the Algiers Omnibus Company, for the construction of an electric tramway on the trolley system. The scheme is under consideration.

Exhibition at Derby.—An electrical exhibition is to be opened in the Mechanics' Institute on the 14th inst. Sir Frederick Bramwell has consented to give a lecture in connection with the exhibition in the Guildhall on May 16.

Bill for Exempting Tenant's Machinery from Rating.—The second reading of this Bill stands for Wednesday next, 9th inst., and it is of the greatest importance that a large majority should be obtained in its favour.

Central London Railway.—The Unopposed Bill Committee of the House of Commons have passed the Bill of the Central London Railway, under which an extension of time is granted until 1900, within which to complete this undertaking.

Warasdin.—This town in Croatia is to be lighted by electricity shortly owing to the efforts of the Industrial Society. The neighbouring town of Czáktornya, which is on Hungarian territory, has been lighted electrically for some months past.

Bingen.—The local Chamber of Commerce has petitioned the postal authorities for the construction of a telephone network for all the large towns of the Rhenish district from the Neckar to the Dutch borders, and specially between Coblence and Bingen.

Chalon-sur-Saone.—The Municipality have reported favourably upon a scheme of Messrs. Péletin and Mollard for the construction of an electric tramway between Chalon-sur-Saône and Bourgnef. The line will be 7½ miles in length, and will cost £40,000.

The Institution Conversazione.—The annual conversazione of the Institution of Electrical Engineers will take place on Thursday, the 31st inst., and will be held, as on previous occasions, in the galleries of the Royal Institute of Painters in Water Colours.

Institution of Engineers and Shipbuilders.—The closing business meeting of the session of the North-East Coast Institution of Engineers and Shipbuilders will be held in the physical lecture-hall of the Durham College of Science, Newcastle, on Tuesday next, the 8th inst.

Auchel.—The Municipality of Auchel, Pas-du-Calais, have had before them a proposal from a contractor to undertake the gas lighting of the town. The question has been postponed, the Municipality expressing their preference for the introduction of the electric light if possible.

B.Sc. Degree in Engineering.—The Edinburgh University Court have decided to recognise the day

Digitized by Google

lectures and laboratory courses given by Prof. Andrew Jamieson at the Glasgow and West of Scotland Technical College, as qualifying *pro tanto* for their degree of B.Sc. in engineering.

Long Winded.—The New York *Electrical Engineer*, in its issue of the 18th April, devotes the insignificant number of 26 pages to an illustrated description of the new head-quarters in which the Postal Telegraph Cable Company has now become established. The *Electrical World* disposes of the subject in 16 pages.

Accumulator Traction.—The management of the Grand Berlin Horse Tramway Company have erected an accumulator station at their premises in Waldenser and Wiclef streets, and will experimentally work a line on the accumulator system from Werftstrasse (Moabit) to Hansa-platz, Lützowplatz, and Potsdamerstrasse.

Protection of Users of Artificial Lights.—In the Metropolis many persons are grumbling about the high charges made for gas on the north of the Thames. In France there exists an organisation to promote the interests of users of gas, electricity, and petroleum, and the third congress of this federation will be held at Rheims in June next.

Lighting of Waterloo Bridge.—The London County Council have referred to the Highways Committee a petition from the ratepayers of North Lambeth calling attention to the Act of Parliament passed last session providing for the lighting of Waterloo Bridge by electricity, and praying that the Council will no longer delay carrying out the work.

Personal.—Mr. Reginald H. Drummond, A.M.I.E.E., has been appointed chief electrician in the Madrid station of the Electricity Supply Company for Spain, Limited. Mr. Drummond, who was formerly engaged as assistant electrical engineer at the Bankside station of the City of London Electric Lighting Company, has already commenced his duties in Madrid.

A Roundabout Method.—Our Berlin contemporary *Kuhlow's German Trade Review and Exporter* frequently gives information as to electrical matters in Germany. The joke of the matter is that *Kuhlow's* does not go to the fountain head for its information, but waits until we have abstracted items from the German technical Press and then scissors our abstracts.

Electric Lighting in Calcutta.—The *Indian Engineer* states that "Messrs. Octavius Steel and Co. have secured the contract for fitting up an electric lighting plant for the United Service Club, in competition with the India Rubber Gutta Percha Company, Limited, the Oriental Telephone Company, Limited, Messrs. Kilburn and Co., and Messrs. Siemens Bros. and Co."

Arsenical Telegraph Batteries.—According to a Leipzig paper, a number of Post Office officials at Abterode have fallen ill owing to the telegraph batteries containing arsenical zinc and arsenical vitriol. Prof. Dietrich, of Marburg, confirms this theory, but, on the other hand, there is the fact that the postal authorities always test the quality of the materials supplied to them.

Electric Gambling Devices.—Complaints are sometimes made in the United States that American progress in electricity is not fully acknowledged in other countries. No one, however, is likely to grudge them the honour (?) of introducing electricity into gambling devices, with the object of swindling greenhorns. But that, it appears, is what is now being done in America.

Electricity Running about an Area!—A lady complained to a magistrate a few days ago that an electric battery that someone had placed in the area of her house annoyed her. She was unable to see it, however, but she could hear it working, and the wires went everywhere. If the lady had been able to see it, there might have been another case of assault and battery.

Heilbronn.—The Wurtemburg Portland Cement Works at Lauffen-on-the-Neckar report that their electricity station, which has now been in operation for five years, is making good progress. A larger demand has enabled prices to be lowered. A new turbine has been installed. At the end of 1892 there were supplied 3,743 incandescent lamps, 32 arc lamps, and electromotors of 48·6 h.p.

German Incandescent Lamp Manufacturers.—A conference of incandescent lamp makers has been held in Berlin with the object of raising the price of lamps. It was decided to form a union of European incandescent lamp manufacturers, and to fix the minimum price per lamp at 75 pfennige (or, say, 9d.) to direct consumers and at 65 pfennige (or, say, about 8d.) to middlemen.

Messina.—Mr. Charles M. Cautry, the United States consul at Messina, in an official report states that the local supply of gas is of bad quality and dear in price. It appears to him that there is an opportunity for an electric light company, the people in Italy being willing to adopt the latest and best illuminant. He says the local tramway company, which has about 40 miles of line, would also be open to adopt electricity as a motive power.

The Lundy Island Cable.—The Lundy Island cable has proved so valuable to vessels frequenting the Bristol Channel, that a useful extension has been made whereby the island is now placed in communication with all parts of the mainland both by day and night. The Lundy cable is 18 to 20 miles in length, and forms a part of the coast telegraphic communication scheme for the purpose of summoning lifeboats and assistance to vessels in distress.

Vibration.—It will be seen from our legal columns that Mr. Justice Stirling has granted an injunction for vibration and enquiry as to damages in the action brought against the Metropolitan Electric Supply Company. The injunction has been suspended for three months, with the possibility of an extension of time being granted. In the meantime it is to be hoped that the precautions being taken by the company to overcome vibration will be successful.

Institution of Engineers and Shipbuilders in Scotland.—At the annual general meeting of this institution last week, the awards of medals and premiums for papers read during session 1892-93 were made. A premium of books was awarded to Mr. John Barr for his paper on "Testing Machinery and Electric Level Recording Apparatus." The discussion of the paper by Mr. William Arnot, A.M.I.C.E., on "The Glasgow Corporation Electric Light Supply," was continued and terminated.

Rubber in Madagascar.—A concession has been granted by the Prime Minister and Commander-in-Chief of Madagascar to the Hon. John L. Waller, ex-United States Consul there, measuring in area 15 miles square, in the district of Fort Dauphin, on the south-east coast, and which is conceded to be one of the richest rubber districts in the island. The discovery of rubber in the district is of recent date; the article is said to be of excellent quality, and is found in large quantities throughout the district.

Lighting of the Baltic Canal.—We referred to the work to be done in connection with the electric lighting of this canal in our last issue. Tenders have now been opened for the same. Nine companies sent in tenders. The Esslinger Maschinenfabrik made the lowest at 513,000

Digitized by Google

marks, with an alternate tender of 490,000 marks, or say £25,650 and £24,500. The Schwartzkopff Company, of Berlin, tendered at 553,000 marks, the General Electricity Company at 640,000 marks, and Messrs. Siemens and Halske at 820,000 marks.

The Lyons Exhibition.—In our issue of the 13th ult. we mentioned that among the electric tramways to be shown at this exhibition would be one constructed by the Creusot Works from the designs of M. Lombard-Gerien, and another by the Fives-Lille Company, in which polyphase currents would be employed. Mr. J. Claret, the promoter of the exhibition, has now arranged to construct on the left bank of the Rhone, between the Lafayette Bridge and the Park, an electric tramway, the main features of which resemble the Lineff system.

Laying of New Mains.—The House-to-House Electric Light Company intend to lay mains in Earl's Court-road, between Wetherby-road and Earl's Court-square; the St. James and Pall Mall Company are about to lay a new feeder main from the station in Carnaby-street along Beak-street, Upper and Lower James streets, Golden-square, Brewer-street, Sherwood-street, and Denman-street, and across Shaftesbury-avenue to the distributing mains in the subway there; and the Charing Cross and Strand Electricity Supply Corporation intend to lay mains along Long-acre, Drury-lane, White Hart-street, Eagle place and court, and across Catherine-street and Marquis-court. The London County Council have approved of the carrying out of these works.

Electrical Apparatus for Amateurs.—Under the title of "Electrical Apparatus for Amateurs," Messrs. Ward, Lock, and Bowden, Limited, of Warwick House, Salisbury-square, E.C., have issued a book of 104 pages giving instructions how amateurs in electrical matters may make electrical apparatus for home use. The book, which is edited by Mr. Francis Chilton-Young, is divided into five parts, each of which has been written by a different person. The first—by Mr. G. H. Sayer—deals with "How I made my Telephones"; the second—by Mr. G. Edwinson—with "The Domestic Electric Light"; the third—also by Mr. Edwinson—with "Magneto-Electric Machines"; the fourth—by Mr. C. J. Clarke—with "A Cylindrical Electrical Machine"; and the fifth—by Mr. R. Williams—with "How I Built my First Coil."

Electric Tramway at Lyons.—A new electric tramway between Lyons and Oullins has been opened by the Lyons Omnibus and Tramway Company. At the generating station there are two Bonnet-Spazin boilers of 140 square metres heating surface supplying steam to two Piguet engines. Each of these is of 150 h.p., running at 100 revolutions per minute, and driving a four-pole Thomson-Houston dynamo. The current is transmitted to the motors by overhead conductors. There are at present in use eight cars, each capable of carrying 50 passengers. The old rolling-stock of the company has been employed, and each car is fitted with two Thomson-Houston motors, which in case of need suffice for conveying 100 passengers. The cars are lighted by five incandescent lamps, three inside and one at each end.

Fibre Conduits.—A new type of conduit for under ground cables has been brought out by the Fibre Conduit Company, of New York. The conduit is made of wood fibre treated with an insulating and preserving compound, producing a hard and solid substance. The fibre is made into tubes, which are completely saturated with a treating mixture which has been prepared under the direction of chemists. The finished pipe is in 5ft. lengths, and is uniform in thickness, with smooth surfaces. It is claimed that this tube makes a strong and perfectly tight duct, which can be readily opened at any point to tap the cables; that it can be easily put together; and that when laid underground it is much more durable than iron, being unaffected by either acids or alkalis. It is also claimed not to contract or expand, or to be injured by heat or cold.

Electric Motors in Workshops.—M. L. Baumgardt describes in a recent issue of the *Elektrotechnische Zeitschrift* a new system of applying electric power to motors in workshops. The author takes a given case of two generators. One dynamo, which may be called A, gives current at 50 volts, and the second, B, generates at 100 volts. The two dynamos are connected in series and united by three conductors, on what may be termed a three-wire system. Some of the motors to be driven are arranged across the two outer conductors. By the adoption of this method, which is explained diagrammatically, each motor can run at different speeds, and it is said that on an average a greater output can be obtained from each motor without changing the position of the brushes than that which it has to give when it is running at the smallest number of revolutions.

Electrical Section of the Franklin Institute.—We have received a copy of the *Proceedings* of the Electrical Section of the Franklin Institute, Philadelphia, from January to December, 1893. A portrait is given of Charles A. Coulomb, and the following papers are recorded: "Some Principles that must be observed in order to make a good Closed-Circuit Battery, and a New Portable Dry Cell Described in which these Principles are Applied," by Mr. E. F. Northrup; "The Migration of the Ions," by Prof. George Flowers Stradling—this is a *résumé* of researches by Hittorf and Kohlrausch on the velocity of ions in solutions of varying degrees of density; "The Chloride Electrical Storage Battery," by Mr. Herbert Lloyd, F.C.S.; "Some Interesting Peculiarities of Alternating Arc Lamps," by Mr. Thomas Spencer; "Notes on Recent Developments in Electricity Abroad," by Mr. Carl Hering; "Charles A. Coulomb and His Work," by Prof. Edwin J. Houston; "The Theory and Design of the Closed-Coil Constant-Current Dynamo," by Mr. Henry S. Carhart; and "Thoughts on Cosmical Electricity," by Prof. Elihu Thomson.

Logislation for Patent Agents.—A Select Committee of the House of Commons met on Monday to consider the Patent Agents Bill and the Patent Agents Registration Bill. Mr. T. H. Bolton was appointed chairman, and the committee decided to meet to take evidence on the 8th inst. The Patent Agents Bill seeks to amend the law relating to patent agents, by incorporating such patent agents as may be willing, and by empowering all patent agents, whether they join such corporate body or not, to elect from among themselves a council to keep the roll of patent agents and to be the governing body of the profession. The Patent Agents Registration Bill provides special facilities for the admission of patent agents to membership of the Chartered Institute of Patent Agents, and seeks to protect the public from deception by the unauthorised assumption of the title of patent agent. The promoters of this Bill state that its object is "not to create a monopoly, but to regulate the profession of patent agents in a manner similar to that in which other professions, such as those of solicitors, veterinary surgeons, and dentists are regulated."

The Government and Telephony.—In the House of Commons on Monday Sir J. Ferguson asked the Postmaster-General whether the agreement with the telephone companies had been completed or had made further

Digitized by Google

progress, and what sum he proposed to expend out of loan on telephones in the present year. Mr. Labouchere asked whether the agreement had been under discussion for nearly two years, and whether the fact of its delay was not practically to enable the company to secure a monopoly of the telephone business in towns as against municipalities that were desirous to obtain licenses, and to provide adequate service for their localities. In reply, Mr. A. Morley said the agreement had been under discussion since June, 1892. He did not think that the effect of the negotiations had been to give the companies any further powers than they had before, or to prejudice the action of the municipalities. Considerable progress had been made with the agreement during the last few weeks, and points of difference between the telephone companies and the Post Office had been brought within such narrow compass that he believed the agreement would be laid on the table very shortly. He preferred not to give an estimate of the amount to be spent out of loan until the arrangements with the companies had been completed. No doubt applications had been made by certain municipalities, and they would be considered on their merits.

The Lauffen-Frankfort Transmission Plant.—As mentioned briefly in our last issue, the report of the Testing Committee in connection with the late electrical exhibition at Frankfort-on-the-Maine has been published. The report, in so far as the transmission of electrical energy from Lauffen-on-the-Neckar to Frankfort is concerned, has been prepared by Prof. H. F. Weber. The conclusions are summarised as follows: The transmission was over a distance of 105 miles, alternating current at from 7,500 to 8,500 volts being used for the purpose, and the conductors being bare copper insulated by oil and porcelain insulators. The efficiency of the transmission—that is to say, of the energy delivered by the alternators at Lauffen and that received in the conductors at Frankfort—was 68½ per cent. at the lowest output of the generators, and 75·2 per cent. at the highest performance. Theoretical investigations showed that the influence of capacity in long bare conductors carried in the air for the transmission of alternating currents upon the efficiency of transmission when using a periodicity of between 30 and 50 is so small that it can be regarded in the projection of transmission plants as being quite subordinate. The working with alternating currents at from 7,500 volts to 8,500 volts by the use of oil, porcelain, and air insulated conductors, extending over 60 miles, is as regular and safe as the operation of low-tension alternating currents in short conductors.

The British Association's Oxford Meeting.—We have received an advance copy of the programme for the forthcoming meeting of the British Association at Oxford, which commences on Wednesday, August 8. The first general meeting will be held in the evening of that day, at 8 p.m., when Dr. J. S. Burdon Sanderson, M.A., F.R.S.E., will resign the chair, and the Marquis of Salisbury, K.G., president-elect, will assume the presidency and deliver an address. On Thursday evening, at 8 p.m., a soirée will take place; on Friday, at 8.30 p.m., a discourse will be delivered by Mr. W. H. White, C.B., F.R.S., on "Steam Navigation at High Speeds"; on Monday evening, August 13, at 8.30 p.m., a discourse will be given by Prof. J. Shield Nicholson, M.A., on "Historical Progress and Ideal Socialism"; on the Tuesday, at 8 p.m., a soirée will take place; and on the Wednesday, the concluding general meeting will be held at 2.30 p.m. With regard to the sectional meetings, the president of Section A—Mathematical and Physical Science—is Prof. A. W. Rücker, M.A., F.R.S., and the vice-presidents are Mr. R. E. Baynes, M.A., Prof. R. B. Clifton, M.A., F.R.S., Prof. E. B. Elliott, M.A., F.R.S., and Mr. R. T. Glazebrook, M.A., F.R.S. The president of Section G—Mechanical Science—is Prof. A. B. W. Kennedy, F.R.S., M.I.C.E., and the vice-presidents are Prof. L. F. Vernon Harcourt, M.A., and Mr. Jeremiah Head, M.I.C.E., F.C.S. Prof. H. B. Dixon, M.A., F.R.S., will preside over Section B—Chemistry and Mineralogy.

City and Guilds of London Institute.—The report of the council upon the work of the institute during last year has been issued. At the Central Technical College, formerly called the Central Institute, at Kensington, the medal instituted by Lady Siemens for electrical students in commemoration of the late Sir William Siemens was awarded to Mr. J. R. Dick, B.Sc. At the Technical College, Finsbury, the number of electrical students is still considerably in excess of the number attending either of the other departments. The council state that they "could wish that the students were somewhat more evenly distributed amongst the three departments. The development of electrical industries has been very great during the past 10 or 12 years, and there is no doubt great scope for still further development in the future; there is, however, a distinct danger that this prospect may attract a superfluously large number of youths into electrical industries; moreover, the opportunities for advancement in mechanical and chemical industries are as great and as promising as in the electrical." A special course of evening lectures was delivered at Finsbury on "Secondary Batteries" by Mr. G. H. Robertson, and a special course on central stations for electric lighting was also announced, but owing to the illness of the principal it was found necessary to postpone it until the current session. Among the additions to the equipment of the college is a Mordey alternating dynamo. At the Central Technical College the dynamo-room has been enlarged and rearranged, and the plant of a model electric lighting station added; various voltmeters, ammeters, electromotors, and a dynamo have been added to the apparatus of the electrical department.

Institution Tit Bits.—As an interpolation to his paper last week, Mr. Crompton said, in reference to one of the Newcastle supply companies' cost of fuel, that "the calorific value was in the coal, but that the engineer could not get it out." A nice little shot at the expense of our American friends was given in regard to the conclusion arrived at some years ago in this country, that it is more economical to subdivide the load between smaller engines than to use one or two huge long-stroke, slow-speed engines. In this connection Mr. Crompton said that "after we had done that for two or three years the Americans rediscovered it." Then, again, in regard to Mr. Parker's recent statement that the electrical efficiency of his dynamos on the Liverpool Overhead Railway is 97·7 per cent., Mr. Crompton remarked that the explanation of that extremely high efficiency was "that the instruments were wrong." Concerning the diagram adopted at Chelmsford for the men in charge of the steam-engines to ascertain for themselves at any time at what load-factor they are driving their plant, Mr. Crompton observed that "this brings home to the man in charge of the engines that he is wasting his employer's money." Mr. Raworth, too, was in a happy frame of mind. They had, he said, one prophet in the Institution; that was Mr. Crompton. Some of his prophecies came true, some did not. The speaker had given Mr. Crompton certain tips in times past; some he had taken, others he had not. Mr. Crompton, he remarked, hit out straight; that was very kind of him. If it was a curve, it fetched Kapp; if an

Digitized by Google

alternating curve, it fetched Mordey; if an engine, it fetched Raworth. Major-General Webber was also anxious to have a say, but as Big Ben had already chimed the half-hour he had to reserve his remarks until next Thursday, the 10th inst.; and remember, gentlemen, the chairman observed, we have only two more meetings this session.

The Epstein Company and Woodhouse and Rawson.—A circular has been issued to the creditors and shareholders of Woodhouse and Rawson United, Limited, with reference to raising additional capital for the Epstein Electric Accumulator Company, Limited. The present issue comprises £12,000 7 per cent. mortgage stock at par. This stock, together with a bonus of one fully-paid ordinary share of £1 for every £2 of stock applied for, is offered solely to the shareholders and creditors of Woodhouse and Rawson United, in consideration of the cancellation of the contingent debt of £11,000 owing by the Epstein Company to the former. Mr. Leslie, receiver for the debenture-holders of Woodhouse and Rawson United, has obtained the consent of the Court to the sale of the assets to Mr. Epstein, and now every creditor and shareholder, whose rights the Court was then, and is now, protecting, is entitled to participate in the benefits of the present proposals. The circular issued by Mr. F. R. Bluett, the secretary to the Epstein Company, states that "the directors have, subject to confirmation, completed negotiations that have been in hand for the last few weeks for the working of the United States and Canadian patents. The company owns these patents in addition to those for France, Belgium, Italy, Spain, and other countries, including India and the more important colonies. Mr. Klingelsmith, with whom the agreement has been made, was for several years general agent for the Thomson-Houston Electric Company, whose expert reported very favourably upon the cells some time ago with a view to their adoption. He was recently deputed by some American capitalists to make investigations in Europe with a view to acquiring the best battery that he could secure, and in the result he has signed a contract, subject to confirmation within six weeks by his principals, whereby they take up a sole license in the United States and Canada on terms that will give the Epstein Company one-fourth of all profits made, with a minimum of £4 per ton of lead used—a substantial deposit being paid after ratification. As the American company will commence with a working capital of not less than £20,000, this should produce a considerable income to this company."

Liverpool Overhead Railway Extension.—The Seaforth Sands section of the Liverpool Overhead Railway was formally opened on Monday, having previously been inspected and approved by Major-General Hutchinson and Major Cardew on behalf of the Board of Trade. The directors, railway officials, contractors, and others interested in the undertaking, proceeded along the line by special train from the Pierhead Station. Up to the present time the northern terminus has been the Alexandra Dock Station. The railway was from the first completed for another half-mile, to the point where the extensive carriage sheds and repairing sheds are situate, and the new portion of the line extends from this point for about 500 yards to the Seaforth Sands Station, which is close to the sands, and near the tram terminus at the Rimrose Bridge of the Lancashire and Yorkshire Railway on the Crosby-road. This extension, which has cost about £30,000, has been completed by Messrs. Holme and King, with Messrs. Pearson and Knowles, of Warrington, and the Phœnix Foundry Company, of Derby, as sub-contractors. The engineers have been Sir Douglas Fox and Mr. J. H. Greathead Mr. S. B. Cottrell, the general manager of the company having acted as resident engineer. The total length of the railway from the Herculaneum Dock Station at the south end, to the Seaforth Sands Station at the north end, is a little over six miles, and nearly £600,000 has been expended in its construction and equipment. The next extension of the line will probably to the Seaforth Station of the Lancashire and Yorkshire Railway—about half a mile away—and in the event of such an extension being decided upon, an exchange station will be erected there. At present there are no fewer than 14 stations on the six miles of electric overhead railway, and it is proposed to open three new stations on the existing system—between the Clarence and Sandon Dock Stations, the Sandon and Canada Dock Stations, and the Brocklebank and Alexandra Dock Stations. At a dinner which was given on Monday, the chairman, Sir Wm. Forwood, said that the line was admitted to be the greatest achievement of electrical science of the present day. Therefore he felt that the people of Liverpool had just cause for pride, inasmuch as they were the originators of the first steam railway from Liverpool to Manchester, and now the originators of the first *bonâ fide* electric railway.

Magnetic Property of Discharges of Static Electricity.—An article by Mr. H. Zielinski on the magnetic property of discharges of static electricity appears in the *Elektrotechnische Zeitschrift* of April 26. With regard to the practical application of the magnetic properties of electrical discharges, the author says that it is desirable to possess an apparatus which after each thunderstorm will indicate whether the discharge has passed to earth through the lightning conductor—that is to say, whether the installation of protectors has been damaged and requires rearrangement. He describes various appliances devised for this purpose, but which he considers are not absolutely to be depended upon. The ideal lightning indicator in his opinion is one which under all conditions will only come into operation on an atmospheric discharge, but which will not be influenced by electric currents no matter their strength. An apparatus claimed to fulfil this condition is described. It consists of a circular box provided with a movable glass lid and a metal cover to protect it against damage. Swinging on a steel point is a series of magnet needles, of which a convenient number can be magnetised. In the apparatus described and illustrated the magnet system has the form of a 12-pointed star. The box is suitably fixed to the lightning conductor, and care is to be taken that the suspension point of the needle is such that a galvanic current passing along the conductor will deflect the needle. The glass cover has on its inner surface a mark, and a corresponding mark is arranged on the magnet system. The apparatus is fixed in such a manner that the mark on the glass lid covers the one below. If now an atmospheric discharge passes through the conductor, the magnetism in the needles is destroyed, and new magnetism is produced in the star in the direction of the lines of force of the discharge. Under the influence of the earth's magnetism, or of the lightning conductor itself in case this is of iron, the star magnet will then turn a certain angular distance and remain in the fresh position taken up. The marks which previously covered one another now appear crossed. If at the close of the storm the marks are observed to be crossed, that proves that the lightning conductor has led an atmospheric discharge to earth. In this case it is only necessary to again turn round the glass lid so that the marks cover one another once more, and the apparatus is then ready to indicate another discharge. The apparatus is very sensitive, and is said to be very reliable.

DESTRUCTIVE EFFECTS OF ELECTRICAL CURRENTS ON SUBTERRANEAN METAL PIPES.

This is the title of a lengthy paper which has just been read by Mr. Isaiah H. Farnham before the American Institute of Electrical Engineers. The subject possesses a much greater immediate interest in America than it does here, because of the extensive use there of electrical energy for tramway purposes. It was in 1891 that the author of this paper first attributed to electrolytic action the corrosion which was found upon, or in, some lead-covered telephone cables used in Boston. He says:

"A few months later the lead covering of a cable (No. 208), resting upon the ground in manhole chamber No. 76, at the corner of Berkeley and Newbury streets, was found eaten entirely through at the point of contact with the earth. I then felt certain the cable had been destroyed by the action of the current. With Mr. W. I. Towne, my assistant, I proceeded to prove the theory.

"We took measurements between the cable and the earth, the cable having been repaired and raised from the ground, and found 1·5 to 2 volts difference of potential, the cable being positive to the earth. A barrel of earth was procured from an excavation in the street, a metal plate placed beneath the earth in the barrel, and two short pieces of lead cable placed side by side on top of the earth. The plate in the bottom of the barrel was then connected to the negative side of a storage battery giving four

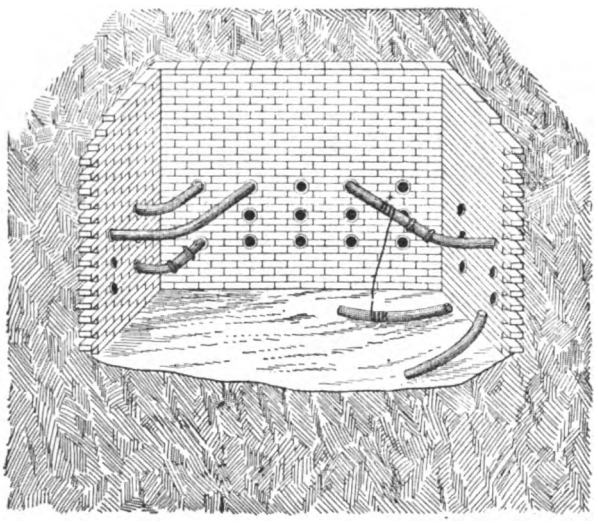

Fig. 1.

volts potential, and one piece of the cable lying on the earth was connected with the positive pole of the storage battery. The second piece of cable in the barrel was left without electrical connections. The earth was then saturated with water, and the circuit was closed, allowing the current to pass from battery to cable, to earth, to plate, and to battery, for seven consecutive days. The pieces of cable were then removed, and the piece which had been connected with the battery was badly pitted, closely resembling the cable which had been destroyed, while the second piece of cable showed no corrosion whatever, proving conclusively that a current such as was found in the manhole was sufficient to cause the damage that had been found, and that the corrosion was not, in the case of the experiment at least, due to any acid or salts in the earth.

"In addition to the experiment just mentioned, we placed in the bottom of manhole chamber No. 76, two short pieces of cable, one of which we connected by a wire to cable No. 208, which had been damaged by electrolysis and subsequently repaired. At the end of six weeks, the pieces of cable were removed and examined. The one which had been connected with cable No. 208 was deeply pitted, while the other piece was free from corrosion." The arrangement of the manhole when this test was made is shown in Fig. 1.

It is all very well, however, to detect corrosion, but proof that the corrosion was due to electrolytic action—and to electrolytic action because of the tramway system—was important; hence a series of measurements was made to obtain the voltage and direction of current, if any, between the cable in the manholes and the earth near the cables. The voltage was found to vary from the cables being negative to earth with a pressure ranging from zero to two volts, the cables being positive to earth to the pressure ranging from zero to 12 volts. These measurements afforded a convincing proof that the electric tramway was the source of the troublesome currents.

The author makes the pertinent remark that "the danger of electrolysis is only where the current is leaving the cable from pipes through the moist earth," therefore it was easy to ascertain what he termed the danger district. Of course, the important problem is to remedy the evil, once having proved it to exist, and the remedies suggested have been many and varied. Of the suggested remedies the author speaks as follows:

"First: It was proposed to remove all cables from the wet bottom and sides of the so-called manholes. It was found very difficult to place and retain cables free from the wet sides, and even could this have been accomplished, the action at the mouth of the ducts and within them would still have continued. They were, however, all removed from the bottom of the manholes.

"Second: It was suggested that the cables might be connected to ground-plates in the manholes, and so transfer the electrolytic action to these plates, and thus save the cables. This experiment was tried on an extended scale, but though many ground-plates having a surface of several square feet each were connected with the cables over a large portion of the city, it was found that voltmeter readings taken between the cables and a point on the earth a short distance removed from the ground-plate in any manhole gave nearly the same pressure as before the ground-plates were connected.

"In some cases the voltage between the cables and the earth was reduced 25 per cent.; in many others no noticeable reduction was made. The ground-plates were

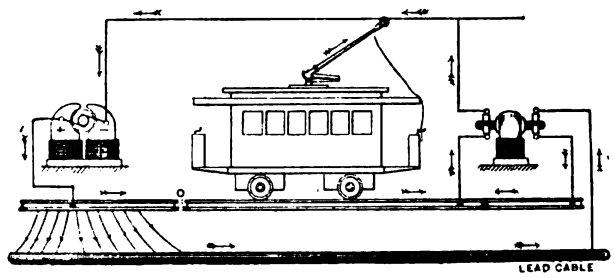

Fig. 2.

constructed from pieces of old lead cable, 6ft. to 10ft. in length, and embedded in the wet earth at the bottom of the manholes. It was evident from this test that ordinary ground-plates would not prove of material advantage for protecting the cables.

"Third: Prof. Elihu Thomson suggested, among other possible remedies, the placing of motor generators at different points along the railway line wherever the cables and pipes are found to be in danger, the motor generators to be operated by the railway power current, the secondary current developed by these generators to be utilised to lower the potential in the cables and pipes to zero with respect to the surrounding earth or rails. The suggestion included means for automatically starting and stopping the generators, as cables might become positive or negative to the rails. The motor generators would, so to speak, pump the current out of the cables and force it into the rails whenever the potential of the former should rise above zero. This plan has not yet been put into operation so far as I am aware. [Fig. 2 illustrates this suggestion.]

"Fourth: Insulating the cables and pipes from the earth was proposed. As some of the worst cases of corrosion of cables by electrolysis occurred where they were painted with asphalte, taped, painted again, and finally covered with a heavy braiding also saturated with asphalte, it was apparent that to insulate cables sufficiently to protect them would be difficult and expensive, if, indeed, practically

Digitized by Google

possible. To protect water and gas pipes by a sufficient insulating jacket was seen at once to be impracticable.

"Fifth: Breaking the metallic continuity of the cable sheath and pipes was proposed. From the fact that severe action is frequently found in comparatively isolated spots where cables and pipes cross each other or pass near or across the rails, it follows that any system of breaking the metallic continuity would have to be studied with reference to the entire complicated system of pipes, cables, and rails ramifying through the streets of a city. There would also be a difference of potential between the several sections of cable or pipe, severed metallically, tending to cause electrolysis at one end of each section, as illustrated in Fig. 3. In case of water-pipes treated in this manner, the action might be expected on the interior as well as on the exterior.

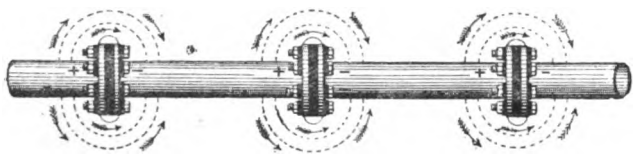

FIG. 3.

"There appears to be some evidence of such an action as this in gas and water pipes where the electrical continuity is partially broken by leaded joints. The action is most severe at points immediately on either side of the coupling. The reason the corrosion appears on both sides of the coupling in this case is not clear; it may be due to reversal of current on the railway system.

"Sixth: My assistant, Mr. Towne, suggested that the railway current might be so frequently alternated as possibly to prevent serious action on the pipes and cables. The theory was that before the oxygen gas liberated by the current should have time to attack the metal the reversal of the current would disperse it. [This plan was soon discarded.]

"Seventh: At about this stage in the study of the problem, Mr. Fred. S. Pearson, then engineer of the West End Street Railway Company, made two suggestions which, though separate in themselves, and presented at different dates, yet carried out in conjunction, have proved exceedingly helpful in overcoming the difficulty, at least, so far as relates to telephone cables. It occurred to Mr. Pearson first, that if the railway current should be reversed so that the positive pole would be connected with the trolley, the danger of electrolysis would be removed from the greater and more scattered portion of the city, and be brought near the power stations, where it possibly could be more easily dealt with. This reversal was made,

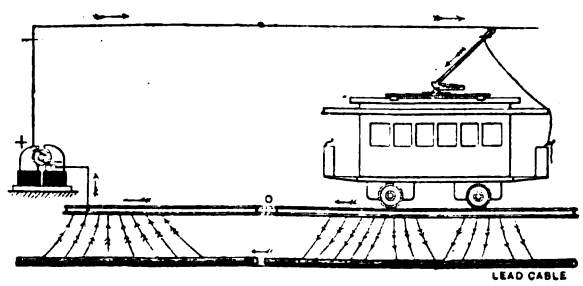

FIG. 4.

and the expected potential changes between cables and earth followed. The safe and unsafe areas were now reversed, the only variation being that by the reversal the neutral or zero line was thrown out a little further from the power-house than it was before. It was also noted that the cables near the power-house which had been from one to two volts negative to earth before the change of current, were now one to nine volts positive to earth—that is, they were raised higher above zero than they had been below zero prior to the reversal. Fig. 4 is a typical representation of the current flowing through trolley, car, rails, and cables at this time.

"Mr. Pearson next suggested the plan of running out large copper conductors from the negative side of the dynamo and extending them through the dangerous district, connecting them at frequent intervals to the cables. Fig. 5 diagrammatically illustrates this plan. On the principle involved in Prof. Thomson's motor generators, this low-resistance conductor connected directly to the dynamo was to pump the current from the cables, and so prevent its passage into or through the moist earth. Some of us were sceptical as to the completeness of this proposed remedy. It seemed possible that even with such a good return conductor, some of the current might still pass into and through the earth. Voltage measurements, however, at once dispelled the doubts, for we found that the cables measuring nine volts positive to earth gave a reading of 22 positive to the return conductor—that is, the return wire, as relating to the cables, was at all points more negative than the earth—if we may be allowed the expression. The return conductors were made up of a large number of No. 18 copper wires formed into cables about 1in. in diameter, known as conductors of 500,000 circular mils. These conductors were extended in each direction from Albany-street power-house entirely through this dangerous district, its longest section being about 5,300ft. The cables in every manhole within the district were connected by several No. 12 copper wires to the return conductor and soldered. On first connecting the cables to the return conductor, which took place December 24, 1892, the current was sufficient to melt several strands of No. 12 wire. A measurement for current flowing in the main return conductor, which was used for relieving the cables only, gave about 500 amperes.

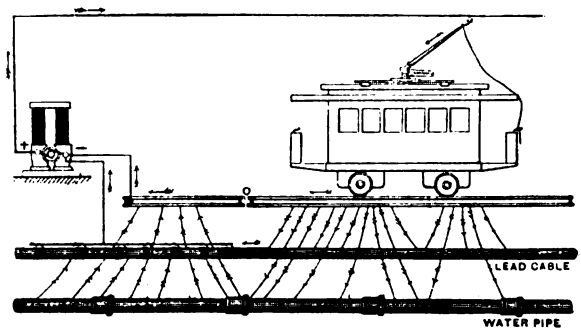

FIG. 5.

"The cables are all negative to earth. The remaining dangerous sections were corrected by taking similar means of reaching the power-house. In treating this latter case, many measurements were made to determine whether or not the railway return wires put up to take the current in a measure from the tracks would answer for a return for the cables, instead of using a special return conductor, as has been employed at the Albany-street district. It was found that they would not answer, since the potential of these track return wires varied constantly and was frequently above that of the earth.

"The cables on the Boston side of the draw of West Boston Bridge, proved to be positive to both the rail and the water, while on the other side of the narrow draw the opposite condition existed, showing at once that it was unsafe to assume any neutral lines or potential difference, without making measurements to determine the absolute facts.

"So far, this paper has dealt particularly with the subject of protection of lead-covered cables. It might be inferred that water and gas pipes can be treated in precisely the same manner with the same results, or as water-pipes have a much greater sectional area of metal, it might be presumed that simply a connection of such pipes to the dynamo at the power station would be sufficient to bring their potential down to zero throughout the dangerous district. The facts so far coming to our notice would materially modify such inferences, and therefore should find a place here.

"That iron pipes are as truly subjected to the corrosion as lead need not be stated to the members of this society, but for the benefit of city officials and others who may read the paper it should be plainly stated that they are quite as readily destroyed by electrolysis.

Digitized by Google

"Mr. Benzenberg writes that the trouble in Milwaukee was chiefly noticed upon the 6in. water-main extending 100ft. on each side of a point opposite the railway power station. Services entering this main were also destroyed, and all were renewed three times during the past two years. He states further, and I quote his own words, 'at other points where power-houses were established thereafter, the mains were immediately connected by extra heavy copper wires with the generator; we have had no trouble with them so far.'"

Other interesting information, principally about water-pipes, was given, and the author concluded his paper as follows:

"When all cables and pipes in the danger district are connected by sufficiently large conductors to drain them, a careful adjustment in resistances in these several conductors may be found necessary in order to ensure a balance between the several systems of pipes. It may lead to the necessity of reducing the carrying capacity of the conductor returning to the dynamo from the rails themselves.

"The question has already arisen, and it doubtless will be repeated here, 'How small a difference of potential between pipe and earth will cause electrolytic action?' In reply to this, it may be stated that some of the worst cases of corrosion in Boston have occurred where the difference was but $1\frac{1}{2}$ volts. Mr. A. T. Wells, of Chicago, in describing to me an examination of some of the first cases in Cincinnati, states that the 'difference of potential between the cables and the rail was never more than one-half and usually less than one-quarter volt.' Such a difference between cable and rail would mean a much less difference between cable and earth where electrolysis takes place. Mr. John C. Lee, of Boston, has experimentally caused the corrosion on lead and iron by a difference of potential of $\frac{1}{100}$ volt.

"These facts certainly indicate that but a very small pressure is necessary to produce the action, and should dispel the numerous statements that well-bonded rails or a large amount of rail return wires will alone overcome the trouble. In some cities where electrolysis is in progress to-day, the return copper nearly equals that of the trolley feed-wire system. We cannot force the current to take one path exclusively when others are open to it.

"The facts given above, with others similar, though not enumerated, lead me to these conclusions:

"1. All single-trolley railways employing the rails as a portion of the circuit cause electrolytic action, and consequent corrosion of pipes, in their immediate vicinity unless special provision is made to prevent it.

"2. A fraction of a volt difference of potential between pipes and the damp earth surrounding them, is sufficient to induce the action.

"3. Bonding of rails, or providing a metallic return conductor equal in section area and conductivity to the outgoing wires, is insufficient to wholly prevent damage to pipes.

"4. Insulating pipes sufficiently to prevent the trouble is impracticable.

"5. Breaking the metallic continuity of pipes at sufficiently frequent intervals is impracticable.

"6. It is advisable to connect the positive pole of the dynamo to the trolley lines.

"7. A large conductor extending from the grounded side of the dynamo, entirely through the danger territory, and connected at every few hundred feet to such pipes as are in danger, will usually ensure their protection.

"8. It is better to use a separate conductor for each set of pipes to be protected.

"9. Connection only at the power station to water or gas pipes will not ensure their safety.

"10. Connection between the pipes and rail, or rail return wires, outside of the danger district should be carefully avoided.

"11. Frequent voltage measurements between pipes and earth should be obtained, and such changes in return conductors made as the measurements indicate.

"In closing this somewhat rambling paper, I can do no better than use words which will remind you of Patrick Henry: 'eternal vigilance' will be the 'price' of pipes and cables where conditions favourable to electrolysis exist."

THE TRANSFORMATION OF DIRECT INTO ALTERNATING CURRENTS AND VICE VERSA.

In a recent issue of *L'Electricien* (April 21), M. Aliamet describes the system devised by MM. Hutin and Leblanc for the transformation of direct current into single or multiphase alternating currents. Fig. 1 gives a view of

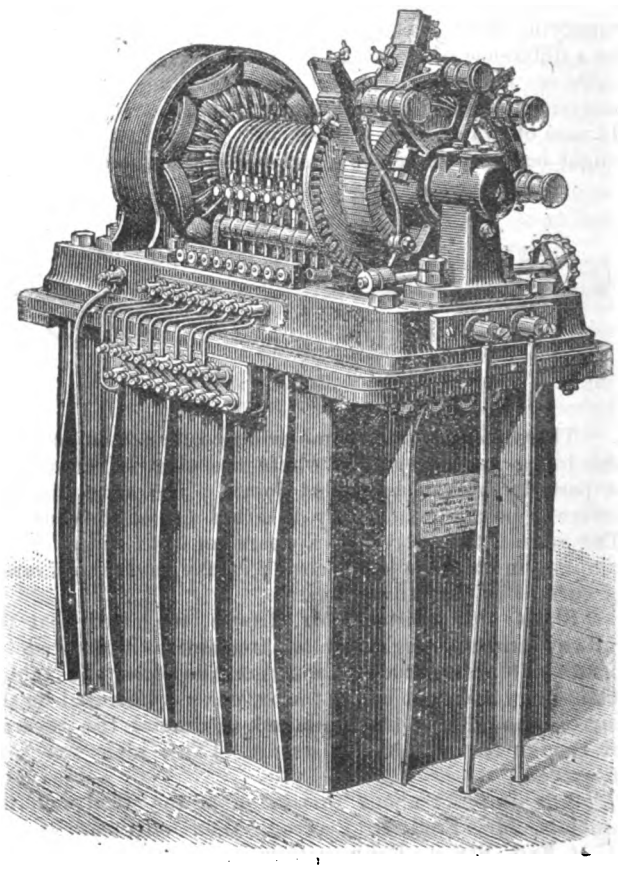

FIG. 1.

the apparatus used. A special type of alternating-current transformer is arranged in the lower part of the standard; above this is a second transformer, which is rotary and reversible, and it comprises a Gramme ring revolving in an eight-pole inductor. In addition to the usual commutator, the shaft has arranged on it a series of bronze rings insulated and provided with brushes; the latter are connected to the terminals of the coils of the primary circuit of the alternating-current transformer by means of connections shown at the top of the standard. The rings are, moreover, connected one by one to the segments of the commutator. The object of the rotary part is to change alternating currents to continuous of the same pressure, and inversely; whilst the lower transformer increases or reduces the voltage. A complete

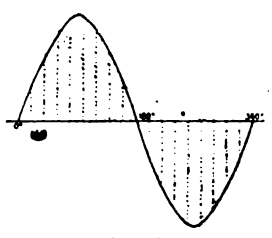

FIG. 2.

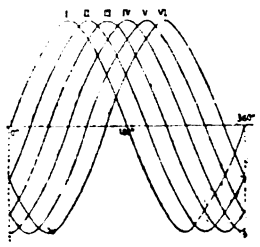

FIG. 3.

installation requires two identical apparatus: the first is the transmitter, and the second the receiver. As the principle of the revolving transformer lies in the properties of the Gramme winding, we will refer to those which more directly concern us.

Let us consider a direct-current machine with a Gramme ring, divided into an equal number, N, of sections, and moving in a uniform magnetic field at a constant speed. It is known that under these circumstances any coil occupies

Digitized by Google

the angle $\frac{2\pi}{N}$, and that it is the seat of a sinusoidal E.M.F. of which the ordinates in Fig. 2 represent on a given scale the successive values in the duration of a period. But each section develops an E.M.F. simultaneously; all have the same amplitude and the same period, and any one differs only from its neighbours by a value $= \frac{2\pi}{N}$. If we suppose N = 6, Fig. 3 shows the E.M.F.'s displacement. By the fact of their arrangement in series, their resultant

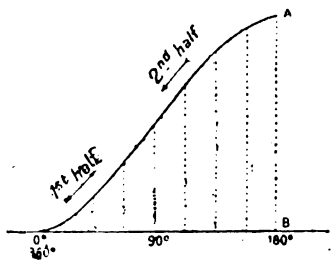

FIG. 4.

is found to be that indicated in Fig. 4. In the latter the E.M.F.'s are deemed rectified, and the successive ordinates are obtained by the integration of those in Fig. 2. The two halves of the ring, divided into two parts by the line of commutation, produce the same resultant; the second is superposed to the first, and arranged, consequently, in opposition to it. When we desire to collect the current, the brushes are placed in O and A, which give the maximum difference of potential. It is easy to see that the ordinate, AB, has not a rigorously

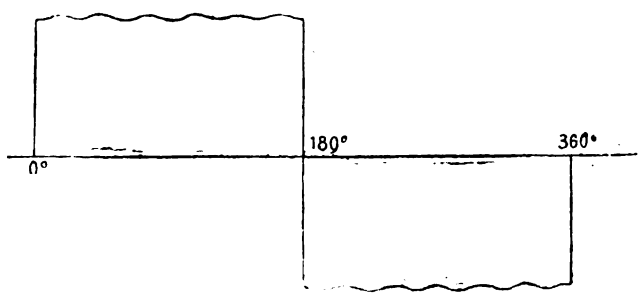

FIG. 5.

constant length. In fact, there is produced an undulation in the value of the resultant E.M.F., and it is found to be all the more marked as the number, N, is smaller. The current naturally presents corresponding variations, but the self-induction of the ring weakens them; they are, moreover, made to sensibly disappear by increasing the section of the coils.

According to the method of utilising partial E.M.F.'s, we can obtain from the Gramme winding a series of different currents. In the ordinary case, the current is continuous in the external circuit and simple alternating in the ring, as represented in Fig. 5, and if the circuit is opened no

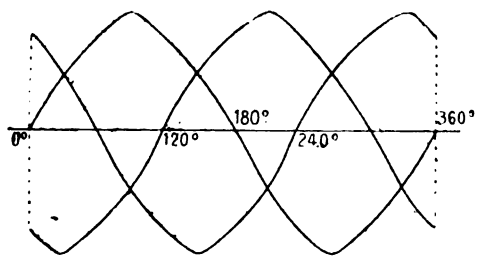

FIG. 6.

current is produced. If we now place on the shaft a certain number of insulated metallic rings (for instance, three) connected to these sections situated 120deg. from each other, we shall obtain in this case triphase currents which will circulate both in the ring and in the three-wire circuit, as in Fig. 6.

To resume, a Gramme ring provided with its collector and a system of rings can give as a generator either simple or polyphase alternating currents or direct current, or both together. These same currents brought to the ring properly will cause it to run as a motor. By furnishing direct current to the brushes of the transmitting appliance it will produce alternating currents, which will be conveyed to the receiving transformer by connecting the two apparatus with as many line wires as there are rings to one of them. The receiving transformer, revolving under their action, will give in the circuit of the brushes a continuous current. In order that the running may be effected without sparking, there must be absolute synchronism between the N E.M.F.'s developed in the transmitter and the corresponding counter E.M.F.'s produced in the receiving transformer.

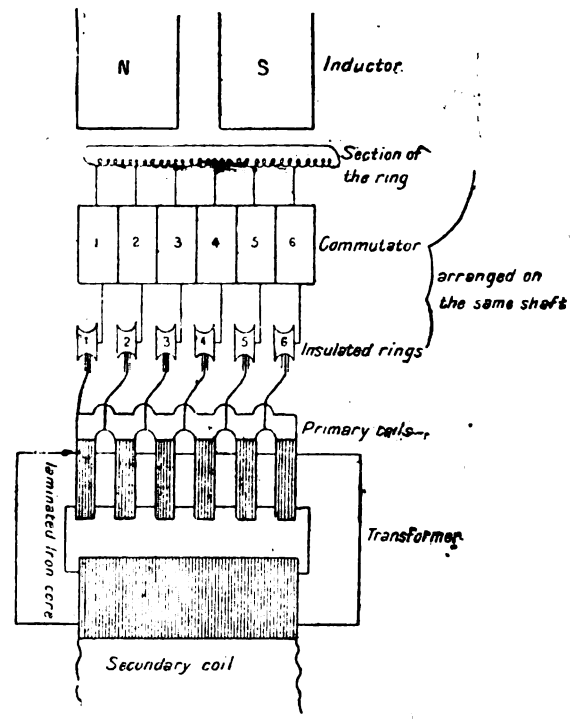

FIG. 7.

The rotary transformer devised by MM. Hutin and Leblanc is represented diagrammatically in Fig. 7. The sections of the ring are arranged in shunt with the primary coils by means of insulated rings and brushes. As it is mainly in the primary circuit that the currents rendered into alternating by the rotation of the commutator should circulate, the ring is of small dimensions because it must only overcome the friction of the brushes. The rings and

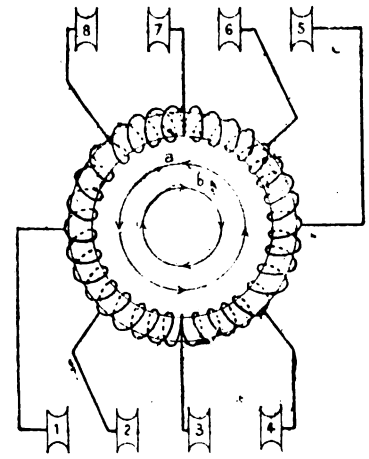

FIG. 8.

the commutator are made rather large to carry all the current. In fact, the latter is distributed between the ring and the primary coils proportionately to the apparent resistances of these two circuits. Thus the transmitting ring revolves as a direct-current motor, but the receiving apparatus works as an alternating-current motor.

The pressure transformer consists in principle of an ordinary transformer with a closed magnetic circuit. The

Digitized by Google

primary is formed of fixed coils connected in shunt with the sections of the ring already mentioned, Fig. 7. All the coils are arranged in series and constitute a closed circuit; the first half is wound in one direction and the remainder is wound in the opposite direction. Fig. 8 shows the primary formed in this manner. This precaution has been necessary for the following reason: if the winding was arranged in the same direction from one end to the other, we should have generally an immovable Gramme ring traversed by a current passing successively through all the groups and the two opposed sections. The result

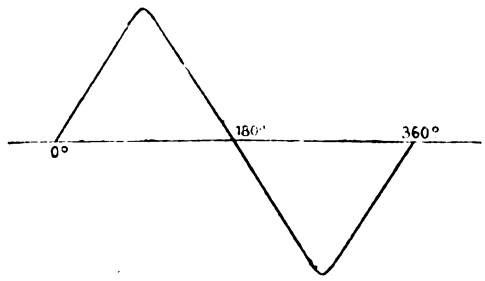

FIG. 9.

would be that the flux would always be in the same sense, and no induction would be obtained in the secondary, *a*. By opposing one half of the coils to the other, the flux passes through the iron in one direction, *a*, during a half period, and in the opposite direction during the following half, *b*. Thus the production of the secondary E.M.F. is assured. The curve given in Fig. 9 shows the variations, the number of turns of each primary section being the same, and the feeding alternating current having the form shown in Fig. 5.

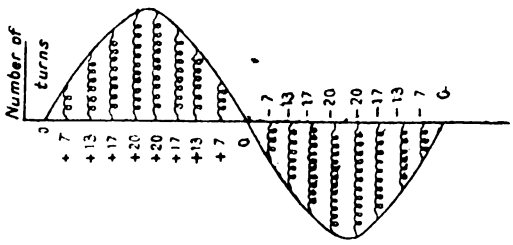

FIG. 10.

In view of other applications, MM. Hutin and Leblanc made the primary of their experimental transformer with coils in which the number of turns varies from one section to another, following a sinusoidal function of time. The ordinates given in Fig. 10 represent by their length the number of relative turns. It is, moreover, evident that with the necessity of getting enough ampere-turns to create a sufficient flux in the secondary, we shall be able to increase the number of turns in the elementary coils in a

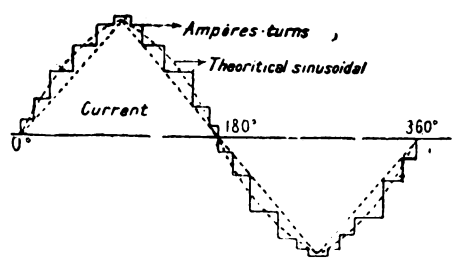

FIG. 11.

given ratio. The object of this special winding is to be able to feed the primary, not solely with an alternating current from a Gramme ring, but also with that of an ordinary type of alternator. It was then necessary to make the curve approximately sinusoidal, Fig. 11.

Let us now examine why only two or three conductors need be used for the line, no matter what is the number of sections of the ring. If there is only one magnetic circuit, the secondary current will be a simple alternating current, and only two wires will be necessary. If, however, it is desired to produce triphase currents the magnetic circuit must have three cores. The three primaries will be identical, but connected, as shown in Fig. 12. The flux is thus displaced 120deg., or a third of a period, and the three secondaries connected so as to produce the arrangement represented in Fig. 13, will give triphase currents which these wires will suffice to convey to the receiving transformer.

We have already seen that the rotary transformer moves according to the alternating current traversing it; if the latter was single-phase, we should be compelled to start the ring by hand, and once in operation it would be liable to stop. Thus, in order to ensure certainty of working, recourse must be had to the use of polyphase currents. By the use of triphase currents sent along the line, the low-tension circuit of the receiving transformer also furnishes three-phase alternating current at the receiving ring. The latter is then in a position to start, and will maintain its speed

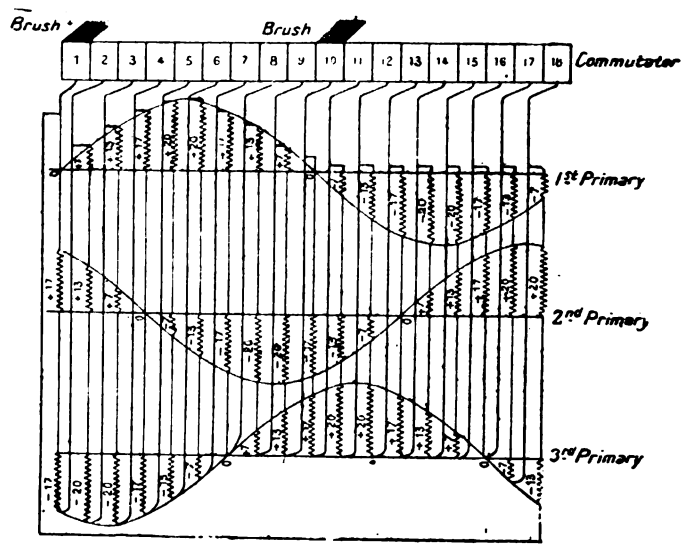

FIG. 12.

without being subject to stoppages. The commutator of the receiving transformer rectifies a single alternating current as well as a multiphase current.

The condition of synchronism being absolutely necessary, the inventors have not been content with an approximation given by the mechanism of the revolving field. To completely avoid sparking at the brushes of the commutator of the transmitting transformer and of the receiving transformer, a synchronising apparatus, arranged on the pole-pieces as in Fig. 14, is used. It will be seen that holes are drilled through the sheets forming the magnetic circuit of the field. These holes are fitted with light insulating material, and copper rods are passed through them. The ends, which are placed on the same side, are riveted to bronze frames which maintain the sheets, Fig. 14A, in such a manner that the "electros" are furnished with a closed circuit of little resistance. The copper rods are as numerous as possible.

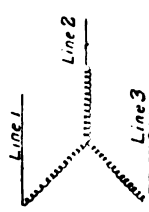

FIG. 13.

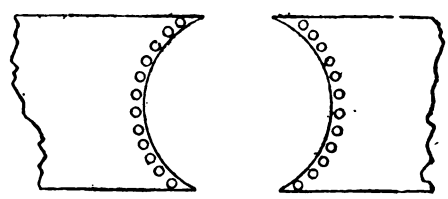

FIG. 14.

To facilitate the comprehension of the working of this method let us consider a Gramme ring revolving in a magnetic field of fixed position; the feeding currents are triphase and brought by three rings, as represented in Fig. 15. Suppose the ring is at work: the resultant field produced by the three-phase currents is A B. This bearing turns round the centre, *o*, in the direction of the arrow, F, for instance, and at a speed equal to the frequency, Ω. We will let the rotary movement of the ring be accomplished; it will be inverse to the direction, F, and its speed yet equal to Ω (when there is synchronism). But the ring takes with it the productive circuits of the rotary field in

Digitized by Google

such a manner that the direction, A B, induced by two inverse and equal movements (Ω and $-\Omega$) remains motionless in the space, making a determined angle, α, with the direction of the inductive field. As the moderating circuit results in a ring winding put in short-circuit, it will be easily conceived that the tendencies to oscillate from A B are completely and instantly overcome by the reaction of the intense currents that its displacement creates in this moderating circuit. In reality everything takes place as if the field, A B, had to be displaced in a very viscous medium. This explanation rests upon the admitted hypothesis that the ring revolves in the inverse

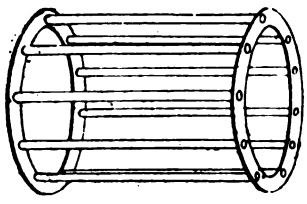

FIG. 14A.

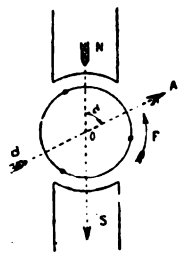

FIG. 15.

direction to the field, A B. We shall see that, if this movement was in the same direction, we could not have a motive couple. In effect, in order that relative displacement between an induced field and an inductive field may take place, it is necessary that their bearings should constantly tend to superpose without ever actually doing so. In a direct-current motor even the play of the commutator counteracts perpetually this tendency in motors with a revolving field; the armature, which always has to overcome at least its own passive resistances, can never revolve as quickly as the inductive field. Finally, in the motor under consideration and which has an inductive field of constant direction, it is the immobility of the resultant, A B, which maintains the desired angular movement.

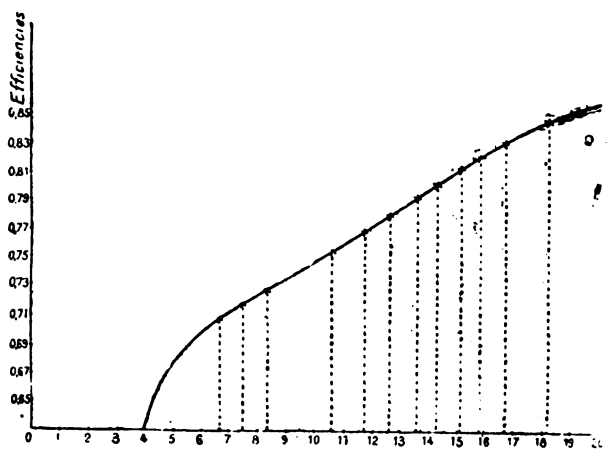

FIG. 17.

The action of this apparatus is such that it is possible to pass, roughly, from no load to full load without the production of sparking. If desynchronisation could take place, the brushes would be immediately melted. In order that the running may be good, a synchronising apparatus must be placed both in the transmitting and receiving transformer. The brushes are automatically placed, and in reality they are fixed once and for all.

It will be seen from Fig. 16 that the motor has eight poles; the commutator is, therefore, quadruple, and, as there are 18 sections, it has 72 segments. It was desired to have a comparatively low speed of 1,200 revolutions, and at the same time to get a reasonably high frequency of 80 periods per second. This has necessitated the adoption of the multipolar type, and it is evident that by changing the proportions of the different pieces a good result could be also obtained with a two-pole type. In Fig. 16 a complete diagram of the apparatus is given, but the motor is assumed to be bipolar so as not to show a lot of connections unnecessary for the purpose of comprehension.

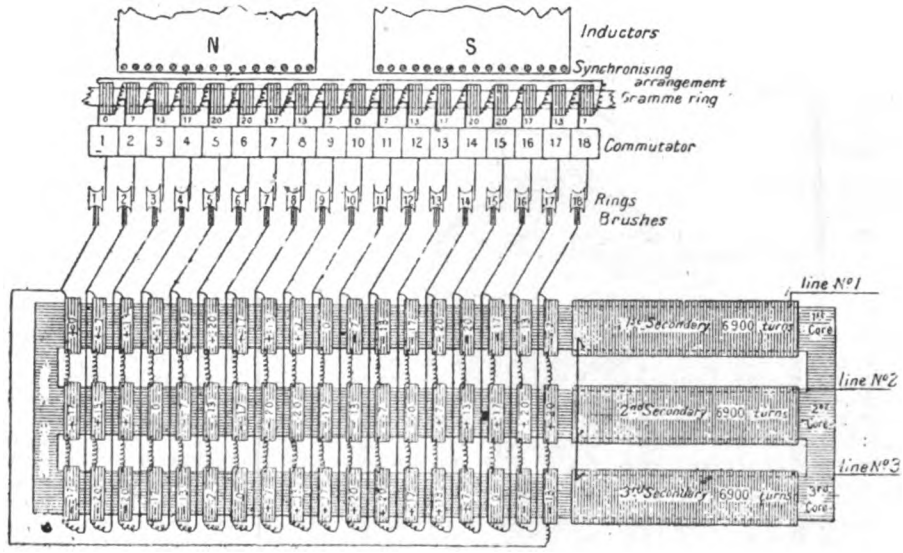

FIG. 16.

Experiments made with the Hutin and Leblanc system have given satisfactory results. The transmitting transformer was supplied at the commutator with a continuous current of 100 amperes at 200 volts. This was converted into triphase currents, and conveyed along a bare copper line at 6,000 volts. At the receiving end the current was transformed into direct current, which was used to charge accumulators. In Fig. 17 is given a curve showing the efficiency of the systems as found in the experiments.

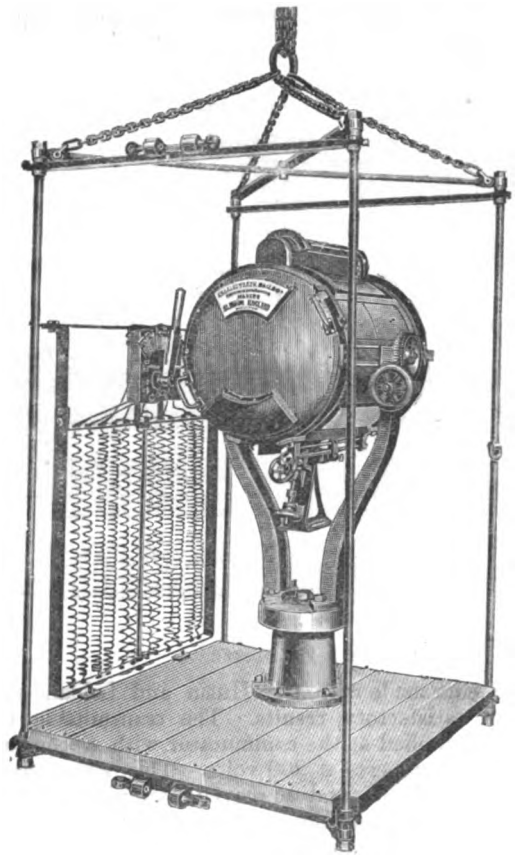
SEARCH-LIGHTS FOR CANALS.

In a previous issue we referred to the improved search-light plant introduced by Messrs. Baxendale and Co., of Miller-street, Manchester, for use on vessels navigating the Manchester Ship Canal at night. The plant, which is portable and always ready, comprises a small engine and dynamo combined, a search-light projector of the Admiralty pattern, and a mast arc lamp and reflector. The apparatus is of similar type to that which has been used for over 12 months for lighting vessels through the Suez Canal, where it has proved most effective and very satisfactory.

Our illustration represents one application of the search-light. The projector is shown mounted in a portable cage with an adjustable resistance on the left-hand side, and it is arranged to be fixed on the stems of vessels, the cage being suspended from a davit or spar, and clipped by the cramps attached to the cage. The projector barrel is 20in. diameter, rolled out of steel sheet, all the mountings being of gun-metal finished bright. The mirror is one of Messrs. Chance Bros.' best quality, 20in. diameter, 10in. focus, fitted in brass frame with a bayonet socket attachment to the barrel, so as to facilitate removal for cleaning, etc. A dispersing lens, also by the same firm, having an angle of divergence from 7deg. to 30deg., is attached by means of a hinged frame to the forward end of the barrel, in order to fantail the light, so as to spread it on the canal banks. The barrel is fitted with screw gear for focussing the lamp, and with worm and worm-wheel for vertical movement, and faced flanges on pedestal for horizontal movement. The electrical connections are carried inside the projector, and an instrument similar to a camera is provided at one

Digitized by Google

side of the projector for viewing the arc image thrown on ground glass. The hand lamp is made detachable, and is quite independent of the projector itself, the feed of the carbons being obtained by a right and left hand thread screw in the usual way, with a screw for raising and lowering the carbons. With carbons 25mm. diameter and a current of 50 amperes, this projector will illuminate a distance of 1,400 yards. A small combined engine and dynamo of the type supplied by Messrs. Hall and Co., of



Oldham, direct coupled, running at 500 revolutions per minute, with an output of 65 volts and 50 amperes at a steam pressure of 75lb. per square inch, are provided for working these projectors, with two attendants and the necessary accessories for working.

THE RELATION OF MATHEMATICS TO ENGINEERING.*

BY JOHN HOPKINSON, D.SC., F.R.S., M.I.C.E.

Mathematics has been described in this room as a good servant but a bad master. It will be my duty this evening to prove by suitable illustration the first half of the proposition, and to show the service mathematics has rendered and can render to engineers and engineering.

In our charter the Institution of Civil Engineers is defined as "A society for the general advancement of mechanical science, and more particularly for promoting the acquisition of that species of knowledge which constitutes the profession of a civil engineer, being the art of directing the great sources of power in [nature for the use and convenience of man, as the means of production and of traffic in states both for external and internal trade, as applied in the construction of roads, bridges, aqueducts, canals, river navigation and docks, for internal intercourse and exchange, and in the construction of ports, harbours, moles, breakwaters, and lighthouses, and in the art of navigation by artificial power for the purposes of commerce, and in the construction and adaptation of machinery, and in the drainage of cities and towns." No better definition can, I think, be found for our profession than that it is the art of directing the great sources of power in nature for the use and convenience of man. It covers all that the widest view of our work can include, and it excludes those applied sciences, such as medicine, which deal with organised beings. Mathematics has to deal with all questions into which measurement of relative magnitude enters, with all questions of position in space, and of accurate determination of shape. Engineering is a mathematical science in a peculiar sense. Medicine, the other great profession of applied science, has but little to do with questions of measurement of magnitudes or of geometry; but the engineer finds them enter into everything with which he has to deal, and enter in the most diverse ways. The thing he has to determine is that the means he employs is enough, and not unnecessarily more than enough to attain the end in view. For this he must numerically measure the end and the means, and see that they are justly proportioned to each other. It is useless this evening to waste time proving, what all will admit, that no one can be even the humblest engineer without a knowledge of arithmetic and enough of geometry to enable him to read a drawing, that some trigonometry, some rational mechanics and a knowledge of projections, is a very useful part of the mental equipment of a draughtsman. It is hardly necessary to call attention to the great economy in the labour of calculations effected by the use of logarithms, a mathematical instrument for which we are indebted to Napier. We may with more profit examine what use the higher mathematics can be to the practical engineer, and what has been done in the past for engineering by its aid.

Judging from etymology, mathematics must have been begun by engineers, for surely geometry is the work of the earth measurer or land surveyor. But since the prehistoric times when geometry was initiated, engineers have not added much that is new to mathematics. They have rather sought amidst the stores of the mathematician and selected the handiest mathematical tool they could find for the particular purpose of the moment, but have done little or nothing in return in the way of improving the tools which they borrow. In this respect the relation of engineering to mathematics differs much from its relation to experimental physics. In electricity, magnetism, and heat, engineers have from their practical experience repeatedly corrected the ideas of the theorists, and have started the science on more accurate lines. If our subject to-night had been the use of the practical applied science of engineering in promoting the development of pure mathematics, we should speedily find that there was hardly any material for discussion. The account being all on one side, let us see to what the debt of the engineer to the mathematician amounts.

There is no department of practical engineering in which the application of mathematics is more familiar than in that which relates to the calculation of the strength and rigidity of structures of various kinds. It is impossible to take up any book dealing with the subject without finding that it is crammed either with mathematical formulæ or with geometrical figures. The question is not whether mathematics is necessary to an adequate comprehension of the subject, but whether analytical or purely geometrical methods are more convenient. Of course, one might occupy many lectures in discussing the practical application of mathematics to the question of bridge building, roofs, guns, shafting, and the like. Our object must be to illustrate by various examples rather than to attempt anything like a complete discussion.

Consider the case of a long strut, so long that its transverse dimensions can be regarded as insignificant in comparison with its length. Whilst the strut remains perfectly symmetrical about its middle line, its strength will depend only upon the resistance of the material to crushing. Everyone knows that this would be an inadequate conclusion; we have to consider another element, namely, its stability—that is, we must examine what will happen to the strut if from any cause it is displaced somewhat from the direct line between its extremities. A mathematical discussion of the question results in a differential equation of the second order with one independent variable. Upon consideration of this we are enabled to see that if the thrust upon the strut be less than a certain critical value, a slightly bent strut will tend to return to its straight condition; but that if the thrust upon the strut be greater than this critical value the displacement will tend to increase, and the strut will give way. Further, that the critical value will depend upon whether one or both of the two extremities of the strut are held free, or whether they are rigidly attached by flanges or otherwise, so that the direction of the axis of the strut at this point must remain unaltered. Again, we infer that if the ends are held rigidly fixed, the length of the strut may be twice as great for a given critical value of the thrust as if the two ends are free to turn. We can also infer what the critical value will be for struts of various lengths and of varying cross-sections. This critical value depends not upon the resistance of the material to crushing, but upon its rigidity.

Another example, having a certain degree of similarity with the case of struts, is that of a shaft running at a high number of revolutions per minute, and with a substantial distance between its bearings; for simplicity, we will suppose that there are no additional weights such as pulleys upon the shaft. How will the shaft behave itself in regard to centrifugal force as the speed increases? In this case, so long as the shaft remains absolutely straight it will not tend to be in any way affected by the centrifugal force, but suppose the shaft becomes slightly bent, it is obvious to anyone that if the speed be enormously high this bending will increase, and go on increasing until the shaft breaks. In this case also we may use mathematical treatment; we find that the condition of the shaft is expressed by a differential equation of the fourth order, and from consideration of the solution of this equation we can say that if the speed of any particular shaft be less than a certain critical speed, the shaft will tend to straighten itself if it be momentarily bent, but that, on the other hand, if the speed exceeds this critical value, the bending will tend to increase with the probable destruction of the shaft. I do not know that either of these two questions can be properly understood without some knowledge of differential equations.

A problem having a certain analogy to those to which I have just referred is that of hollow cylinders under compression from without, such as boiler tubes. Whether the tubes be thick or

* The "James Forrest" lecture, delivered before the Institution of Civil Engineers, May 3, 1894.

Digitized by Google

thin, so long as they are perfect circular cylinders, they should stand until the material was crushed. But if the tubes are thin, what will happen if the tube from any cause deviate ever so little from the cylindrical form? The solution cannot be obtained without a substantial quantity of mathematics.

The next illustration shows how a mathematical conclusion, correct within the limits to which it applies, may mislead if applied beyond those limits, and how a more thorough mathematical discussion will give a correct result. Considering a case of shafting in torsion, it was shown by Coulomb that the stiffness and strength of a shaft having the form of a complete circular cylinder could be readily calculated if the transverse elasticity of the material and its resistance to shearing were known. From the complete symmetry about the axis it is evident that points which lie in a plane perpendicular to the axis before twisting will still be in that plane when the shaft is twisted; it is also clear that the angle through which all points in the same plane move will be the same; hence the problem was as simple as problem could be. But many who had occasion to make use of Coulomb's results gave them an application which was wholly unwarranted. They assumed that they were equally applicable to other cases than complete circular cylinders; they assumed, in fact, that every point of the material which lay in a plane perpendicular to the axis would remain in that plane when the shaft was twisted, whether the shaft was symmetrical about its axis or not, and they consequently arrived at very erroneous results. That the assumption was erroneous is obvious enough from a consideration of an extreme case. In Fig. 1 is shown in cross-section a hollow cylindrical shaft, which is not complete, but divided by a plane passing through its axis. In this case the shaft when twisted will be as illustrated in the side elevation; two points, A and B, were in one plane perpendicular to the axis when the shaft was free from twist; they cease to be in one plane when the shaft is twisted. St. Venant* in 1855 investigated the question of shafts without making incorrect assumptions; he expressed the condition of the material by a partial differential equation of the second order, and gave suitable surface conditions. A general solution of the problem for all forms of shafts has not been obtained, but St. Venant gives

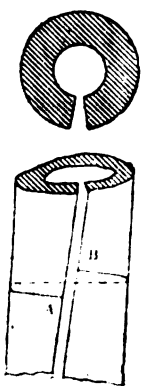


FIG. 1.

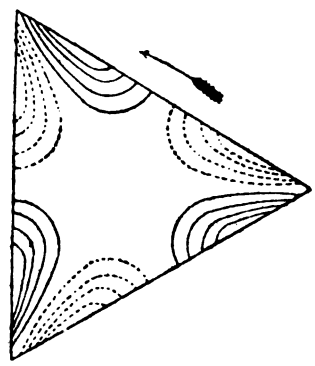

FIG. 2.

a number of solutions for particular forms, and he obtains some general results of interest. In all cases the stiffness of the shaft is less than would be inferred from an erroneous application of Coulomb's theory. Fig. 2 shows diagrammatically the strain in a shaft of triangular section; the full lines indicate that the parts of the shaft which lay in one plane before twisting, when twisted rise above the plane; the dotted lines indicate that they lie behind the plane of the paper. The shearing stress is least at the angles of the triangle, and is greatest at the middles of the sides. At this point, then, the shaft will begin to break under torsion. The fact is probably well known to men of practical experience, but it is directly contradictory to the conclusion at which one would arrive by a careless use of Coulomb's theory beyond the narrow limits within which it is applicable. The longitudinal ribs which one often sees on old cast-iron shafts are useful enough to give stiffness to the shafts against bending, but are good for very little if torsional stiffness or torsional strength is desired.

Another application of mathematical theory which has been carried somewhat further than the premises warrant is found in the case of girders. It is almost invariably customary to treat a girder as though the sections retain when the girder is bent the form and size which they had before bending. Making this assumption, it is very easy to calculate the strength and stiffness of a girder of any section. Unfortunately, the assumption is untrue; but, fortunately, it is approximately true in the case of most girders with which engineers in practice have to deal. That it is untrue can be readily seen from consideration of a girder of exaggerated form, the section of which is shown in Fig. 3. Any practical man would at once see that the outer parts of the flanges would add little to the strength of the girder, but according to the usual mathematical theory the outer parts of this flange should be as useful as the parts which are nearer to the web. This problem St. Venant also deals with in a rigid mathematical manner. Amongst other things, he showed that a girder of rectangular section, such as shown in Fig. 4, would, when bent, take the form shown by the curved lines in the same figure. The last two examples show how a little knowledge may be a dangerous thing, and how easy it is for anyone who attempts to apply mathematics without adequate mathematical knowledge to be misled.

The theory of thick cylinders under bursting stress from within has many important practical applications to hydraulic presses and to guns. It has been discussed more than once in this room. As usual in considering these cases, we are immediately led to differential equations which here are fortunately solved without serious difficulty, and the solution tells us the whole story. We learn that doubling the thickness by no means doubles the strength of the cylinder. And as a converse, that doubling the strength of the material will permit the thickness to be diminished to much less than one-half. Twenty-five years ago hydraulic presses were mostly made of cast iron. Many people were not a little astonished at the great reduction in thickness and weight which became possible when steel was substituted for the weaker material. In the case of guns it is well known that greater strength can be obtained if the outer hoops are shrunk on to the inner ones.* Mathematical theory tells us what amount of shrinkage should give the best results. It may possibly not be worth while to follow the results of theory precisely, but without the guidance of theory it would not be unnatural to give so great a shrinkage that the gun would be weaker than if no shrinkage were used.

The rolling of ships in a seaway gives an illustration of a principle which has very varied application in many branches of physics. Suppose a body is capable of oscillating in a certain periodic time, and that it is submitted to a disturbing force of given period, the equation of motion easily shows that the resulting disturbance will be great if the two periods are equal or nearly equal. We meet with the principle in acoustics as resonance. If two tuning-forks are tuned to the same pitch, and one is sounded in the neighbourhood of the other, that other will presently be thrown into vibration by the waves transmitted through the air from the first. You may try a similar experiment at any time on any piano. Strike the higher G in the treble, the sound ceases on raising the finger. Now hold down the middle C, and again strike G, the C string at once takes up the note sounded, and can be heard after the exciting string has been silenced by damping. The same fundamental idea is found in the lunar theory in the term in the equation known as the evection, and again in the theory of Jupiter's satellites. The reason why the metals present in the solar atmosphere give black lines in the spectrum by absorption, corresponding in position with the bright lines in the spectrum which the same metals give when incandescent, is again the same. Gas will absorb or take in from the ether waves of the exact period which it is capable of giving to the ether. The general

FIG. 3

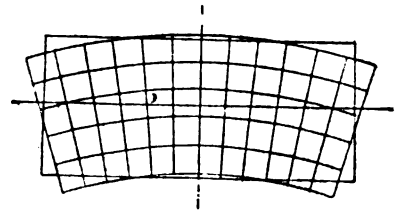

FIG. 4.

explanation of all these phenomena is easy. Imagine a pendulum, and suppose it experiences a periodic disturbing force, the first impulse of the disturbing force gives the pendulum a slight swing, the effect of the second impulse depends entirely on when it occurs—it may occur so as to neutralise the effect of the first, or it may occur so as to increase it. If the period of the force is the same as the natural period of the pendulum, the effect of the second, third, and later impulses will be added to the effect of the first, and the final disturbance will be great even though the individual impulses be minute. But the mathematical theory tells us much more than any general explanation can do. It tells us exactly what the character of the effect will be, and its amount if the periods are nearly but not exactly the same. It tells us, too, exactly how friction affects the results. And the beauty of it is that the mathematical theory is much the same in all cases, so that, having learned to deal with one case, we are enlightened as to a host of others. The oscillating body may be an ironclad, or it may be an atom of hydrogen, the disturbing periodic force may be the waves of the Atlantic, or it may be the waves in the ether occurring five hundred millions of millions of times in a second; it is all one to the mathematician, the treatment is substantially the same.

The question of the speed of ships and the power to propel them is probably more effectually treated by experiment on models, as was done by the late Mr. Froude, than by mathematics alone; but in order to learn from the experiments all they are capable of teaching a mathematical understanding is needed. Given that we know by experiment all about a given model, that we know what force is needed to propel it at every speed, we want to know from these experiments how a great ship, 100 times as big but similar in form in every respect, will behave, and here mathematics come in to aid us in making the inference.

The construction of ships at once leads us on to the methods of navigating them. In navigation I should find much material for my purpose, but navigation is not usually included in engineering, but many of the implements of navigation undoubtedly are. The mariner's compass has for ages been the mainstay of the navigator, and a simple enough instrument it was till it was disturbed by

* "Mémoires des Savants Etrangers," 1855; and Thomson and Tait "Treatise on Natural Philosophy."

Digitized by Google

the iron of which ships came to be built. The disturbance of the compass by the iron of the ship was first seriously attacked by two senior wranglers, Sir G. Airy and Mr. Archibald Smith. The disturbance may be divided into two parts—the first due to the permanent magnetism of the ship, the second to the temporary magnetism induced by the earth's inductive action on the iron of the ship; the first causes the semicircular, the second the quadrantal, error. One has only to open the "Admiralty Manual of Deviations of the Compass" to see how the mathematics of Archibald Smith have accomplished a proper understanding of the subject. The errors of the compass are dealt with in two ways: they are compensated by soft-iron correctors, and by permanent magnets so placed as to have an effect equal and opposite to the effect of the temporary and permanent magnetism of the ship; or they are dealt with by formulæ of correction which enable the error to be calculated when the course of the ship and the conditions of the earth's magnetism are given, or a combination of the two methods is used. Either method is based on Archibald Smith's theory. It is not possible to leave the subject of the mariner's compass without referring to the great improvements of Lord Kelvin. The improvements relate to every part of the instrument, and I venture to say that none of them could have been made by anyone but a mathematician. In order to get his card steady he knew that its period must be different to any possible period of the waves, or he would have the resonance, to which I have just referred, coming in, so he gave his card a considerable moment of inertia; but this was managed with a light card so that small needles could be used. If the needles are small, the correction by soft-iron masses and by permanent magnets is easier and more accurate. Then the bowl of the compass had to be suitably carried so that it would not be unduly disturbed by shock, and provision had to be made for damping by fluid friction the oscillations of the bowl if they occurred. Lastly, a most beautiful method of correcting the compass, without taking a sight, was discovered. In every detailed improvement one can detect that the inventing mind was that of a most able and trained mathematician.

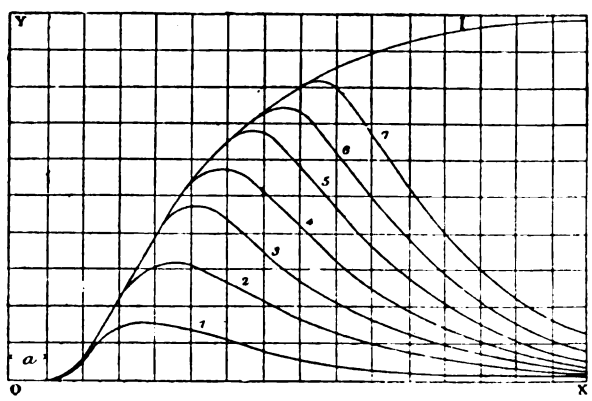

FIG. 5.

An essential of safe navigation is an efficient system of lighthouses. The optical problem of the lighthouse engineer is to construct apparatus which shall usefully direct all the light produced. The present forms of apparatus are in their leading features due to Fresnel, the able mathematician, who established on an absolutely firm foundation the undulatory theory of light. To properly design an optical apparatus formulæ must be used, and the advantage is great if the designer can with ease manufacture the formulæ he requires.

Submarine telegraphy yields some interesting examples of the application of the higher mathematics. When a cable across the Atlantic was first seriously entertained, the first point to be settled was, how many words a minute could be sent through such a cable. This was the most practical question possible. Upon the answer depended the prospect of the cable paying commercially if successfully laid. The matter was dealt with by Prof. Thomson,* of Glasgow, now Lord Kelvin. He showed that the propagation of an electric disturbance in a cable could be expressed by a partial differential equation, and that the solution of this equation under certain conditions applicable to practice could be expressed either by a definite integral or by an infinite series. The values of these were calculated, and hence before an Atlantic cable was laid at all it was known how long it would take a signal to reach the opposite shore, and how much its intensity would be diminished in transmission. Referring to Fig. 5, abscissæ represent time, reckoned from the time of making contact at the sending end of the cable, ordinates the currents at the receiving ends, curve (1) gives these currents when the contact at the receiving end, after being made, is continuously maintained. It will be observed that for a time, a, there is hardly any current at the receiving end, that then the current rapidly increases, and attains to half its final value after a time equal to about $5a$. Curves (1) . . . (7) show the currents at the receiving ends when the contact is made at the sending end maintained for times a, $2a$ . . . . $7a$ respectively, and then broken. Looking at curve (1) one sees how small is the amount of current and how long it lasts compared with the time during which contact is made. The time a depends on the length and character of the cable; it is equal to $k\,c\,l^2 \log_e \frac{4}{3}/\pi^2$, where k is the resistance per unit length, c the capacity per unit length, and l the length of the cable. The knowledge of what is the commercial value of a cable depends on a knowledge of the value of a, and this cannot be obtained without knowing the differential equation $c\,k\,\frac{dv}{dt} = \frac{d^2v}{dx^2}$,* to which I have referred, and its by no means simple solution either as a definite integral or as an infinite series. So far as I know, this piece of higher mathematics cannot be evaded by any mere elementary treatment. The transmission of disturbance in a cable is quite different from the transmission of sound-waves in air, which move with constant velocity. If the cable be doubled in length, it takes four times as long for the signal to pass through it instead of just twice as long, as would be the case if it were a proper wave motion. In fact, the time of passage between the making of contact at the sending end of the cable and the beginning of the resulting disturbance at the receiving end, varies as the square of the length of the cable. The mathematical theory is exactly the same as that of the transmission of heat in a plate, one surface of which is suddenly exposed to a temperature different to the temperature of the plate. This is constantly occurring in the application of mathematics—one piece of mathematical work serves for many physical problems having apparently little in common. Fourier long ago discussed the heat problem, little dreaming that his analysis would be just what was wanted for ascertaining how fast signals could be sent across the Atlantic by a system of telegraphy which in his days had not even been projected in its simplest form. The same differential equation also gives the theory of the transmission of telephonic messages through cables; but the solution is then easier, and tells us exactly why it is so much more difficult to speak through 100 miles of cable than through 1,000 miles of overhead line. As I have just stated, the differential equation of the disturbance in the cable is $c\,k\,\frac{dv}{dt} = \frac{d^2v}{dx^2}$. A musical note of period T spoken into the cable through a telephone is properly represented by $A \sin \frac{2\pi t}{T}$; the disturbance in the cable will be:

$$v = A\, e^{-x\sqrt{k\,c\,\pi/T}} \sin\left(\frac{2\pi t}{T} - x\sqrt{k\,c\,\pi/T}\right);$$

as may be easily verified by differentiating. This equation tells us everything. It tells us the rate at which the waves diminish with the distance. This rate increases with the resistance, with the capacity, and with the frequency. If the capacity is at all considerable, the diminution is rapid. The velocity of the waves is not the same for all frequencies, as is the case with waves in air, but varies as the square root of the period, so that if two notes were sounded the high note would arrive after the low notes, and the resultant effect would be entirely destroyed. Here, again, it is difficult to see how the differential equation and its solution can be evaded.

Though the history of the telegraph dates only from a little more than 50 years ago, it is ancient in comparison with the other great applications of electrical science, which have received their development during the last 15 years. Here, again, mathematics which are not quite elementary have played their part. In the theory of transformers we find another illustration of the need of knowing how formulæ are obtained if they are to be correctly applied. The early transformers were made with unclosed magnetic circuits; there was an iron core, but the lines of magnetic force passed through air for a considerable part of their path. In this case a complete mathematical theory was not very difficult. But speedily-closed magnetic circuits were found to be better, and the relation of magnetic induction and magnetic force became all-important. If anyone were to apply mathematical formulæ which were true for the earlier transformers to the later ones, his results would be inaccurate. Indeed, a wholly different method of attack on the problem was needed, taking account of the facts as they are, and not applying results which were true of older apparatus to cases essentially distinct.†

The employment of alternating currents has brought into use, as a necessity for understanding the actually observed phenomena, a great deal of mathematics. Why is the apparent resistance of a conductor greater for an alternating current than for a direct current? And by resistance I do not mean the quasi-resistance due to self-induction.‡ The mathematical electrical theory is ready with an answer; it is ready, too, to tell us how the difference depends upon the frequency of the current and on the size of the conductor. In the case of a cylindrical conductor the solution involves a knowledge of Bessel's functions. We learn that if the current has a high frequency, or if the conductor be large, there will be very little current in the centre of the cylinder, and that therefore for any practical purpose the centre of the cylinder might just as well not be there; the current is largely confined to the part of the conductor near to its surface. The currents at different depths in the conductor attain to their maximum values at different times; those near the surface of the cylinder occur before those at some distance from the surface. The mathematical conditions are expressed by the same equation as is used to express the disposition of heat in a cylinder the surface of which is submitted to a periodic variation of temperature. Anyone who had

Digitized by Google

thoroughly mastered the heat problem would be quite prepared to deal with the problem of currents in a conductor. It cannot be too often repeated, any piece of pure mathematics which finds one application to a physical problem is almost sure to find, in exactly the same form, applications to other problems which superficially are absolutely distinct. The differential equation in this case is $k c \frac{d v}{d t} = \left(\frac{d^2 v}{d r^2} + \frac{1}{r}\frac{d v}{d r}\right)$, the similarity of physical condition to the problem of linear propagation of heat is close, but the mathematics differs materially owing to the presence of the term $\frac{1}{r}\frac{d v}{d r}$ in the equation. Mathematics deals with the relation of quantities to each other without troubling as to what the physical meaning of the quantities may be. Hence it is that the mathematical treatment of two such problems as the distribution of currents in a cylindrical conductor and of heat in a cylinder is identical, whereas the treatment of the distribution of heat in a cylinder is quite distinct from the treatment of the distribution of heat in a sphere or in a solid bounded by two parallel planes.

A curious phenomenon was observed in the large alternate-current machines at Deptford when connected to the long cables intended to take the current to London. The pressure at the machines when connected to the conductors was, under certain conditions, actually greater than when not so connected. The phenomenon is one of resonance very analogous to the heavy rolling of ships when the natural period of roll is about the same as the period of the waves.* The period of the alternating current corresponds to the period of the waves, the self-induction of the machine to the moment of inertia of the ship, the reciprocal of the capacity to the stiffness of the ship, and the electrical resistance of the conductors to the frictional resistance to rolling. The mathematics in the two cases is then the same. The effect was predicted long before it was observed in a form calculated to cause trouble.

A problem which is still agitating electrical engineers is that of running more than one alternate-current dynamo machine connected to the same system of mains. Before the matter became one of practical concern, it was considered in this room, and it was shown mathematically that it was possible to run independently-driven alternators in parallel, but impossible to run them in series. That is to say, that if two alternators were connected to the same mains they would tend to adjust themselves in relation to each other so that their currents could be added, but that if an attempt were made to couple them, so that their pressures should be added, they would adjust themselves so that their effects would be opposed.†

Perhaps of all engineering problems which have received their solution in the last hundred years that of the greatest practical importance is the conversion of the energy of heat into the energy of visible mechanical motion. The science of thermodynamics has advanced along with the practical improvement of the steam-engine. By its aid, particularly by the aid of the so-called second law, we know what is possible of attainment by the engineer under given conditions of temperature. I must not trench on the subject of one of my successors, but I may point out that our knowledge of the second law of thermodynamics was first developed by means of mathematics, and that to-day its neatest expression is by means of partial differential coefficients. The two most notable names in connection with the development of the second law of thermodynamics in harmony with the first are those of Kelvin and Clausius; both dealt with the subject in a mathematical form not comprehensible to those who have not had substantial mathematical training.

Illustrations such at these might be multiplied almost indefinitely. They show that the advancement of the science of engineering has been aided in no inconsiderable measure by the labours of mathematicians directly applying the higher mathematical methods to engineering problems. They show, too, one way in which respect for a formula may be dangerous, one way in which it is true that mathematics may be a bad master. In St. Venant's problems we have an example in which the use of older results of limited application in cases where the assumptions on which they rest are not true will mislead. The examples show the proper remedy. It is a more complete application of mathematical methods. The error is just one which a man will make who has the power to use a formula without a ready understanding of how it is arrived at. A practical man, ignoring mathematical results, might or might not escape the error of supposing that a triangular shaft would break at the angles under torsion. The half-educated mathematician would certainly fall into the snare from which complete mathematical knowledge would deliver him. You can only secure the services of that good servant, mathematics, and escape the tyranny of a bad master by thoroughly mastering the branches of mathematics you use. The mistake caused by the wrong application of mathematical formulæ is only to be cured by a more abundant supply of more powerful mathematics.

There is another drawback to the use of results, taken, it may be, out of an engineering pocket-book by those who are not prepared to understand how they are reached and on what foundations they rest. The educational advantage is lost. The close observation which enabled the earlier engineers to proportion their means to the ends to be attained was no doubt very laborious, and the results could not be applied to cases much different from those which had been previously seen, but the effect on the character of the engineer was great. In like manner, to thoroughly understand the theory of an engineering problem makes a man able to understand other problems, and, in addition to this, precisely the same mathematical reasoning applies to many cases. The mere unintelligent use of a formula loses all this; it leaves the mind of the user unimproved, and it gives no help in dealing with questions similar in form though different in substance.

But even the use of mathematics by competent mathematicians is not without drawbacks. Mathematical treatment of any problem is always analytical—analytical, I mean, in this sense that attention is concentrated on certain facts, and other facts are neglected for the moment. For example, in dealing with the thermo-dynamics of a steam-engine, one dismisses from consideration very vital points essential to the successful working of the engine, questions of strength of parts, lubrication, and convenience for repairs. But if an engineer is to succeed, he must not fail to consider every element necessary to success. He must have a practical instinct which will tell him whether the instrument as a whole will succeed. His mind must not be only analytical, or he will be in danger of solving bits of the problems which his work presents, and of falling into fatal mistakes on points which he has omitted to consider, and which the plainest intelligent practical man would avoid almost without knowing it.

Again, the powers of the strongest mathematician being limited, there is a constant temptation to fit the facts to suit the mathematics, and to assume that the conclusions will have greater accuracy than the premises from which they are deduced. This is a trouble one meets with in other applications of mathematics to experimental science. In order to make the subject amenable to treatment, one finds, for example, in the science of magnetism, that it is boldly assumed that the magnetisation of magnetisable material is proportional to the magnetising force, and the ratio has a name given to it and conclusions are drawn from the assumption, but the fact is, no such proportionality exists, and all conclusions resulting from the assumption are so far invalid. Wherever possible, mathematical deductions should be frequently verified by reference to observation or experiment, for the very simple reason that they are only deductions, and the premises from which the deductions are made may be inaccurate or may be incomplete. We must always remember that we cannot get more out of the mathematical mill than we put into it, though we may get it in a form infinitely more useful for our purpose.

Engineers, no doubt, regard their profession from very different points of view: some think it a mere means of making money, some regard it as an instrumentality for benefiting the race, whilst others, again, delight in it as an interest in itself, and delight in it most of all when new knowledge is added to that which we know already. It is just the same with the medical profession: some attend patients for the guineas they receive, some give a very high place to motives of benevolence, whilst others love it as a field where new knowledge may be found and the delight of discovery enjoyed. In regard to the first class of engineers, I have no doubt a little skill in managing a board of directors or impressing a committee of Parliament will be much more useful than a great deal of mathematics. Let him manage his board and buy his mathematician, and it is very probable he will make much more money than the mathematician or any other person of skill whom he may employ. But we cannot all of us make money in this way. In the future it is likely that educated men will have to work harder and receive less, and it is a great thing if their work can be made itself a joy, and surely this can best be by a thorough understanding of the reason of all they do by the feeling that they have full competence to form their own judgments without depending much on the authority of others. This can only be, in the words of Sir John Herschell, by a "sound and sufficient knowledge of mathematics, the great instrument of all exact enquiry, without which no man can ever make such advances in any of the higher departments of science as can entitle him to form an independent opinion on any subject of discussion within their range."

After all, in any department of applied or pure science the highest satisfaction comes from accomplishing that which no one has done before, from disclosing what no one hitherto has shown. If a department of the arts or sciences ceases to advance and becomes simply the application in known ways of known principles to obtain known ends, that department has lost its charm till the time comes for a fresh advent of change and development. To effect such advances it is easy to show that mathematics is a most necessary instrument. Here it is no drawback that the mind of the discoverer is too analytical; he may deal at his pleasure with one aspect of a problem, and it does not detract in any way from the value of his solution that he does not touch on incidental matters. Some of you who love the interest of continual advance in our science and practice, may look forward with a shade of sadness to a possible time when all is done or known which can be done or known, and the work of the engineer shall be merely applying principles discovered by his predecessors. In such a state, when the experience of the older generations shall control the practice of to-day, the free use of mathematical methods may be effectually superseded by the application according to rule of mathematical formulæ. But it would be a much less interesting condition than the constant change of to-day, when the practical experience of 10 years ago is in many departments rendered worthless by later discoveries. But we need not fear that such a time of petrifaction will come so long as, whilst reverencing the discoverers who have added to our knowledge, we endeavour to replace their methods by better, and expect that those who come after us will, in their time, improve upon ours. Our knowledge must always be limited, but the knowable is limitless. The greater the sphere of our knowledge the greater the surface of contact with our infinite ignorance.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom.....	3s. 3d.	6s. 6d.	13s. 0d
Other Places.....	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XII. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

PROF. KENNEDY AND CHEAP CRITICISM.

We are somewhat interested in the statement made in the presidential address to the Mechanical Engineers to the effect that "it is a favourite bit of cheap criticism indulged in by those who have not to supply energy on a large scale at the expense of those who have; that the former class of folk show their ignorance of their own work and interests by neglecting to obtain that enormous demand for motive power which would come on them if they only reduced their prices low enough." The whole paragraph containing this sentence is to the same effect. Now we have indulged in a good deal of this cheap criticism, but we do not think that Prof. Kennedy translates our arguments justly, nor, indeed, do we know if he had any of our remarks in mind when writing his sentences. It is certainly very much due to the aid of this species of cheap criticism that the public mind is enlightened upon any point. Very often, indeed, the criticism may be crude, may even be incorrect, but the crudities will be toned down as knowledge increases, and the incorrectness can be corrected by those who know better. A wholesale condemnation of criticism fails in its object. We are not all-infallible—we do not pretend to be—but we do pretend to have given some slight attention during the past twenty years to the matter of electrical development; and our own conclusion is that in very many instances consulting engineers have failed to provide in their schemes for possible developments. Surely Prof. Kennedy would not have us "rest and be thankful" with the distribution of electric energy for lighting purposes. Electric lighting came first as a luxury—it will end by being a necessity; and we think electric lighting never had the arguments in its favour which can be put forward in many cases for the use of electric energy for power purposes. No one who has considered the subject has, so far as we know, suggested that distribution for power purposes would be immediately successful commercially in all districts. That would be absurd, but even Prof. Kennedy admits there are selected districts where a considerable amount of power might be furnished if the cost was sufficiently low.

We have very strong opinions as to the duties of technical journals. In the first place, they must be convinced that the development suggested is possible, and on that score, so far as the distribution of electric energy is concerned for either light or power purposes, we are agreed. Secondly, they have to determine roughly whether the suggestion, if carried into practice, will result in economy (1) generally or (2) only in special cases. On this latter point agreement is pretty universal. We have ourselves more than once instanced the district around Fleet-street, wherein there are hundreds of small steam-engines—say from 2½ h.p. to 10 h.p. nominal—wherein, too, other hundreds have been replaced by gas-engines. This type of steam-engine, especially worked, as many of these are worked, very intermittently and far from fully loaded, cannot be said to be economical. Again, the space occupied by the engine and boiler is valuable, and can be better utilised by erecting thereon another machine. But so far as this

Digitized by Google

district is concerned, it seems we are all agreed. Our investigations tend to show that in almost every large town there are numbers of users of such uneconomical combinations that, no matter if the electrical energy were supplied at lighting terms, it would be better to use it than the old ramshackle steam-engine now in use. The reference of Prof. Kennedy to gas companies is particularly unfortunate. These companies are straining every nerve to get gas introduced for heating purposes, and we have very little doubt but that a different rate might have been in the first place obtained by users of gas for power or heating purposes had there been any prospects of keen competition from any other source.

There is no demand even in Fleet-street for electrical energy for power purposes, because we all know it cannot be had, and business men don't cry for the moon, if children do. The same may be said of Mayfair, but there the argument is different. The power there would be more in the shape of a luxury, and we are not sure that motors for lifts, or for boot and knife cleaning, are silent enough for these aristocratic mansions. We do not think, in fact, the time has yet come to say the distribution of electrical energy for power purposes is as advocatable—to coin a word—in purely residential as in some business quarters. Lastly, we should advocate in many instances electrical energy for power purposes on the score of expediency.

After all, we do not think Prof. Kennedy will differ largely from us. There is no necessity to chop logic as to whether the demand must first be created, or the supply be in readiness. Nor is it necessary to do more than refer to large factories. The power they use is far more economically obtained than that of small users. We believe that under many conditions the supply of electric energy is possible and is economical, that such supply would be advantageous to central-station work, and that the demand for it should be fostered.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE VARLEY TESTIMONIAL.

SIR,—I would ask to be allowed, through the medium of your columns, to express my deep obligation to the members of the testimonial committee for having so gracefully recognised my services to applied science in the circular they issued shortly after the formation of the committee. I would also ask to be permitted to return my sincere thanks to all those who have subscribed to the testimonial fund.

My thanks are I feel in a special sense due to Lord Kelvin for so kindly accepting the post of chairman, and for taking an active part as leading member of the committee. I wish also to express my deep obligation to the three executive members on whom the work has chiefly fallen—viz., Mr. Crompton (the hon. sec.), Mr. Gatehouse, and Mr. Stroh (the treasurer).

And now that the testimonial fund has been brought to a close, I find it difficult to realise that nearly nine years have elapsed since I was first looked up on behalf of leading firms who refused to recognise the claims asserted by the Anglo-Brush Corporation.

At that date, for reasons which came out in evidence in the law courts, I was reluctant to take the initiative in asserting my claims as the inventor of compound winding, but when my anticipation of the Brush patent had been brought forward publicly in the interests of the dynamo industry I considered that I owed it as a duty to myself, as well as to the trade, to establish the priority of my invention, and from that time I regarded the matter as a duel between Brush and myself, and a battle with the scientific experts who were assisting the Anglo-Brush Corporation.

In the beginning of December, 1887, to my very great regret, the firms in whose interest I had been originally looked up, retired from the defence, and a compromise altogether in the favour of the Brush Corporation was arranged.

An article recently published in the *Pall Mall Gazette*, headed "At a Vigintave," throws a side light on how it came about that wealthy English firms should have given way without fighting a battle. In the article I am referring to Colonel Gouraud is reported to have said, "I am a firm believer in litigation as the only test of a patent's merit. Look at the telephone, now. The very first thing I did when I got a wire from Edison to say that he had invented a telephone and wanted me to take it up, before I had even seen the instrument, was to go off and retain the three best patent counsel in the kingdom. The result is that we have never lost a case."

Now, the Anglo-Brush Corporation acted on similar tactics to those of Colonel Gouraud; they retained Sir Richard Webster, Moulton, and other of our ablest counsel, as their legal advisers, and as scientific experts they retained Sir William Thomson (Lord Kelvin), Sir Frederick Bramwell, Messrs. Latimer Clark and W. H. Preece, Profs. Perry, Silvanus Thompson, etc.

It is a matter of history that all the more important electrical cases previous to that of Brush *v.* Crompton, with the single exception of Wilde *v.* Gramme, had been mainly won by the ability of counsel, the official status, and the clever special pleading of scientific experts; and that being so, the defendants in the case of Brush *v.* Crompton, although they had no manner of doubt as to the soundness of the defence, considered themselves to have been strategically outmanœuvred, and under the circumstances they came reluctantly to the conclusion that discretion was the better part of valour.

So soon as I was advised that a compromise had been arranged, I determined to try and get the case reopened, and in a series of articles published in the *Electrical Review* I discussed the respective claims of Varley and Brush to be considered the first to have described a system of compound winding.

In the course of my articles I expressed the opinion that the trade had allowed the Anglo-Brush Corporation to simply walk over the course, and that it seemed to me they had acted very shortsightedly in doing so. I stated it required no prescience to foresee that the next step on the part of the Brush Corporation would be to apply for a prolongation of their patent, and, I added, who shall blame them, seeing that under the circumstances they would probably be successful? I also directed attention to the fact that the previous attempt of the proprietors of the Wilde patents to obtain a monopoly of the dynamo industry had been successfully resisted,* and referring to what I would now term "Gouraud tactics," I said a feeling had been growing upon me for some time that there was need for a new strategy, that it was seldom sufficient to act solely upon the defensive, decisive victories being obtained were often than not by flank marches, and attacking the base of operations. I then proceeded to

* In the lawsuit of Wilde *v.* Gramme, the proprietors of the Gramme patents, who were foreigners, finding themselves involved in very considerable expenditure, resolved to withdraw from the defence. I regarded their doing so as little short of a catastrophe, as I foresaw it would probably result in the formation of a wealthy syndicate, and the making the dynamo industry a close monopoly. Under these circumstances I offered my professional services on the side of the defence gratuitously, and I had the unique advantage of being the sole scientific adviser. Wilde was successfully resisted, the battle being practically won at the disclaiming stage, as leave to disclaim was refused, and when the case was called in court it was allowed to go by default, Wilde paying costs.

Digitized by Google

analyse the affidavits sworn to on behalf of the Anglo-Brush Corporation, and after showing how weak they really were, I said if the trade would rally round me I would make it a life and death struggle, and take the matter up with a determination to win.

The outcome of my articles was that Messrs. King, Brown, and Co., of Edinburgh, decided to oppose the Anglo-Brush Corporation, and I was given a verbal assurance that they would carry the case through the Scottish courts, and, assuming they were successful if the case were taken to the House of Lords, they would fight it there.

Instead of waiting to be attacked, Messrs. King, Brown, and Co. assumed the offensive, and as English counsel cannot plead in Scotland, this strategy checkmated the "Gouraud tactics," for it broke up that organisation of able barristers and scientific experts who had won electrical case after electrical case in the English courts, and, as a consequence, the battle was fought out on less unequal terms than it otherwise would have been.

When the time for hearing the case for the reduction of the Brush patent was drawing near, the Anglo-Brush Corporation tried to arrange a compromise, and they offered terms favourable enough for the legal advisers of Messrs. King, Brown, and Co. to advise their clients to accept. I energetically opposed any compromise being come to, and the raising a guarantee fund was offered me as the alternative. I at once issued a pamphlet to the trade, and brought my personal influence to bear also; a guarantee fund was raised, and the respective claims of Varley and Brush to be considered the inventors of "compound winding" were fought out in the Court of Session, Edinburgh, in November, 1888. Some months later judgment was given altogether in favour of Varley, and on appeal this judgment was not only sustained, but strengthened.

The immediate effect of the second judgment delivered in the Scotch Courts was that the Anglo-Brush Corporation found it necessary to liquidate and to reconstitute themselves as a new company. The case was, however, carried to the House of Lords, and, as is well known, the Lords delivered judgment on April 4, 1892, and, without hearing counsel on behalf of King, Brown, and Co., they declared Varley to be the inventor of compound winding.

The part I have been permitted to play in respect to the dynamo, it must be admitted, is unique. The discovery of what Lord Kelvin has aptly named the dynamo principle is admittedly one of the greatest discoveries of the century. I was the first to discover this principle, and the original dynamo, constructed in August, 1866, and provisionally protected in December of the same year—the first machine made of the type of dynamo now in use—and for the designing of which I was awarded the gold medal of the Inventions Exhibition of 1885, is at the Patent Museum, South Kensington. I am also the inventor of the second great advance in dynamo construction—viz., compound winding. My claims to this invention have been thoroughly sifted by the highest courts in Scotland and the United Kingdom, and, although opposed by a most powerful financial corporation, assisted by the highest legal and the scientific talent, whatever claims I have urged as the first inventor, have been fully sustained in each of the three judgments delivered.

I have the satisfaction of feeling that in the course of my life it has fallen to me to make advances both telegraphically and electrodynamically; I have the satisfaction of feeling also that I have been the means of rescuing the industry from being made in no small degree a monopoly.

I might be forgiven, I think, were I to take credit for having invented a legal strategy which enabled me to successfully deal with an organisation having its origin in the Government telegraph monopoly, but which had been developed by powerful financial corporations into what seemed to be an all-powerful machine for crushing out private enterprise; but if I take credit to myself for pioneering a new strategy, I do not overlook the fact that it would have been of no avail but for the public spirit of a Scotch firm, who took upon themselves the responsibility and incurred considerable expenditure in fighting what was really the trade's battle, rather than their own.

The pecuniary gain to the industry which has resulted from reopening the case after the trade had given way, must have been very great. To myself the period now being brought to a close has been one of labour and great mental anxiety, for I have felt all along the heavy responsibility I undertook when I urged the trade in 1887 to rally round me and resist. I took up the case, as I promised, with the determination to win; and in carrying it through to success I have given my time, in no small degree, gratuitously.

A list of the names of those who have subscribed has been given me, and I am very pleased to find among the subscribers the names of men of the highest distinction in physics, in electrical engineering, and electric pioneering, and the legal profession, but at the same time I confess it is depressing to me to find that, with the exception of a few of the more distinguished members of the dynamo industry, the manufacturers who, as a whole, must have largely benefited from my successful efforts to overthrow monopoly, should not have responded to the invitation of the committee.

I feel very much indebted to the committee, and therefore I hope I shall not be misunderstood when I say I am sorry it has been found necessary to protract their proceedings over so long a period; memories are short in these days of high pressure, and when one has arrived at the wrong side of sixty, two years is a considerable portion of his life.

I am pleased to be informed that Lord Kelvin is exerting his exceptionally powerful personal influence to carry successfully through a resolution passed at one of the meetings of the committee. It is very important to me that his efforts should be crowned with success. The matter, I am sure, could not be in better hands, and I shall always feel that Lord Kelvin has placed me under a special obligation.—Yours, etc.,

S. ALFRED VARLEY.

53 and 54, Chancery-lane, W.C., April 28, 1894.

DECIMAL NOMENCLATURE.

SIR,—Everybody will thank Mr. Hayward for his communication in last week's issue. His suggestions are at once original, ingenious, and linguistic in the highest degree. The new system, if introduced into our schools, would, we may be sure, do more to stimulate the critical faculties as well as the power of memory, patience, and elocution than whole volumes of verses. There has hardly been so refreshing a novelty presented to the engineering world—never too gay—since the happy day when we began to "squirm" up and down stream in electric launches. But this beautiful and expressive verb sinks into insignificance by the side of Mr. Hayward's elastic piece of mechanism, which dekens and dekets away, without any hitch, to an indefinite extent in either direction. The examples that he gives should be convincing as they stand; but the following specimen of a calculation may help to dispel any remaining doubts as to the merits of the system.

Example (taken from Prof. Ayrton's "Practical Electricity," page 327).—Find the work required to separate the plates of a given condenser, the necessary data being given.

Capacity before separation equals (2 dideks 8 deks and 8 over 4 and 4 dekets 5 didekets 2 tridekets by one-third of a deket) dodecafaradets, or 1 and 9 dekets 4 didekets of an enfaradet.

After separation it becomes 6 and 4 dekets 6 didekets 7 tridekets of an octafaradet. Hence if K = charge, and V the P.D. after separation,

K = 1 and 9 dekets 4 didekets by an ennadeket by 2 dideks 5 deks;

= 6 and 4 dekets 6 didekets 7 tridekets by V, whence V = 7·5 divolten.

The store of energy before separation = (1 and 9 dekets 4 didekets by 2 dideks 5 deks squared over 2 and 7 dekets 1 deket 2 tridekets) enna foot-poundets; and

After separation (1 and 3 dekets 4 didekets 1 trideket) tetra foot-poundets, from which it is obvious at a glance

Digitized by Google

that work done in separation = (8 and 9 dekets 3 didekets 9 tridekets) penta foot-poundets.—Yours, etc.,

TRIAMPERET ALIAS MILLIAMPERES.

Thames Ditton, May 2, 1894.

ELECTRIC TRACTION IN RAILWAY TUNNELS.

BY FRANK B. LEA.

There are short railway tunnels and there are long ones. It is, of course, with the latter that we have to deal, for the special benefits of electric traction as compared with the use of steam locomotives can only then be said to come into play when considered in regard mainly to the important matter of ventilation.

The object of tunnelling—the reason for the existence of these magnified rabbit holes—is either to avoid the expense of surface wayleaves over enormously valuable land—as, for instance, in the case of the underground railways which are becoming such a marked feature of transit systems generally in London and other large towns—or else to penetrate a hill, and thereby also avoid great expense in working a line with excessive gradients otherwise rendered necessary. In the first class of long tunnels there is obviously no superior rival to electric traction, as appears evident from results on the City and South London Railway, and also from the plans set forth for lines situated similarly. With all due deference to the wisdom and experience of those in authority over the Metropolitan, the District, and the Mersey Tunnel lines, etc., it may be doubted whether any steam-operated railway underground can achieve reasonable success, for in proportion as the atmosphere generally of a *soi disant* civilised country becomes more and more carboniferous, its inhabitants will be forced to take every opportunity of amending in detail the conditions of life. If the production of smoke and sulphur is essential in certain directions, the number of instances where this is not the case will be reduced as much as possible.

It is, however, with reference to the second type of railway tunnels that these remarks are more especially written, since there is, even at the present time, a much larger scope than would be imagined for the use of electric traction in this way. Quite recently, for instance, a leading daily newspaper published some details of the excessive inconvenience, if nothing more, which is apparently a matter of everyday life with the railway officials engaged on the St. Gothard and Mont Cenis routes. In passing through the long tunnels, engine-drivers, stokers, and guards have more than once been almost wholly overcome by the foul air, which under certain conditions cannot very readily be dispersed even with the usual ventilating appliances; and the same thing will be found on other lines in mountainous districts where tunnels are both numerous and long. This very fact, however, points at once to the remedy, for if electric traction were introduced on the hilly sections of these lines, it would not only be in most cases quite possible, but also much more economical to employ adjacent water powers as the prime source of tractive energy instead of using poor and expensive qualities of foreign coal or artificial fuel, in the shape of briquettes, for the purpose of raising steam in the locomotives, whose smoke is so offensive and troublesome, and whose efficiency is not so great in proportion as that of their electrical counterparts.

In many cases, it may be objected, the heavy weight of a steam locomotive is actually required for adhesion purposes on such lines, where steep gradients are almost always prevalent; but here, again, the remedy is obvious. A good system of rack railway like, for instance, that invented by Mr. Abt, and now so extensively coming into use on main lines as well as branches, would provide ample means for climbing heavy inclines with the light motors required in electric railway work. In this way, a still further gain in the operating expenses may be effected, for there are very few steep grades which do not necessitate the use of two locomotives even with ordinary trains. An electric rack locomotive will, however, pull a far greater train load—in proportion to its dead weight—than could ever be hauled by steam adhesion locomotives of equal power. Upon a gradient, for instance, of 1 in 25—by no means an uncommon or excessive incline, even upon main-line railways running through a mountainous country—the weight of steam locomotive necessary for adhesion purposes in propelling a train of 125 tons weight would be at least 50 tons; and even this train load would be too much whenever the rails should happen to be greasy. There is under such circumstances, therefore, a dead weight in the locomotive of at least 10 tons for every 25 tons of train weight. An electric rack locomotive, *per contra*, will not weigh more than about 25 tons for the same tractive force, yet by its use the train weight could be increased to 150 tons, or a proportion of 10 tons dead weight in the locomotive to 60 tons of train weight.

Of course, some amount of engine weight is necessary even in the rack system, but it may be materially reduced in this way far more than is possible with adhesion locomotives. To put the matter briefly, the ratio of tractive force to engine weight in adhesion systems can rarely be allowed to exceed 1 in 5: more usually it is less. With a rack, however, like that devised by Abt, the ratio is nearly reversed, for the engine weight needs only to be about one-quarter of the tractive force to overcome the tendency of the rack pinions to climb out of gear.

Emphasis has been herein laid on this point to show how easy it is to cope with *all* the difficulties inherent to mountain lines where long tunnels are numerous, and entail great inconvenience both to passengers and train staff. The use of heavy steam locomotives, two or even three to a train in ascending steep grades, with their strong tendency to smoke when fully loaded and fed with poor fuel, is not in any way essential to the proper conduct even of a main-line service. The rack locomotives need not be confined to such short parts or sections of the line as appear to require the use of a rack: they may be so constructed as also to work by adhesion upon the less hilly portions. Indeed, they can with advantage be worked upon the entire mountain section—say, for instance, in crossing the Alps or any other great range—where water power is usually available in a cheap and easily-applied form for the generation of electric energy at fixed points, whence it may be carried in the ordinary way along the line.

On the score of improved ventilation, there are evidently, then, strong reasons for adopting electric locomotives upon such lines: it might doubtless be possible to erect blowing engines or huge fans for creating a powerful current of air through long tunnels, but the same expenditure on plant would almost cover the cost of a complete electric equipment, whilst obviously the total working expenses would be higher in the former case than when steam is abolished altogether. More might be said in this connection with regard to the much greater safety and ease of control afforded by the rack system when descending steep grades, but this feature, although important, hardly concerns the question of long tunnels and how to work them. The chief advantage remains, that the air within a tunnel may, by the use of electric traction, be kept as pure and healthy as that outside; whilst, as, of course, quite a minor item of information, railway managers may be pleased to hear that the cost of working the line would in nine out of ten such cases be materially reduced. Any other conclusion it would be impossible to reach when we are, for instance, told that the cost of fuel on the Canadian Pacific—a typical railway of the kind—is as much as 11d. per locomotive mile.

THE TRANSMISSION OF ELECTRICAL ENERGY BY HIGH-TENSION SERIES DYNAMOS.

Herr Ernst Schultz, of Aix-la-Chapelle, in an article in the *Elektrotechnische Zeitschrift* on the transmission of electrical energy by means of high-tension direct current by means of series dynamos, says that under certain circumstances the employment of series machines offers advantages over the employment of compound dynamos and shunt electromotors. In recognition of this fact, the Deutsche Elektricitätswerke of Aix-la-

Digitized by Google

Chapelle, in power transmission plants where there is only one motor at the secondary station, have employed series machines, and the practical results have accorded with the theory.

One of the installations in question is that of Herr Cuno Kammandel, at Geisa, in Thuringia. The little town of Geisa has running through it a stream, the Ulster, which has a heavy fall. Below the town there is a mill-race, which used to be utilised for driving a flour-mill. On a hill directly opposite the mill-race is situated the cork factory of Herr Cuno Kammandel. Formerly steam power was used here to the extent of 20 h.p. Owing to coal having to be carried by carts a distance of three miles the cost of fuel was doubled, and it was consequently decided to employ electric transmission of power from the Ulster. The water power available is employed to drive a turbine made by Messrs. Briegleb, Hansen, and Co., of Gotha. The regulation of the revolutions of the turbine is effected by hand. From the vertical shaft of the turbine horizontal gearing is driven, which actuates by means of pulleys and belts the primary dynamo, which at 700 revolutions per minute has an output of 650 volts and 32 amperes. At full load the dynamo requires 32 h.p. The dynamo is series wound of the four-pole type, and delivers current to a switchboard, where, in addition to a double-pole main switch, there are an ammeter, a rheostat with 16 contact-pieces, and an automatic short-circuiting switch. The rheostat, which is inserted parallel with the field-magnet winding, permits of the strengthening or weakening of the field of the generator, and so controls the number of revolutions of the electromotor, which receives current at more or less pressure. The automatic short-circuiter is a safety apparatus which, in the event of the primary machine being overloaded, short-circuits it. The current is led to the secondary station by copper wire of five millimetres diameter, the wire being supported on 15 telegraph posts. The distance is about 2,200ft. Porcelain insulators of the telephone type are used. Each conductor is protected at both ends by lightning conductors. The leads pass in their course over a governmental telegraph line, and are carried 3ft. above the same. The electromotor at 650 revolutions per minute yields about 600 volts and 24 h.p., and this is the sole motor in the factory. It operates by means of a belt on the main shaft, which works the various machines required, and also the pumps which supply water to the works from the mill-race. The installation has, with a loss on the conductors of 50 volts, a total efficiency of 75 per cent. from the shaft of the dynamo to that of the motor.

Another installation is to be found at the dyeworks of Herr Louis Hermsdorf, at Chemnitz. Instead of using the water from the town supply for the requirements of the works, it is drawn from the River Chemnitz, a rotary pump being employed for the purpose. This is driven at 1,000 revolutions by an electromotor of 10 h.p. The generator is situated at a branch works 1,000ft. distant; at 1,000 revolutions per minute it yields 30 amperes and 300 volts, and is of 14 h.p. This dynamo is driven by steam power. The arrangements are the same as in the Geisa installation. The conductors employed are four millimetres in diameter, and are supported by eight posts.

A third installation has been carried out at the dyeworks of Herr Oswald Sattler, at Meerane, Saxony. The object of the installation is to supply the works with water. The distance the water has to be brought is about 4,700ft., and 3 h.p. is required for the purpose. The primary machine is driven from a steam engine. It is a two-pole dynamo, giving 300 volts and 11 amperes and 5½ h.p. at 1,275 revolutions per minute. The conductors are carried through the streets over the telephone conductors. Insulated copper wire is used at the crossing points. The conductors elsewhere are bare copper wire, and are carried on 33 wooden posts. The electromotor yields 270 volts and 3 h.p. at 1,400 revolutions per minute. The installation has worked satisfactorily for five hours per day since it was put up.

A fourth series transmission plant is to be found at the Saxon Brassworks at Rodewisch. At the primary station there is a turbine of 55 h.p., which drives by belt a four-pole series dynamo of 500 volts and 70 amperes and 53 h.p. at 600 revolutions per minute. The conductors are carried on double-bell insulators on 40ft. poles—the diameter of the wire being 10mm. The poles are about 200ft. apart. At the rolling-works there is a series electromotor of 450 volts and 41 h.p. running at 600 revolutions per minute.

THE USE OF SMALL ARC LAMPS.

The question of introducing small arc lamps is being discussed in the columns of the New York *Electrical Engineer*, with special reference to an editorial published in that journal on March 14. Mr. W. S. Barstow says that he has not settled in his own mind whether arc lamps will be introduced from 50 c.p. upwards, and that a lamp requiring 125 watts has proved itself in Brooklyn a somewhat doubtful success due to the cost of trimming. Arc lamps of 200 watts are, however, a commercial success in that town.

Prof. Elihu Thomson, writing in the same journal says: The application of arc lamps on constant-potential circuits, such as are used for incandescent lighting, naturally raises the question whether quite small arcs or arcs of very limited candle-power may not become available at some time in the near future. As far back as 1882 and 1883 the writer experimented with arcs using as low as two to three amperes, and with a potential between the carbons of about 50 volts. An arc with 2½ to three amperes was readily obtained, and the mechanism for feeding accurately the carbon of small diameter was worked out, but the great difficulty at that time was that no carbons could be had pure enough or uniform enough in structure to permit such arcs to be run steadily, and the feeding mechanism was naturally more delicate and costly than that used with larger carbons, while the length of lamp to accommodate such lengths of carbon as would provide for an eight hours' run was so considerable as to render the lamp ill-proportioned. Subsequently there was tried enclosing the carbons, made of short plates, in a chamber of glass with limited air supply or none at all. This gave better results, but the carbons gave out enough impurities to obscure the glass in a moderate time. With very pure carbon the results might have been much better. The actual waste of the carbon was very slow, and with a good arc length the light was quite steady. The great economy of light production in the arc is sufficient of a stimulus to make such efforts to obtain small arcs of reasonably low candle-power, worth the making. Such experiments were convincing as to the need of very pure carbons, a supply of which was not to be obtained. This need still exists, so far as the writer is aware.

Very small arcs, when burned in the air with ordinary carbons, have a woeful tendency to rotation, a motion of the arc which has a very disagreeable effect on the character of the lighting, and practically destroys its utility. The rotation seemed to be regularly performed by the arc in the crater of the positive carbon, casting the main body of light in a rotary manner, or a constantly-changing direction. With a good quality of carbons, arcs using from 160 to 200 watts are perfectly practicable even with the ordinary mechanism for feeding the carbons. It is gratifying to discover a growing appreciation by station-men and others of the fact that the best results in arc lighting are dependent on the use of the finer varieties of carbon instead of the less perfect, though cheap, carbons so commonly employed. Even the low-price carbons of to-day are, however, in quality very far ahead of the only available carbons of the pioneer days, for which a good round price had to be paid. In fact, really fair carbons were a rarity in the years between 1879 and 1883, and many a plant was subject to condemnation when everything was right except the carbons available for use with it. In fact, those who enter arc work to-day can never obtain an appreciation of the difficulties which were encountered and had to be overcome in making the arc light a commercial success. There was, of course, an added prejudice against the light itself because it was a white light, or appeared bluish in relation to flames, torches, and such other "hereditary" night lights. It is easy to account

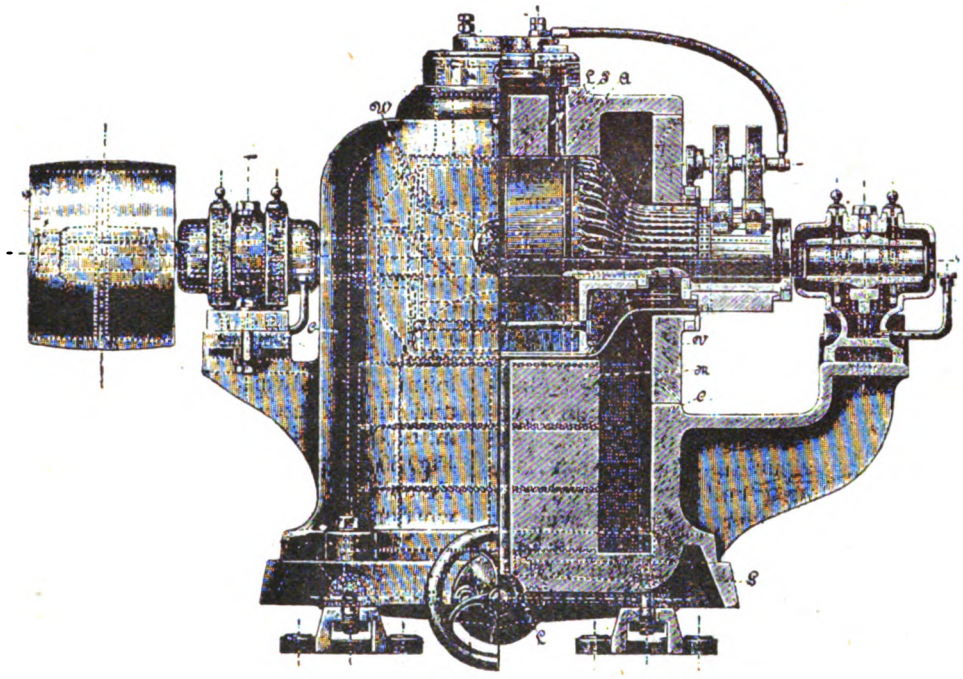
Digitized by Google

for such prejudice, and it is difficult to see how it could have been avoided. For countless ages the human race had relied for night light on fires, torches, lamps burning fats or oils—and the sensorium had come to expect a night light to be orange or yellowish in quality, and to be able to recognise no other to be in correspondence with hereditary expectation. Hence the sudden appearance of a white light at night was a sort of shock which could only be assimilated in the consciousness as something uncanny, inspiring dread or distaste rather than the reverse sentiment. It was called a ghostly light or a ghastly one, and its unsteady flashes and flickers recalled the terrors of the thunderstorm in the night with its bluish and blinding sheets. Burning in full daylight, arc lights have really a yellowish aspect, showing a large proportion of such rays to be present in the arc.

It does not appear that the introduction of small arcs should have any serious effect on the use of incandescents in their legitimate field. It ought, indeed, to have in many instances an opposite effect in somewhat the same way that the introduction of arc lights often led to increased gas consumption, as the standard of sufficiency in illuminating created a demand for more light. When the incandescent lamp was first brought out, predictions were heard that arc lighting would soon become substantially a thing of the past. The writer never felt that any such predictions were likely to be verified, and continued to work assiduously in the arc lighting field, believing thoroughly in its permanence. We may, perhaps, feel equally assured that even if arc lamps of as low power as 50 c.p. became a commercial reality there would still remain a vast field for the extension of lighting by incandescent lamps.

NEW TYPE OF DYNAMO.

A new type of dynamo, which has been designed by Messrs. Pöschmann and Co., of Dresden, is described by Mr. Thom. Marcher in a recent issue of the *Elektrotechnische Zeitschrift*. The illustration shows the principal parts of the dynamo. A round massive magnet core, M, with its coil, is arranged in the centre of a circular bed-plate, G; opposite to this is an upper pole-piece, P, and both are united by means of a closed vertical undivided cylinder, C, closed at the top and bottom. The latter has against the commutator side an opening, which, after the armature, A, has been put into position, is closed by a cover-plate, V. By this arrangement the magnetic distribution is confined to a minimum, sparking is almost entirely avoided, and the amount of copper used is comparatively small. In consequence of the air resistance between the armature and magnet, the magnetic distribution is not entirely removed, as the surrounding air forms a parallel conductor. A small number of lines of force will therefore pass into the air-space and be enclosed by means of the air and the casing without entering the upper pole-piece. There will consequently be a difference in the number of lines of force in the upper and lower poles, which would partly cause downward pressure of the shaft. In order to overcome this, a collar, W, is placed round the upper pole to suck up the lines distributed, and this is suspended in the neutral position. Tests have shown that by this means the armature swings quite free, especially if the shaft is carried in bearings only a fraction of a millimetre out of centre in an upward direction. The machine runs in ball bearings, with double ring lubrication. Ventilation holes, L, are provided in the centre of the magnet core. The air, which is drawn through by means of these and the belt pulley, plays round the armature and passes away from the casing through lateral perforations. It may be mentioned that Prof. Puluj, of Prague, has tested a dynamo of this type capable of energising 200 lamps. The efficiency of the machine at half load was found by the professor to be 91½ per cent., or at full load 93 per cent.



INSTITUTION OF MECHANICAL ENGINEERS.

ADDRESS BY THE PRESIDENT, PROF. ALEXANDER B. W. KENNEDY, LL.D., F.R.S.

(Concluded from page 503.)

I have spoken of possible breakdown of engines or dynamos. There are, of course, other accidents to be provided against. Short of a boiler explosion the most serious of such accidents would doubtless be one occurring to a steam-pipe. The physical consequences of the actual bursting of a steam-pipe are not, of course, the matters at present under consideration. In all probability such an accident would disorganise any station, no matter how well arranged. But short of the actual bursting of a pipe many things happen which may render it necessary to shut down a portion of piping It is generally necessary, therefore, to provide any lighting station with something in the nature of a ring-main system, or its equivalent, by which any engine in the station can be supplied with steam from two directions. In a properly arranged ring-main system it should be possible to disconnect or cut out of use any section of steam-pipe which may be giving trouble without stopping a single engine. Of course, it is not necessary to provide pipes so large that under these conditions there should only be the normal drop of pressure between boilers and engines. One can put up with an extra drop without grumbling if it only occurs under these circumstances. It is inevitable, to reach the required degree of security in this matter, that the steam-pipe should be fitted with a very large number of valves, and these are undoubtedly objectionable if only on account of the very considerable loss by radiation which is almost inevitable from their covers and flanges. But, after all, the making of good steam joints in large pipes at 150lb. pressure is nowadays a very simple matter, and

Digitized by Google

the unavoidable complexity of the arrangement is more than counterbalanced by its usefulness. The duplication of the steam-pipes must obviously extend to the boilers as well as to the engines. The hanging up of a safety-valve, the blowing of a mudhole joint, the bursting of a tube, or any one of half a-dozen other such accidents, may put a boiler suddenly *hors de combat*. It must be possible, therefore, at the shortest notice to cut out any boiler without interfering with the working of the rest. Fortunately, boilers can be forced more readily than engines or dynamos, and such an accident could almost always be met by forcing the remaining boilers somewhat. Reserve in boilers stands thus in the same position as reserve in machines, except in so far that the boilers can be more easily forced, as I have just pointed out. With them, however, as regards security of working, there comes in an even more difficult question than that of reserve—namely, that of readiness for emergencies other than breakdowns. Even in London, where a fog may cause the load on a station to increase ten times in as many minutes, there is

DIAGRAM 1.—This diagram corresponds to the output at the Davies-street Station of the Westminster Electric Supply Corporation during 1893. The great excess in the last quarter over the first quarter is to a considerable extent due to the larger number of lamps which were on circuit towards the end than at the beginning of the year. The great drop in the last week of all is due to the fact that that week included Christmas Day and Boxing Day, as well as a Saturday and Sunday.

practically no difficulty in getting the engines started quickly enough. It is otherwise with the boilers, which, although so easily forced when actually in work, are terribly sluggish in getting up steam as compared with the rapidity with which unexpected darkness used to come over London, and doubtless will come over again when the sun has recovered from its present attempt to outshine all artificial lights. At the most inconvenient time for a breakdown—namely, the time of full load—the engineer knows at least that an engine or dynamo accident can hardly affect him to more than 15 or 20 per cent. of his whole work, of which at the worst a considerable portion can in most cases be taken up by the remaining plant. But the most inconvenient time for a fog to come on is at light load, and then the increase coming

on in a few minutes may be anything from 500 to 1,000 per cent.! And the engineer must be able to meet this in June as much as in December, and with even less notice. Practically, this means that even in summer enough boilers must be kept under steam—if not at full pressure, at something near it—to be able to take up this enormous increase of load in 10 minutes, as soon as ever their fires are brought forward and their dampers opened. (I am speaking here of such cities as London, or Manchester, or Glasgow. Of course, I know that there are happy places, like Rome or Aberdeen, where fogs are unknown, and where, therefore, all this provision against them is unnecessary.) I need hardly point out to you, after going over all these points, that it is improbable that the fuel consumption per indicated horse-power hour in electric light stations will ever reach, or can ever reach, anything like so low a figure as has often been reached in first-class steamers, where the engines and boilers work on continuously day and night at pretty much their most economical load. I will mention just one more point as to security of working in a station—the feed arrangements. Here in London I have several times run considerable risk of stoppage from this cause. A duplication of feed pumps and pipes is an obvious precaution, and one that probably everyone adopts. But few of us can keep water stored in sufficient quantity to last for more than three or four hours at full load, so that without special arrangements we are liable to be extremely inconvenienced by any accident happening to the mains of the water companies outside, which may compel them, on short notice or even no notice at all, to cut off the supply for a few hours. The best arrangements to meet this contingency vary in different places, but the engineer must not lose sight of the fact that the difficulty is one which may occur at any time, and from causes altogether beyond his control and even knowledge.

Outside the station the question of security comes in in connection with the mains. To a certain extent every station which uses either high or low tension feeders has some reserve in their very

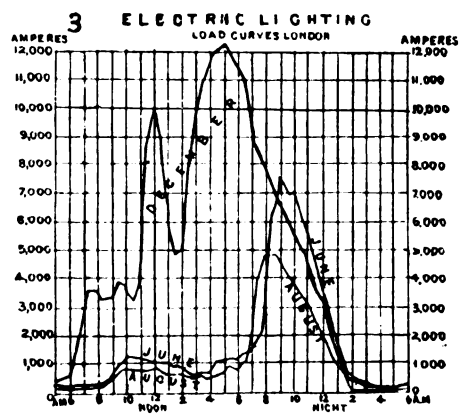

DIAGRAM 3.

number. When a company has more than one station, trunk mains led from one to the other are also a considerable security, as well as a great help to economy. Mr. Frank Bailey, of the Metropolitan Electric Light Company, has carried out a most excellent ring or looped main system on his high-tension distributors, by which he can make sure that any consumers can be supplied two different ways round the circuit, so that any accident to the mains may cause a minimum of inconvenience to a minimum number of consumers. In ordinary low-tension distributing networks the same result should be aimed at, although it cannot generally be obtained in what the mathematicians would call so "elegant" a manner. Many points occur in connection with the arrangement of electric mains which might be discussed in this connection as to the means for isolating and testing them, the desirability of putting large sections into parallel, or working them separately, etc., but these matters rather lie on the electrical than on the mechanical side of the subject, and I must abstain from discussing them here.

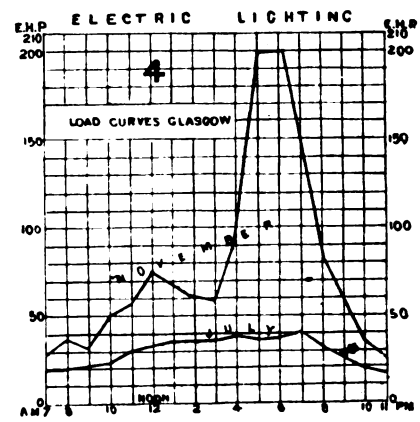

DIAGRAM 4.

I have next to speak of the regulation of an electric lighting station, as forming, along with its security, the two matters which chiefly affect the consumer of electrical energy. All that the consumer cares about is that the pressure in his house should be steady to the eye, and should be not less than its nominal value, and not very greatly above it. In all stations working on a large scale this constancy of pressure in the consumers' houses necessitates a constantly varying pressure at the station in order to make up for the loss of pressure in the mains, which is itself—wholly or in part, according to the system of supply—dependent on the amount of current passing through them. In an ordinary alternating-current station the pressure at times of maximum load exceeds that at times of minimum load by about 5 or 6 per cent. In an alternating-current station with low-tension distributors the excess may be about 12 or 15 per cent. In an ordinary low-tension station with three-wire system it may often be 20 per cent. The actual figure, of course, depends on the current density

Digitized by Google

permitted in the copper; but the figures I have given illustrate the sort of percentage which different engineers have found it advantageous to adopt on a large scale. The primary requisite for proper regulation is obviously enough that the engineer shall know the actual value at each instant of the pressure which he desires to keep steady. In every case where low-tension distributing mains are used this pressure is the pressure at certain feeding points or at certain sub-stations, and it is best known at the central station by direct indication—bringing back pilot wires or potential leads from such points direct to the station, and connecting them to suitable voltmeters there. In these cases the regulation consists in so running the machines that the pressure indicated by these voltmeters is always kept at the desired amount. What appears to me a less satisfactory method is sometimes adopted—namely, the determination by calculation or by experiment of the loss of pressure corresponding to each output, adding this loss to the normal pressure, and regulating the dynamos to the corresponding sum, transformed if necessary. Apart from the fact that in this case the pressure actually received by the consumer is only estimated and not really measured, so that the thing measured is not the really important quantity, there is the additional drawback that the regulation is to a varying quantity instead of to a constant one, and is therefore less likely to be thoroughly satisfactory. In cases where distribution is by high tension with isolated transformers there is, of course, no direct means for keeping the pressure constant in the consumers' premises. If the distance between the nearest and the furthest consumer on any circuit is much less than the distance from the station to the nearest consumer, there may be a reasonably good regulation by the indirect means I have just described. In the case where the distance from the station to the nearest consumer is small in proportion to the distance from the nearest to the furthest, no such regulation is practically possible, and, in fact, in these cases the section of the copper must be made so large as to reduce the drop of pressure within negligible limits. By one or other of the methods which I have mentioned, and preferably, no doubt, by the use of pilot lines, the engineer in the station knows to what pressure he is to work. In every case the station must work at a varying pressure, although in some instances the variation may not be great. The highest pressure must occur always at the times of greatest load. Several means are at the disposal of the engineer for varying this pressure. Best of all I think, as being most convenient and most easily controlled, is the provision of sufficient additional resistance in the fields of the dynamos or exciters to enable the magnetic field to be altered by the mere moving of a switch having many contacts. Of course, to a certain extent this method wastes energy, but the quantity so wasted is so very small in proportion to the whole that it is not too high a price to pay. The switches can be placed upon the switch gallery so that the whole of the regulation may be done by the man in charge there, and be quite removed from the actual control of the engine-drivers. In order that this method may be satisfactorily carried out, the engines must be so arranged that they can be run entirely upon their governors, the stop-valves being opened fully as soon as the machines have taken up any load. In this connection it is worth while noticing that for continuous-current machines constancy of speed—which is, of course, to be distinguished from steadiness of speed, quite a different matter—is not in itself in the least a thing to be insisted on. The governor must be so set as entirely to prevent the engine racing in the case of a sudden short-circuit or other breakdown. But apart from this, an alteration of 5 per cent. or more is not a matter of the least moment. In fact, for practical purposes it is generally better that the governor should not be too finely set. Of course it may quite well happen that in the case of any one engine it may have to run throughout nearly its whole range of power at the same electrical pressure. If, therefore, the governor is so arranged as to allow of a drop in speed at full load, the field resistance must be so proportioned that, notwithstanding this drop, it can either keep the pressure constant or allow it to be increased within the desired limits. A much less satisfactory method of regulation is by means of the stop-valve—that is to say, by the engine-driver actually opening or closing his main steam-valve according to the pressure required. If this has to be done, each engine-driver must be able to see the pressure to which he has to regulate, and instead of regulation taking place by an easily moved switch in the hand of one man, it has to be carried out by the action of half-a-dozen stop-valves in the hands of perhaps as many different men. The enormous voltmeters which were made a few years ago, and I believe are still used in America in some places, having faces so large that they can be seen all over an engine-room, were designed in connection with this particular method of regulation. Regulation by field resistance was perhaps then not so well understood as it is now. At any rate, there can be no doubt which method is the better on all practical grounds. I have been speaking of efficiency of regulation so far as it affects or is affected by the gradual alterations of load such as are represented upon the diagrams on the wall. At times of full load this is practically the only matter of importance, because at such times any sudden increase or decrease of load are small proportionately to the whole load of the station. But in a station where the load every afternoon is, say, 1,000 kilowatts, it may quite well happen that in the early hours of the morning or during a bright forenoon the total load is little more than a hundredth part of this. In such a case the sudden throwing on or off of a motor without proper starting resistance, or even of a photographer's arc lamp under similar conditions, may increase or decrease the actual output by 20 or 30 per cent., or even more. Such variations are most often excessively sudden and of extremely short duration, so that they are particularly difficult to regulate for, and one must only be thankful that in the nature of things they can only occur at times when a little flickering of the light is not noticeable. In stations which are able to use batteries, there is no doubt that the battery acts practically the part of a flywheel in respect to these rapid variations.

I now come to my last section—namely, that of economy of working a station, still looking at the matter, of course, from the point of view of the mechanical engineer. Economy of working covers two sets of questions. There is, first, the reduction of direct cost of coal, oil, stores, water, and maintenance per unit or per horse-power hour; and, secondly, the obtaining of the greatest possible ratio between the net useful and the gross indicated horse-power. Taking these matters in their order, the question of coal naturally comes first. In an electric light station the cost of coal averages not far from four-tenths of the total working expenses. While, however, this matter is so important a one, it is yet one on which so much has been said and written that it need not detain us long. There is no one type of boiler, at least I do not know of any, which is better than all others under the conditions of an electric light station. Indeed, I would go so far as to say that from the point of view of economy there are five or six types of boiler which with equally good stoking will yield equally good and in every respect first-class results. Of course, any type of boiler may be badly arranged or badly proportioned, may be underworked or overworked; but if an engineer is not capable of so proportioning the boilers of whatever type he adopts as to give thoroughly good results, or of finding out whether his results can be improved, he had better at once take to some business which is less complicated than that of scheming an electric light station. It may no doubt sometimes be necessary in order to get a specially large output out of a boiler to provide it with one of the thousand infallible nostrums for that purpose. So far as my own experience has gone, however, I think that almost anything can be done with a really well-designed boiler, if only the engineer in charge knows how to handle his dampers and how to deal with his particular fuel under the conditions where coaxing is required. I have lately had some remarkable illustrations of the way in which a particular boiler could have its output increased 60 per cent. by the application of certain particular apparatus to it, and an exactly similar boiler could then, when the stoker had found out how to manage his fires, give exactly the same increase in output without any change being made in it whatever.

One thing which tells very much against the economy of an electric light station in respect to its evaporation per pound of fuel is the extent to which, during all day in many places, fires must be kept alight and pressures up in boilers capable of giving eight or ten times the actual output, and the extent to which in all stations fuel must be expended in getting boilers ready for the heavy load which comes on only once in 24 hours. These stand-by losses are not, as one would think, losses which get less as the output of the station increases, for the proportion which the stand-by boilers will bear to the actually used boilers at any moment will be practically constant whatever the output of the station. I have found that the total stand-by losses can be reduced in some cases to under 8 per cent. of the total fuel. Below this I have not yet succeeded in coming, although I hope a lower ratio will be obtained in the future. I am afraid it is often considerably more than 10 per cent. I believe that a far larger proportion of fuel waste in a station occurs through causes beyond the boilers than in the boilers themselves—that is to say, it is much more easy to get a good evaporation per pound of coal than a small consumption of water per indicated horse-power. Of the causes which contribute to this, the first is undoubtedly the very great loss which occurs by condensation in the steam-pipes and by leakage through drains and other valves before ever the steam gets to the engines at all. This is probably much greater in proportion in an electric light station than in most other places, because the requirements of security which I have already discussed necessitate the use of a very elaborate system of steam pipes, much more elaborate than is found in any other works. Not only does this system of steam pipes present a large radiating surface, and in various ways offer particular facilities for cooling the steam, but also the absolute necessity of keeping the pipes clear of water at all times, so that any section of them can be used safely at a moment's notice, involves the use of drain pipes and cocks. These necessary adjuncts to a system of steam-pipes, along with the apparatus which we call by courtesy steam-traps and use in connection with them, are a continual source of waste and annoyance to the engineer. The drain cocks get left open, or if they are shut they leak themselves open, the steam-traps require more looking after than the whole of the rest of the machinery put together, and altogether the whole system of pipes, drains, and traps probably cost us in many cases 10 per cent. of our whole fuel. In some experiments which I recently had made I have found the proportion to be 8·8 per cent., and I have reason to think that it is often far greater. I know of no heroic remedy which can be applied to the matter. Probably we have not in general paid sufficient attention to the proper covering of the pipes, including their flanges, and the flanges of the stop-valves. Certainly we have not somehow succeeded in obtaining steam-traps which will really work with any approach to permanent satisfaction under the trying conditions of every-day work. I hope that the use of superheated steam may be found very largely to reduce this particular cause of waste. Apart from this matter, I know no reason why any engine in an electric light station should not work every day and every hour at exactly the economy which the same engine reached on special trials made at the same load under the strict conditions of a specification. I have, in fact, on many occasions compared the running of engines in this way with the running of the same machines at the same loads on their original tests. When I have

Digitized by Google

subtracted the amount of steam used for the feed pumps, the difference was never greater than I have found to be covered by the condensation losses which I have mentioned. Of course it is necessary to remember that engines working in a central station at very varying powers cannot be expected to give average results equal to those obtained at full power on trial. The results should be compared on the basis of tests at corresponding powers, and in order that this comparison may be carried out I always have a series of graduated tests made before taking over machinery.

After the cost of coal comes the cost of oil, water, and stores. These three items together cost in the average about one-fifth as much as the cost of coal alone. There is not much which can be said in circumstances like the present on the question of economy in this part of the expenditure, which really depends altogether on the good management of the engineer in charge. Such matters as the filtering and reusing of lubricants, and as the prevention of all needless waste of water, are obviously to be considered. It is perhaps generally sufficient for the engineer to find out the very lowest cost under these heads obtained in any other station, and to believe he can do a little better if only he tries hard enough. Cost of repairs and maintenance, still more than that of oil and stores, is one about which little can be formulated. There is no one type of engine or dynamo, so far as I know, that can be definitely said to be ahead of all others in respect of the fewness of its repairs. There are several types of machine which in the hands of careful engineers certainly give very good results, although it is somewhat difficult to compare the published figures under this head on account of the number of electrical stations which are still wholly or partially in the hands of their contractors, and in which therefore the full amount of repairs does not appear in the accounts.

I have mentioned that the economy of a station depends on two sets of considerations—namely, the actual quantity of fuel, stores, etc., per indicated horse-power hour, and, secondly, on the actual relation between the useful power and the gross power. It is obvious that it would be of no use to save 10 per cent. on the coal per indicated horse-power hour if that saving involved the use of machinery whose mechanical efficiency was 10 per cent. lower than it would otherwise be. This brings us face to face with the question which is always one of the most important to the engineer—namely, when he has got his horse-power in his engine as cheaply as possible, how to arrange so as to utilise the largest possible proportion of the horse-power thus obtained. The utilised horse-power is represented, in the case of an electric light station, by the energy passing through consumers' meters and paid for by them. Between this useful horse-power and the indicated horse-power of the engine there comes, first, the loss in the engine itself; then the loss between the engine and dynamo; thirdly, the loss in the dynamo itself; and, fourthly, all the losses between the terminals of the dynamo and the consumer's meter. As to loss in the engine itself, this does not appear to vary very much in different types of engine of first-class make. Approximately, it may be taken as about 10 per cent., sometimes a little less, of the full power of the engine, and as remaining very nearly constant at all powers as long as the speed is constant. Thus the mechanical efficiency of an engine which is 90 per cent. at full load, will be only about 80 per cent at half load. The efficiency of a dynamo at full load is much higher—it may be as much as 95 per cent., and may be still 90 per cent., far below half load. Thus the ratio of electrical to indicated horse power of a first-class steam-engine and dynamo may be 85 per cent. at full load, and something like 76 per cent. at half load. This assumes that the engine drives the dynamo direct, and that there is therefore no loss in transmission between them. I must confess that it remains a complete puzzle to me—a puzzle of which I have never found any solution—why engineers should wish, in addition to these practically unavoidable losses, to spend certainly 5 per cent., and on the average probably much more, of the whole of the power in their station in moving ropes or leather belts which have nothing whatever to do with the ultimate result, and which take up an enormous amount of space. The true solution of the matter really appears to me beyond all doubt to be either the use of quick-running engines, as is so common in this country, or of slow-running dynamos, as is so commonly the case on the Continent. I am, of course, here speaking of driving by steam-engines, not by gas-engines, in which latter case a number of other considerations come in. As most steam-engines take practically the same power per revolution to drive themselves, it is obvious that at low powers an increase of mechanical efficiency will be obtained by running at a less speed than that used for full power. This, of course, requires a specially arranged adjustable governor and a wide range of control in the field regulation. But I think it is worth doing in many cases The losses between the dynamo terminals and the consumers' lamps are, in a low-tension system, simply the losses in the leads. In a high-tension system they cover the losses—in general very much smaller—in the leads, but also those in the transformers as well. This is not a place nor a time for entering on a discussion of the relative merits of high and low tension systems—a matter which to anyone who is not a partisan of one or the other could certainly not be adequately discussed in any time short of the whole of that which has been occupied by this paper. Moreover, I need hardly point out that the choice of a system cannot possibly rest upon any one single point, such as the relative magnitude of the losses from a single cause. At present, so far as the figures to which I have access go, it may be interesting to you if I mention that in the case of a low-tension system where the maximum proportion of loss in the feeders is allowed to reach 20 per cent., or thereabouts, the actual average loss of energy throughout the whole year amounts to about 10 per cent. This is, of course, entirely due to ohmic resistance of the feeders themselves and of the network. I have no statistics by which I can compare feeder losses only in an alternating-current system with the figure I have just mentioned, but so far as those figures go to which I have access apparently the total losses both in mains and transformers in a high-tension system are not less than 25 per cent. of the energy generated. It is probable—indeed, I think it is certain—that this figure will be considerably reduced in the cases where banked transformers are employed with low-tension distributing mains. I hardly think, however, that it can be expected that the total losses will ever be so low as with a low-tension system.

5

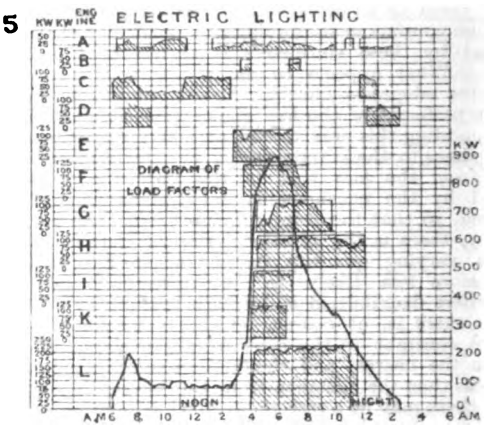

DIAGRAM 5.

I have already alluded to the extent to which the economy of a station is affected by the average load at which its units are run. To attain the greatest economy, it is obviously advisable that the machines actually at work at any moment should all be as nearly as possible fully loaded. The extent to which this can be actually reached in practice is shown in Diagrams 5 and 6. In one of these cases it will be seen that the average load during 24 hours is 78 per cent. of the load which would have been reached if the same machines had run the same number of hours each at its full power. In the other case the percentage is 58. What this particular percentage may be always depends on the exact relations between the load and the size of the units, and therefore in any station may vary very greatly at different times of the year. It is, however, not at all as easy as has often been thought to make the load-factor, to use the expression in the sense of the above ratio, very high. I find it difficult enough in many cases, even with the use of comparatively numerous units, to keep it up to an average even of 65 per cent. Of course it has to be remembered that, whether or not it is economical, the station engineer has to make certain that he has sufficient plant running to take up the work as it comes on. It is much the less of two evils that he should have every engine running every day half an hour before it is wanted, than that once a year he should be just too late with one or two of his machines. When the system of transformer sub-stations comes to be worked out practically a little more than it is at present, I believe that this load-factor problem will be found to be there even more troublesome than it is in the engine-room, and that the capacity of the transformers which the engineer will consider it necessary to keep on circuit in order that he may be always safe against breakdown of any of them, will be considerably greater than has been often assumed.

6

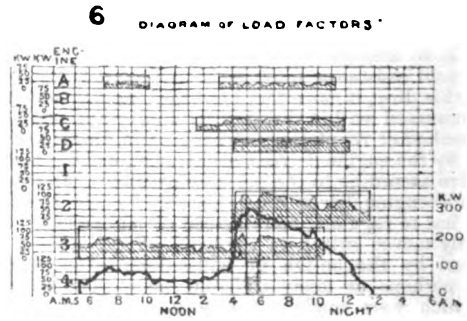

DIAGRAM 6.

I would only, in conclusion, mention one other matter. The mechanical engineer may be supposed to be of all others one who will most naturally take to the making of measurements of all kinds. Any passion which he may have for this has ample scope in connection with electrical work. Electrical measurements, at least with continuous currents, can be made more easily with simpler apparatus and more accurately than any other such measurements. I do not doubt that this fact has helped very much in the extremely rapid progress made during the last few years in matters electrical. Apart altogether from the more refined measurements which should be made from time to time for special purposes, there is no difficulty in getting continuous measurements, self-registered, with an average error of not more than 1 per cent. of the current sent out from each dynamo in a station. The average station volts can also be easily obtained with fair accuracy, and the amount of electrical energy developed

Digitized by Google

at the dynamo terminals can thus be continuously measured as no other similar amount ever has been measured. This amount has to be compared with the amount of energy actually paid for—that is, with the sum of the readings on the meters of consumers. Some of the electrical companies have published with their annual reports detailed electrical balance sheets which show how very small the unaccounted for quantity now is. In the case of the Westminster Electric Supply Corporation it was over 5 per cent. in 1891, 3·16 per cent. in 1892, and was still further reduced to 1 28 per cent. in 1893. Unfortunately, with alternating currents measurements are very much more difficult and troublesome, and, consciously or unconsciously, I think this fact has, to a certain extent, hindered their adoption. There are now, however, alternate-current watt-meters practically free from error due to circuit induction, and capable of giving results with quite sufficient accuracy under the actual conditions of station practice. I believe that very great improvements in the economy of alternate-current working will date in every case from the time when the station commences to make accurate determinations, based on something different from the engine-driver's hourly entries in a log, of the true energy generated and the way in which it has been expended. I am sufficiently conscious of my own weaknesses to know that it is very dangerous for me to touch on the subject of measurements, especially at the very end of an address which has extended to so great a length as this. I will not, however, yield to the temptation, but will be content with simply having mentioned the matter. And, in conclusion, I will only say further that I hope the active electrical engineers among our members will forgive me for having spent an hour on such a very plain statement of matters familiar to them, if I have by this means been able to place before our non-electrical members some intelligible account of the problems at which we are working, looked at from their own point of view.

THE ROYAL SOCIETY'S CONVERSAZIONE.

The first conversazione of the season given by the Royal Society took place on Wednesday evening in the society's rooms at Burlington House, when the president, Lord Kelvin, received a large number of guests. There were, as usual, exhibits illustrating recent advances in almost every department of science. Chemistry alone was neglected, practically the only exhibit being that of Dr. J. H. Gladstone, who brought a number of bottles containing soluble and insoluble varieties of guncotton made 47 years ago. Electrical novelties were scarcely so well represented as last year. Sir David Salomons showed a series of beautiful experiments with vacuum tubes, and Mr. J. Wimshurst brought a model to illustrate his method of overcoming by means of induction the difficulty of carrying an electric cable on board an anchored and freely-swinging lightship. Perhaps the most remarkable of the purely scientific exhibits was the magnetarium devised by Mr. Henry Wylde, in appearance an ordinary geographical globe, but endowed with the same magnetic properties as the earth itself, so that a magnetic needle swung at any point on the surface showed the same dip and declination as it would on the surface of the earth. When the apparatus is set in motion the changes of dip and variation which have been observed since the sixteenth century are accurately reproduced on a small scale. This is brought about by an ingenious distribution of electric currents, one set flowing through insulated coils on the under surface of the thin shell of the visible globe, and another set through similar coils on the outside of a slightly smaller sphere arranged inside the first, and caused to rotate with its equator in the plane of the ecliptic of the outer globe. Prof. Silvanus Thompson performed by means of polyphase electric currents and rotary magnetic fields a number of experiments involving some of the darkest phenomena of molecular physics. Mr. R. E. Crompton, Prof. Moissan, and Mr. E. H. Griffiths had exhibits of appliances for turning electricity to practical use in the production of high temperatures in furnaces and in recording the degree of heat. Prof. Roberts-Austen also exhibited a thermo-electric pyrometer, which by recording variations of temperature in ink on a band of paper has revealed some hitherto unsuspected facts of much industrial importance as regards blast furnaces. Physical science, strictly so called, and its applications to mechanics were illustrated with more than usual detail. Mr. Eric S. Bruce showed some remarkable effects of the persistence of vision by projecting lantern views on a screen formed of a single lath revolving so rapidly as to assume the appearance of a transparent disc. The theory of magic mirrors was explained in the lecture-room, with illustrations projected on the screen, by Mr. J. W. Kearton, who showed how inequalities in a surface which had, subsequently to their formation, been so finely ground that the eye could not detect any break on the polished mirror flashed out in strong relief when a beam of electric light was reflected from it. The Japanese magic mirror, he explained, was produced as a "by-product" in grinding a piece of metal, on the lower surface of which a device had been cast in relief. Mr. A. E. Tutton demonstrated a new method of experimenting with pure monochromatic light of any wave-length, which was procured by means of a spectroscope provided with a second slit instead of an eye-piece, enabling a narrow strip of light to be selected from any part of the spectrum. Among the more purely mechanical contrivances of general interest was one in which Mr. Alley adapts the well-known transmission of force through a row of marbles to the purpose of ship's telegraphs and the opening or closing of engine valves. A mechanical pump for producing high vacua without the use of mercury, shown by Mr. H. A. Fleuss, attracted a good deal of attention; but a more popular exhibit was Mr. W. W. Beaumont's vibromotor, by means of which the energy which in most machinery is expended in producing vibrations may be diverted to do useful work and enable the machinery to run smoothly.—*The Times.*

LEGAL INTELLIGENCE.

WISE AND OTHERS v. THE METROPOLITAN ELECTRIC SUPPLY COMPANY, LIMITED.

The hearing of this case, which was commenced last sittings, was continued and concluded last week before Mr. Justice Stirling in the Chancery Division of the High Court of Justice. The action was brought by several leaseholders and occupiers of houses in Manchester-street, Manchester-square, asking for an injunction to restrain the defendants from using the works erected by them in Marylebone so as to create a nuisances or annoyance to the plaintiffs by noise and vibration, or by smoke, smuts, or grit given off by their fires. The plaintiffs complained that the vibration caused by the engines used to generate the electric current was so great as to cause the houses in the vicinity to tremble and all the doors and windows to rattle in such a manner as to seriously interfere with the comfort and enjoyment of persons living in the houses. Some of the plaintiffs are lodging-house keepers, and gave evidence to the effect that their respective businesses had been seriously affected by the nuisance, people who had been in the habit of taking rooms in their houses being compelled to leave and go elsewhere. Some of the witnesses described the effect of the vibrations as being similar to a slight continuous earthquake, while the rattling of the windows was like the beating of a kettle-drum. Others spoke to the difficulty of obtaining sleep and consequent injury to health. **Prof. Silvanus Thompson**, who had taken various observations as to the cause and effect of the vibration, was among the witnesses for the plaintiffs on Thursday last week. According to his view it arose partly from the fact that the electric works were built upon a site which formed part of the bed of the old River Tyburn, and that the soil was of such a spongy or porous nature that it readily conveyed the vibration caused by the engines. In the course of his experiments as to the effect upon the houses he had constructed an instrument for testing the strength and continuity of the vibrations. The instrument was produced in court, and by means of a phonograph his Lordship was enabled to hear the exact result of the experiment. The defendant company alleged that they had taken the best possible advice and adopted what means they could to mitigate the nuisance. They had since the erection of the machinery caused it to be supported upon solid shafts of masonry going down right through the spongy stratum into a more solid foundation, but, according to the plaintiffs' evidence, neither this course nor any other that had yet been adopted had put an end to the vibration.

Mr. Graham Hastings, Q.C., and Mr. Beaumont appeared for the plaintiffs, and Sir R. Webster, Q.C., Mr. Beale, Q.C., and Mr. Vernon Smith for the defendants.

Sir R. Webster, in opening the defendants' case, contended that they were not liable to have their works stopped by injunction No doubt the plaintiffs were entitled to compensation; indeed, that was the remedy which was expressly provided by the Acts under which the defendant company derived their powers. The company did not deny the fact of the vibration, but no case was made against them of negligence or want of skill. They derived their powers by virtue of the Electric Lighting Act, 1882, and the provisional order made thereunder which had since been embodied in an Act of 1889. In consequence of the impossibility of foreseeing all the effects of electric lighting operations, provisions were inserted in the Acts to the effect that where a company, in carrying out its powers without negligence, caused special damage they should be liable to pay compensation. The company was under the control of the Board of Trade, and could only establish its works with the sanction of that body and the local authorities, all of which had been obtained. The site had been sanctioned after an enquiry by the Board of Trade, and all the provisions of the Acts had been complied with. This was a case of a statutory undertaking for the supply of electricity which might involve special damage, and yet, subject to the works being properly carried on, such damage was to be met by compensation only. There was an absolute obligation on the company to supply electricity to the district, and, in the absence of negligence, the action for an injunction was not maintainable.

The witnesses for the defence were examined at the conclusion of Sir R. Webster's opening. Their evidence was directed to show that every effort had been made by the company to do away with or minimise the vibration and noise. Both the engineers of the company and Prof. Kennedy, whom the company had consulted, expressed their belief that the remedial measures which were now being taken would ultimately result in the cessation of the vibrations. It appeared from their evidence that, in addition to the vertical shafts of masonry which had been sunk down to a solid foundation and on which the engine bed rested, the company were now putting in a series of diagonal struts, similarly carried through the spongy stratum and embedded in the hard clay below, in order to put a stop to any lateral motion by the machinery, which was now believed to be the cause of the vibration.

At the conclusion of the evidence, **Mr. Beale, Q.C.**, for the defendant company, referred to Mr. Justice Kekewich's decision (which was given in our last issue) in the case of Meux's Brewery

Digitized by Google

Company *versus* the City of London Company. He contended that that did not completely cover the present case. The plaintiffs had not adduced such evidence of interference with health and comfort as to entitle them to maintain an action for nuisance, and certainly not for an injunction.

On the resumption of the hearing on Tuesday, **Mr. Graham Hastings, Q.C.**, was heard in reply upon the whole case.

Mr. Justice Stirling said that this was an action brought by five plaintiffs against the defendant company, and it sought to restrain the company from carrying on their business in such a way as to cause a nuisance to the plaintiffs by three different modes—viz , by vibration, noise and smoke, smuts and grit. The defences put forward by the company were twofold—first, it was said that they did not carry on their business in such a way as to cause an actionable nuisance to the plaintiffs ; and, secondly, that even if they did the only remedy of the plaintiffs was by compensation under Section 17 of the Electric Lighting Act, 1882, and not by way of injunction or damages. With regard to the second of these defences his Lordship considered it unnecessary for him to go into the subject, because it so happened that since the hearing of this action was first commenced the identical question had been raised before Mr. Justice Kekewich in a case decided by him during the present sittings (Meux's Brewery Company *v.* City of London Electric Lighting Company, reported in our last issue). Mr. Justice Kekewich appeared to have fully considered the question, and dealt with all the material points. If a few of the points taken in this case had not been touched upon, his Lordship did not think that, had they been taken before Mr. Justice Kekewich, they would have affected the conclusion at which he had arrived. Under these circumstances it would not be right for him (Mr. Justice Stirling) to enter into the question again. He therefore should proceed upon the basis of the conclusion at which Mr. Justice Kekewich had arrived upon the question of law, and accordingly must start with the assumption that the defendant company was not entitled to carry on its works in such a way as to cause a nuisance to its neighbours. Upon that two questions arose—first, whether, in fact, the nuisance was caused by the works ; and, secondly, what was the remedy of the plaintiffs in respect of it. On the question of what constituted a nuisance his Lordship referred to the case of Walter *v.* Selfe, where V.C. Knight-Bruce defined it as an "inconvenience materially interfering with the ordinary comfort physically of human existence, not merely according to elegant or dainty modes and habits of living, but according to plain and sober and simple notions among the English people." That had been referred to and approved of in many cases, and particularly by Lord Selborne in Fleming *v.* Hislop, where he said, referring to Walter *v.* Selfe, that the case and "all the cases which have followed it have laid down this proposition in substance, and very nearly in words, if I am not mistaken, that what causes material discomfort and annoyance for the ordinary purposes of life to a man's house or to his property is to be restrained, subject, of course, to any question which the circumstances of the particular case may raise, and that although the evidence does not go to the length of proving that health is in danger." His Lordship then referred to the evidence as to the existence of the vibration, and to the means which had been adopted by the defendants to get rid of it, and said that it must be taken upon the evidence that there was, in fact, a substantial amount of vibration in the plaintiffs' houses due to the working of the defendants' engines. Did that in law constitute a nuisance? The test to be applied was that suggested by V.C. Knight-Bruce and adopted by Lord Selborne—viz., did it cause "material discomfort and annoyance for the ordinary purposes of life?" The plaintiffs spoke very forcibly as to the vibration. They also mentioned the fact of noise, but it seemed that the real substantial complaint was as to the vibration. The complaint as to the noise might perhaps be regarded as a kind of appendix to the vibration. His Lordship then further examined the evidence upon the question of the effect of the vibration upon the houses, remarking that one of the most remarkable features of it, as pointed out by the scientific witnesses, was its fitfulness. Sometimes it would be felt more in one room and sometimes in another, now in one house and now in another. But, taking the evidence of the witnesses as honest statements giving a fair account of what was experienced in the houses, his Lordship came to the conclusion that a case was made out of interference with the enjoyment in the ordinary way of these houses. The ordinary occupation of people living in them was interfered with, and there was evidence that the occupants were unable to enjoy their ordinary rest. The evidence had been given with moderation and without exaggeration, though perhaps a little colouring had been introduced ; but a substantial case of nuisance from the vibration had been made out. As to the noise occasioned by the machinery, his Lordship did not come to the same conclusion. It was not a serious matter of complaint. Still less so was the complaint as to smoke. He accepted the statement of the defendants' engineer that during the coal strike inferior coal had to be used, which might have caused some annoyance, but there was no case for an injunction or damages as to either noise or smoke. That, however, was not a serious part of the case, and had not materially increased the costs of the action. It followed that the Court ought to grant an injunction and an enquiry as to damages. That injunction and enquiry, however, would be postponed for a time. The company had been unfortunate, and ever since October, 1892, they had done their very best to remove all ground of complaint. If they had not succeeded, it was no fault of theirs. The case presented an engineering problem which was apparently entirely new and very difficult, and the company ought to have a fair opportunity of completing the remedial works upon which they were still engaged. Having regard to the difficulty of the subject and the uncertainty of the success of the means which could be adopted, it was fair to suspend the injunction for three months. The injunction and enquiry as to damages would be confined to the subject of vibration, and the defendants would not be precluded from applying, if necessary, for a further extension of time. The defendants must pay the costs of the action.

ALDIN v. LATIMER CLARK AND CO.

In this case, which was argued last session, **Mr. Justice Stirling** gave judgment on Tuesday in the Chancery Division of the High Court of Justice. The plaintiff was the lessee of certain premises at Richmond, in Surrey, and by this action he sought to restrain the defendants, who were the owners of adjoining property, upon which they had erected works for the purpose of supplying the town with electric light, from violating in various ways his rights as lessee. The plaintiff derived his title from a Mr. Munro, who was also the predecessor in title of the defendant company. Previously to 1878 Munro carried on business as a stonemason and timber merchant upon the premises now occupied by the plaintiff and the defendants. In April, 1888, he agreed to sell the goodwill of his business of timber merchant to the plaintiff for £1,000, and to grant him a lease of that portion of the property on which that business was carried on. Accordingly, on July 1, 1878, Munro granted the plaintiff a lease of the premises in question with the buildings thereon for 21 years at the yearly rent of £160, with a right of way over a portion of the adjoining property. The lease contained a covenant by the plaintiff to carry on upon the premises throughout the term "the timber trade heretofore carried on by the said John Munro," and Munro covenanted for quiet enjoyment in the usual terms. Under a subsequent agreement the plaintiff, with the consent of Munro, erected an additional shed or building upon the demised property, Munro advancing a portion of the cost and the plaintiff agreeing to pay an additional rent in respect of the shed so erected. Munro remained in occupation of the adjoining property, and carried on there his business of a stone merchant down to his death in 1892. After his death his devisees sold the whole of his property (including that demised to the plaintiff) to the defendant company, who proceeded to erect thereon their electric lighting works. The matters mainly complained of by the plaintiff were the following: (1) interference with the access of air to the drying-sheds used in connection with the timber business; (2) interference with the right of way granted by the lease of July 1, 1878 ; (3) interference with certain ventilators in the plaintiff's stables ; (4) user of the defendants' property so as to heat the plaintiff's stables and render them unhealthy, and so as to endanger the plaintiff's premises and stock-in-trade and cause risk of damage by fire. The chief complaint, however, on the part of the plaintiff was that the works erected by the defendant company injuriously affected the access of air to the drying-sheds so as to render them substantially less useful for the purpose of the timber business which the plaintiff was bound to carry on upon the demised premises, and it was contended on his behalf that the acts of the defendants constituted either a derogation from the grants contained in the lease, or else a violation of the covenants for quiet enjoyment therein contained.

Mr. Graham Hastings, Q.C., and Mr. Ingpen appeared for the plaintiff; and Mr. Finlay, Q.C., Mr. Beale, Q.C., and Mr. Marcy for the defendants.

Mr. Justice Stirling, after stating the facts, said that the legal principle invoked on behalf of the plaintiff appeared to be recognised in several modern cases. Thus in North-Eastern Railway Company *v.* Elliot, a case relating to a right of support, Lord Hatherley (then Vice-Chancellor Wood) said : "If a landowner conveys one of two closes to another he cannot afterwards do anything to derograte from his grant ; and if the conveyance is made for the express purpose of having buildings erected upon the land so granted, a covenant is implied on the part of the grantor to do nothing to prevent the land being used for the purpose for which, to the knowledge of the grantor, the conveyance is made." That was the principle established by Caledonian Railway Company *v.* Sprot, where Lord Cranworth said that if a grant was made expressly to enable the grantee to build his house on the land granted, then there was an implied warrant of support, subjacent and adjacent, as if the house had already existed. In Robinson *v.* Kilvert, a landlord let the floor of a house to a tenant for a paper warehouse, retaining a cellar immediately below. He afterwards commenced a manufacture in the cellar which required the air to be hot and dry, and employed heating apparatus which raised the temperature in the demised portion very considerably, with the result that some kinds of paper warehoused there were injured and made less valuable, though paper generally did not suffer. The landlord was ignorant at the time of the letting that the tenant was going to store any particular kind of paper which was likely to be deteriorated by heat which would not hurt paper generally, and it was held that the landlord was not liable either on the ground of nuisance of derogation from his grant, or breach of the convenant for quiet enjoyment. His Lordship then referred to the judgments of the Court of Appeal in that case, and, continuing, said that the result of those judgments appeared to be that where a landlord demised part of his property for carrying on a particular business he was bound to abstain from doing anything on the remaining portion which would render the demised premises unfit for carrying on such business in the way in which it was ordinarily carried on, but that this obligation did not extend to special branches of

Digitized by Google

the business which called for extraordinary protection. Reference was made in argument to the cases which have arisen as to the right of access of air to buildings. It was laid down in Aldred's case that where there is a grant of windows, then "for stopping as well of the wholesome air as of light an action lies, and damages shall be recovered for them, for both are necessary." In Hall *v.* Lichfield Brewery Company damages were given in respect of an obstruction of air to apertures (in the nature of windows) in a slaughter-house, the right having been gained by user for between 30 and 40 years. Again, it was held in Bass *v.* Gregory that the right to the uninterrupted flow of air through a definite channel over adjoining property could be acquired by user for a sufficient period, and an injunction was granted to restrain interference with it. On the other hand, it was held in Webb *v.* Bird that the owner of a windmill was not entitled to complain of the erection by the defendant of a schoolhouse so as to obstruct the access of currents of air to the mill enjoyed over the defendant's land for upwards of 20 years. His Lordship, after referring to other authorities, said that these cases dealt mainly with the subject of acquisition of the right by user, and not with the rights conferred by deed or grant. The judgments to which he had referred to show that under a grant expressed in general terms, and not made for any specific purpose, the grantee would not acquire a right by way of easement to the access of air, except where such right was enjoyed through a definite aperture in the nature of a window on the property granted, or through a definite channel over adjoining property. On the other hand, his Lordship saw nothing in these cases inconsistent with the principle recognised in Caledonian Railway *v.* Sprot, North-Eastern Railway Company *v.* Elliot, and Robinson *v.* Kilvert, that the grantor of land to be used for a particular purpose is under an obligation to abstain from doing anything on the adjoining property belonging to him which would prevent the land granted from being used for the purpose for which the grant was made. This seemed to accord with the general rule that a grantor may not derogate from his own grant, and to be far more consonant with justice than that contended for by the defendants—viz., that the grantee had no right of action unless the grantor could be proved to be acting maliciously. In the present case the lease was not merely granted for the purpose that the land demised might be used by the plaintiff for carrying on his business as a timber merchant, but it contained an express covenant binding him to carry on that business. In his Lordship's opinion, Munro became subject to the obligation to abstain from doing anything on his adjoining property which would substantially interfere with the carrying on of that business in the ordinary course; and that obligation bound the defendants as assigns from him, subject to the existing lease. His Lordship then proceeded to consider the evidence, and upon it came to the conclusion that some injury to the drying-sheds had been made out, but not sufficient to justify the granting of an injunction. The plaintiff was entitled to an enquiry as to the damages he had sustained by reason of the buildings rendering the sheds less fit for use in the ordinary course of his business as a timber merchant.

MUIRHEAD AND ANOTHER v. THE COMMERCIAL CABLE COMPANY.

On Saturday judgment was given by Mr. Justice Kennedy in the Queen's Bench Division for the plaintiffs in this action, which occupied the Court from February 28 to March 7 last. The plaintiffs, J. and A. Muirhead and H. Arnand Taylor, the patentees and proprietors of certain patents for the system of duplicating cables known as the "Muirhead Duplex System," sued the defendants, a foreign company incorporated under the United States laws, the owners of certain cables connecting North America and Ireland and Ireland and France, to recover royalties under a written agreement, dated January 2, 1884, giving the defendants a license to use certain patents of the plaintiffs in consideration of a yearly payment of £1,250, to be increased in certain eventualities. The sums claimed were £1,879. 18s. 9d. for royalties from July to September, 1891, and £1,685. 2s. 8d. for royalties from September to December, 1891, making in all a sum of £3,566 odd. The defendants admitted the deed of contract, and also a *primâ facie* liability under it. But they alleged that the patents in question had run out at a certain date, and they paid all the royalties due from them up to that date into court. Thus, the defendants undertook the responsibility of proving that the plaintiffs' American patent of 1880 terminated at the same date as their English patent by the law in the United States that enacts that "every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent." In order to establish that contention it was necessary in effect to show that the plaintiffs' American patent of 1880 was substantially identical to their patent of 1876. The plaintiffs pleaded that such a course was not open to the defendants on the doctrine that a licensee cannot attack the validity of the patent for which the license is granted any more than could a lessee attack his landlord's title though he could show that the lease had expired.

Mr. Finlay, Q.C., Mr. Bousfield, and Mr. E. H. Pollard appeared for the plaintiffs; and Sir Richard Webster, Q.C., Mr. F. S. Moulton, Q.C., and Mr. A. J. Walter were for the defendant company; and Mr. Carpmael held a watching brief for an interested third party.

Mr. Findlay, in opening the case for the plaintiffs, said the action practically involved a sum of some £45,000, and he pointed out what were the issues of law and fact, and proceeded to give a description of Muirhead's duplex system of telegraphy. The learned counsel then proceeded to deal with the case from its legal aspect, and contended that, on the authority of Clark *v.* Adie, the defendants as licensees of the American 1880 patent, were estopped from attacking the validity of that patent, which, he argued, they did if they attempted to show that it was anticipated by the 1876 patent. But, even assuming that at law the defendants could go into this question, he submitted that the invention claimed by the plaintiffs in the 1880 patent was for a certain combination of the rheostat, the condensers—one on each arm of the bridge, and another on the bridge itself below the receiving instrument, which combination was, he contended, entirely novel, and the results it gave were of the greatest commercial value. It produced a greater rapidity of transmission and a more perfect balance than had ever before been the case. In judging whether this combination was new or not he submitted that his Lordship should not be guided by the same considerations as would influence him in construing a combination of mechanical movements under ordinary circumstances, but to be guided rather by the results obtained. For all electricians agreed that the electric conditions and surroundings of a submarine cable were so very complicated and intricate that they found it impracticable to sit down and work out in the ordinary way the mathematical formulæ in connection with any set of combinations (in a duplex system) so as to arrive at what would be the definite result. It was found easier to make changes in the system by a variety of practical experiments, and to watch the results. The least little alteration in the exact position of any one of the apparati might produce most different results—results that could not, as he had said, be worked out in a moment by set mathematical formulæ. He hoped, therefore, that the learned judge would not be misled into adopting a view that, because some of the plans or arrangements for duplexing, as shown in the 1876 patent, were somewhat similar to those shown in that of 1880, therefore the two patents were substantially the same. He would ask his Lordship to look at the practical results obtained by each system, and to judge from them as to difference or otherwise.

Prof. Silvanus Thompson, F.R.S., Lord Kelvin, F.R.S., Sir Frederick Bramwell, Mr. George Mockeridge, Mr. John Imray, Mr. Herbert Taylor, Prof. J. T. Bottomley, the Messrs. Muirhead, and Dr. Hopkinson, F.R.S., were all called for the plaintiffs and examined at length upon the scientific aspect of the case and in support of the plaintiffs' points.

Sir R. Webster, for the defence, said there were in it two issues—one of law, the other of fact. His Lordship would have to deal with the American statutes and cases so far as they affected the case and apply them accordingly. For by one of the clauses of the deed of agreement between the defendants and the plaintiffs it was agreed that "all questions arising thereon should be determined by a competent English tribunal as to the jurisdiction of which the parties hereto bind themselves beforehand to submit." There were, he said, three or four authorities of American patent law to the effect that, although upon the grant of an American patent there may be no limit or no reference to the foreign patent, yet the grant came to an end conterminously with the latter if the Court were satisfied that the two inventions in the respective patents were substantially identical, and even in an action for infringement brought against a person who is admitting the validity if the Court is satisfied that the inventions are the same.

Mr. Justice Kennedy said he had looked at the authorities (Canan *v.* Pound Manufacturing Company, 23 Blatchford, 173, and Bate Refrigerating Company *v.* Hammond, 129 U. S. Repts., 151), and he agreed that it was so, and he had understood Mr. Finlay to do the same.

Mr. Finlay said he did, but he submitted that it was not open to the defendants (licensees) to attack the validity of the plaintiffs' 1880 patent.

Sir R. Webster said he did not attack its validity, but it was open to the defendants to show that, the term of, so to speak, the governing patent having expired, they were no longer liable to pay royalties to the plaintiffs. The United States laws allowed an inventor to patent at any time, provided that the invention had not been brought into public use in that country for more than two years before The defendants only argued that by the United States law this 1880 patent came to an end at the same date as that of 1876. The true position of a licensee was clearly defined in Crossley *v.* Dixon and Clark *v.* Adie. As regarded the Canadian patents, he understood that their identity with the 1880 one was now admitted, and he need not discuss them further. Passing on to deal with the scientific part of the case, he said that when all the many technicalities with which the subject had been, perhaps unavoidably, overlaid were put on one side, the issue was a very simple one—viz., aye or no, was the patent of 1880 substantially identical to that of 1876? If he satisfied the Court that it was, then his clients were entitled to judgment on the authority of Siemens *v.* Sellers. It was, he said, a remarkable fact that if this 1880 patent was new and such an improvement as it was now said to be, it should never have been patented by the plaintiffs in England. He would suggest that what really had happened was this, that in 1880 the plaintiffs had discovered that the particular combination—the subject of their 1876 patent—shown in Figs. 2 and 3 of that specification was practically the best of all the combinations therein described, and that that being so they picked it out and claimed it, when they came to describe that part of their 1876 patent which they were anxious to protect in America in 1880. It was a clear case of a patentee patenting in the States that portion of his old English patent which he had found by experience to be the most useful. The only invention which the plaintiffs could claim in their 1876 patent was the placing the

Digitized by Google

condensers in the bridge arms, like their 1880 patent, and it was, he said, a complete afterthought for them now to say that that was not what they had then claimed. He contended that any skilled electrical workman carrying out what was described in the 1876 specification not only could, but must produce substantially identical results as he would if working on that of 1880. He concluded by directing the attention of the Court to the material admission which he had got from the different expert witnesses in favour of his general contention.

Prof Andrew Jamieson, Mr. J. Swinburne, Mr. H. R. Kempe, Mr. John Gott, Mr. Frank Jacob (manager to Messrs. Siemens Bros.), and **Sir H. C. Mance** gave scientific expert evidence in favour of the defendants' contention.

Mr. Moulton summed up the case for the defendants, contending, on the evidence of all the expert witnesses, it was clear that the patent of 1880 was substantially the same as that of 1876. In concluding, he briefly alluded to the legal aspect of the case, saying that his friend Mr. Walter would call his Lordship's attention to the American law on the subject. He agreed with Mr Finlay that the true test, according to the American cases, was not whether the American patent would be an infringement of the foreign patent, but whether the foreign patent would be an infringement of the American patent.

The learned **Judge** pointed out that one of the American judges put it rather differently— viz., that what would infringe the American patent would infringe the English patent; and what would infringe that was made free to the public by the expiration of the English patent.

Mr. Finlay said their contention was that the 1880 patent was for a combination of old elements contained in that of 1876, and that anyone wishing to use the patent of 1880 would have to obtain the license of both patentees.

Mr. Moulton resumed, contending that the true test was whether a person working a patent like the 1876 one would not be infringing that of 1880. He clearly would upon the evidence, and, therefore, by all the American cases and the statute, the 1880 patent must expire on the same date as that of 1876. The defence in no way attacked the validity of the American patent *per se*

Mr. A. Walter argued for the defence (1) that the facts established sufficient identity between the two patents of 1876 and 1880 to make the latter expire at the same date as the former—viz, in 1891—within the principles of American statute and case law, by which the 1880 patent was governed. Secondly, he argued that it was not necessary under Section 4,887 that the American patent of 1880 should be limited on its face so as to be conterminous with that of 1876 in England. He next dealt with the point, made by the defendants, that the 1880 patent was applied for not by the true inventor, John Muirhead, but by Alexander Muirhead, upon a communication to the latter from the former. The learned counsel concluded by directing the Court's attention to the Canadian statutes, so far as they affected that part of the case relating to the plaintiffs' Canadian patents, which were admitted to be identical with the 1880 patent.

Mr. Bousfield then addressed the Court for the plaintiffs, and, reviewing the evidence of fact, contended that the identity of the two patents had not been established, that of 1880 being one for a special and improved combination of certain parts of that of 1876. He referred to the American cases cited by Mr. Walter, but argued that they were all distinguishable from the present case, inasmuch as in all of them the question of identity was clearly established to the Court, which was not, he submitted, the position here.

Mr. Finlay followed upon the law.

Mr. Justice Kennedy, in delivering judgment in favour of the plaintiffs, outlined the nature of the claim, and referred to the written agreement of January 2, 1884, under which the plaintiffs had granted the defendants license to use their patents in connection with duplex telegraphy upon certain terms. The only important part of that agreement for the purpose of deciding the case was, he said, the first article thereof—viz.: "The inventors grant to the company the right to apply this said patented duplex apparatus to the above-named cables. This grant is made for the whole period during which the patents shall last. . . ." The clause further bound the plaintiffs—the inventors—to give to the defendants all the benefits of any improvements which they might make in their then system during the currency of this license. For the purposes of this action, his Lordship said, it might be taken that this agreement was carried out by both parties up to July 1, 1891, and it was the quarterly payments due subsequent to that date down to December 25, 1896, that the plaintiffs now sought to recover. The action had an interest far beyond those amounts, however, for if the plaintiffs were entitled to recover them, it followed that they were entitled to similar quarterly payments for several succeeding years also. The issue which was raised was, Was Mr. Alexander Muirhead's patent, No. 234,490, dated November 16, 1880, a patent which, in the language of the article of the agreement he had referred to, was "lasting" after July 1, 1891? The plaintiffs contended that it was, and if it were not the defendants were entitled to judgment. The determination of that issue involved some important issues of law and some complicated questions of fact of a scientific and highly technical character, the trial of which occupied several days. The plaintiffs' patent of 1880 was granted by the American Patent Office, and was expressed to be for 17 years from November 16, 1880. *Primâ facie*, therefore, it would last until November 16, 1897; but, being a United States patent, it was governed by American law, which enacted that "every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force more than 17 years." Having also referred to Rule 162 (United States Rules of Practice), his Lordship said it had been, in his view, decided by the American cases that, although an American patent had not upon its face been limited, but contained an express grant of the patent rights for the full term of 17 years, nevertheless, by operation of law, if the invention had, in fact, been primarily patented abroad, and the foreign patent had expired before the 17 years' term had run out, the American patent would expire at the same time. It was also settled law that the United States statutes were not to be interpreted as invalidating *ab initio* a patent wherein, although it is for an invention previously patented abroad, the grant was not limited, but was for the full term of 17 years. The statutes were to be construed simply as curtailing the effect or duration of the grant. In other words, the patent is a valid grant, but is good only for the shorter term, and expires at the expiration of the foreign patent of which it is a copy. That being the state of the American law as to patents, the defence to the plaintiffs' claim was that the plaintiffs' American patent of 1886 was for "an invention which had been primarily patented in a foreign country"—viz., the English patent granted to Mr. Muirhead in 1876, No. 2,564 which expired not later than July 1, 1891—and that the American patent, being in substance the same as that of 1876, the former, by operation of American law, terminated on July 1, 1891, though on its face it was expressed to last for 17 years from November 16, 1880. In reply to that the plaintiffs raised two sets of contentions, one purely legal and the other partly legal and partly of fact and based upon the construction of the English and American patents and the inferences to be drawn from the scientific evidence. First, as to the law. The plaintiffs say that, as between a patentee and a party charged with infringing the patent, the alleged infringer may, according to American law, succeed by proving that the American patent has expired because of the expiration of a prior foreign patent granted for the same invention, although the duration of the American patent has not been limited, as it ought to have been, upon its face to the duration of the foreign patent; yet that line of defence is not open to a licensee as against his licensor, because to establish it the licensee had to attack the validity of the patent. The learned Judge held that the plaintiffs' view upon that point was wrong, and that the defendants were not estopped from setting up the defence that the American patent had expired with the English one of 1876, if those patents were the same in substance and effect. He also decided that on the evidence the fair inference was that the patent of 1876 had been granted with Mr. Alexander Muirhead's knowledge and consent, and that the United States law was applicable if it was found, in fact, that the English patent of 1876 anticipated that granted in America in 1880. Lastly, he had been asked to hold that he could not, sitting here, find that the American patent had expired without proof of a decision in the United States Court to that effect. This action was, however, he pointed out, brought upon a written agreement, which expressly provided that it was to be construed as an English contract, and that all questions or disputes arising thereout should be determined by a competent English tribunal. How could it, therefore, he said, be successfully argued that he ought to refuse to try the questions raised in this action between the parties? The learned Judge continued: Having thus dealt with the various legal contentions, he came to the more difficult but most interesting part of the case—viz., were the defendants right in their allegation that the plaintiffs' American patent of 1880 was the same invention as that for which the 1876 patent had been granted them in England? Unless the defendants were right in that the defence to the action entirely failed, and the plaintiffs were entitled to judgment. In dealing with this portion of the case, the learned Judge, after some prefatory remarks upon the highly technical nature of the evidence and the very convenient mode in which the American cases and statutes had been laid before the Court, proceeded to deal with the general principles established in these American cases as applicable to this action, and observed that, as laid down in Brush Electric Company *v.* Julien Electric Company, if there were any doubt upon a question of the identity of an American patent with that of a foreign one the patentee was entitled to the benefit of such doubt, as the policy of the law was to support the patentee's rights. The learned Judge also referred to the case of Siemens *v.* Sellars and Judge Cox's judgment in the Electric Accumulator Company *v.* Julien Electric Company, Limited, upon the questions of infringement and as to the true test of identity in patents, and, continuing, asked—(1) Is the principal invention of the American patent of 1880 found in the English one of 1876? (2) Is the subject-matter of the one the same as that of the other? (3) Could both the patents have been granted in America? (4) Would a person skilled in this art, from reading the description of the English patent of 1876 be able therefrom to construct the apparatus described and claimed in the American patent of 1880? Those questions involved, in his opinion, the principles deducible from all the American cases as to the identity of the patents of 1876 and 1880. The claim of the 1880 patent was one of the narrowest kind, and was for a particular combination only. The elements forming that combination were admittedly old. "My invention," says the patentee, "relates to duplex telegraphs of the class worked on the bridge or differential system." "The object is more especially to reduce the retardation of the signals and increase the speed of transmission of submarine telegraph lines, which ends I attain by certain novel combinations and adjustments of old instrumentalities set out in the claims at the end of this specification." The defendants, in order to succeed, must establish beyond all doubt that this particular combination of old instrumentalities—the working of which undoubtedly, said

Digitized by Google

the learned Judge, produced commercially better results than had ever been obtained before—was to be found in the earlier patent of 1876. Put shortly, the distinctions seemed to him to consist in the method and means of adjustment—that was, the maintaining the proper balance. He was satisfied upon the expert evidence that the introduction of the "three-terminal" rheostat of low resistance placed at the apex of the bridge arms, and therefore in such a position as not merely to afford an easy and sufficient means of varying the resistances so as to get the ratio which gave a balance, but also to maintain the sum of the resistances of the two bridge arms constant, was a very important part of the 1880 combination. Having in some detail described the differences in his judgment, as established by the evidence, between the two patents, the learned judge, in conclusion, said that on all the evidence he was clearly of opinion that the patent of 1876 did not contain the same combination as was found in the American patent of 1880, and that in his opinion the latter was a good and novel patent. There would therefore be judgment for the plaintiffs for £3,566. 1s. 5d., and costs.

Execution was stayed for 21 days to consider the question of an appeal.

On Monday, the question was raised as to whether or not the plaintiffs were entitled to interest at 5 per cent. upon the amount of the royalties which were found to be due to the plaintiffs from the defendants under the agreement of January 2, 1884.

Mr. Walter said that the question involved several points which would require some time to argue, as he was prepared with several cases in point to which he would have to refer. As his Lordship was engaged trying cases with juries, it would be inconvenient to argue the question now; and he would therefore ask his Lordship to fix a day when it would be more convenient.

Mr. Pollard, for the plaintiffs, said that he was quite prepared to argue the points at once, and would not occupy more than six or seven minutes.

Mr. Justice Kennedy said the question involved a considerable sum of money, and he was willing to hear the arguments at any time which counsel might agree upon, either during or after the regular hours for sitting. If, therefore, counsel would agree upon an hour and day and let him know, he would meet them in any way he could.

The matter then dropped.

COMPANIES' MEETINGS.

PHONOPORE COMPANY.

The fifth annual general meeting was held on Monday at Winchester House, E.C., Mr. Henry Seebohm (the chairman) presiding.

The **Chairman**, in moving the adoption of the report and balance-sheet, said that the late Board, when it took over the management of the Company from the previous Board, took it over with a light heart. They thought that all the difficulties had been overcome. Members of the late Board and electrical experts whom they consulted, especially Mr. Spagnoletti, took a very sanguine view of the Company's position. They could, therefore, well imagine that, in the face of such strong evidence in favour of its perfection, it took them a very long time before they were absolutely convinced, as they were now, that what they possessed was little more than a pretty electrical toy. There were great difficulties to be overcome in the practical working of the phonopore. They were, no doubt, in an ideal position, and not in a practical one, and those difficulties were continually developing from day to day, and from week to week correspondence was laid before the Board, with one almost uniform result—namely, everybody was anxious to use the instrument, and all who tried it were very much pleased with it; but by-and-by they found that the adjustment of it was so delicate that it was more than the average telegraphic clerk was capable of grappling with. The Board had, therefore, constantly to send out messengers to put instruments right which, for some reason, had gone wrong. He had no doubt that Mr. Langdon Davies believed every word he uttered, although those statements had not been borne out by facts. The directors now found that when they sent out instruments they were followed by more orders, and that in itself was a satisfactory matter. Those who took the instruments were not grumbling at their imperfections, but at the price. The Company was now sending out people to fix up fresh instruments, and the results from those instruments had been much more satisfactory than they were 12 months ago. The directors had made several important improvements, including a new receiver and a new phonophone sounder, and they were now able to work their instrument upon a single-needle key, as well as on the Morse system. After alluding to the satisfactory report on the alterations and improvement in the instruments made by Prof. Silvanus P Thompson, and circulated amongst the shareholders, the Chairman stated that the directors had tested the phonopore, and were now of opinion that they had got an instrument which would meet the requirements of the market, and they hoped, therefore, that the position of the Company would be better in the future than it had been in the past. There could be no doubt whatever that in order to keep the Company in a proper position fresh capital would have to be raised in some form or other.

Mr. A. W. Hart seconded the motion.

Mr. Langdon Davies moved as an amendment: "That the consideration of the report and accounts for the year 1893 be deferred to an adjourned meeting, to be held within a month, and that a committee of shareholders be appointed to join the Board in considering the report and general condition of the Company's affairs. The directors and the committee to make a joint report or separate reports, as they think fit."

Mr. Philbrick seconded the amendment, and after a long discussion, in the course of which **Prof. S. Thompson**, **Mr. Kesky**, **Mr. Spagnoletti**, and others took part, the amendment was put to the meeting and rejected, and the resolution for the adoption of the report carried by a majority.

INDO-EUROPEAN TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting was held last week at Winchester House, Major-General G. B. Tremenheere presiding.

In moving the adoption of the report and accounts, the **Chairman** said that the Company had had a prosperous year, having realised by way of revenue £5,380 more than in 1892. The expenses, however, had been slightly in excess. After placing £10,000 to reserve the Board recommended the payment of a dividend and bonus of 10 per cent. for the past year, carrying £6,452 forward. The work on the Company's system and on the other lines in connection therewith had been carried on with the most perfect regularity, and the average time of the messages had been eminently satisfactory. As a mark of their appreciation of the services of the staff, the Board had decided to set aside £4,000 for them from revenue by way of bonus, thus celebrating the completion of the first 25 years of the existence of the Company. He thought he might congratulate the proprietors on the very sound position of the Company.

The report was adopted and the dividend and bonus recommended declared.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.

The forty-first ordinary meeting of this Company was held on Wednesday, Sir John Pender presiding.

The **Chairman**, in moving the adoption of the report, said the receipts of the half-year amounted to £96,261, as against £106,860 in the previous half-year, showing a decrease of £10,598, and as compared with the income of the corresponding half-year of 1892, when it was £115,893, the decrease was £17,750. They had placed £20,000 to the reserve fund, which now stood at a very large figure; but he thought they were only right in carrying forward such a large amount, as they had never been able to find out the age of a cable, although they were keeping them in the same satisfactory condition. Continuing, he said their concession expired with the Brazilian Government; but they had sent out an agent to renew, if possible, the agreement for the next 20 years. The Government was undergoing a change, and they hoped that when the civil war was over a Government would be established, and with that prosperity would come. They had, moreover, obtained the power to lay a cable between Brazil and the Argentine, by which they would be able to compete with the American company. In conclusion, he thought the coming half-year would be one of some considerable interest.

The **Hon. W. St. John Brodrick**, **M.P.**, seconded the motion, which was adopted.

BUSINESS NOTES.

Foreign Office.—The Foreign Office is to be lighted by electricity.

Newark.—The Corporation is to be asked to establish a supply of electricity.

Ormskirk.—An electric organ has been dedicated in Ormskirk Church by Archdeacon Clarke.

Western and Brazilian Telegraph Company.—The receipts for the week ended April 27 were £2,825.

Prices of Dynamos.—The Governors of the University College at Bristol ask for prices of dynamos and motors.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 29th ult. amounted to £667.

Islington.—The seal of the Vestry has been attached to the conveyance of the site for the electric lighting station at Holloway.

York.—It is intended to adopt the high-tension system, and the surveyor to the Town Council is to report on the tenders of four firms.

Personal.—Mr. T. H. Parker, the son of Mr. T. Parker, has commenced business at Stourbridge as a consulting electrical engineer.

Cuba Submarine Telegraph Company.—For the month of April the receipts were £46 less than for the corresponding period of 1893.

Eastern Telegraph Company.—The receipts for the month of April were £56,751, as against £56,469 for the corresponding period of 1893.

Southampton.—A committee of the Town Council is considering the question of acquiring the undertaking of the local electric light company.

Kensington.—The Vestry have authorised the Notting Hill Electric Lighting Company to proceed with the extension of mains in Holland-park.

Dublin.—The Town Council have accepted, at £8,050, the tender of Messrs. J. Fowler and Co., Limited, of Leeds, for extensions of the electric lighting plant.

Digitized by Google

Kingston.—Extensions in the plant are to be made, and for this purpose it is proposed to borrow £6,000.

Folkestone.—Another meeting has been held at the Town Hall to protest against the introduction of the electric light. The proceedings were very noisy.

Eastern Extension Telegraph Company.—For the month of April the receipts show a decrease of £2,911 as compared with the corresponding period of 1893.

Basingstoke.—The Town Council are about to employ an electrical engineer, at a fee not exceeding 20 guineas, to report on the cost of public lighting by electricity.

Baslow.—It is probable that the buildings of the Baslow Hydropathic Company, Limited, will be lighted by electricity. The directors are considering the matter.

Appointment Open.—As mentioned in our last issue, the Corporation of Sunderland invite applications by the 12th inst. for the position of municipal electrical engineer.

Sunderland.—It is expected that public electric lighting will be commenced at the end of the year. Prof. Kennedy is to prepare a report on the number of lamps to be erected.

Consolidated Telephone Construction and Maintenance Company.—The directors recommend a dividend at the rate of £2 per cent. per annum, less tax, for the year ending March 31.

Stock Exchange Quotation.—An application has been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation to, the shares of the Waterloo and City Railway Company.

Lighting of Ironworks.—The Lillieshall Company, Limited, are about to instal the electric light at one of their extensive works—namely, at the Snedshill Ironworks and Rolling Mills near Oakengates, Shropshire.

Burton-on-Trent.—Dr. Mason has decided to adopt the electric light for his new house and museum. The contract for the installation has been placed in the hands of Messrs. W. J. Furse and Co., electrical engineers, of Nottingham.

New Works.—The Hayesmoore Company inform us that they have opened works for the manufacture of electrical specialities at 10, Union-mews, Union-street, W. The head office of the company remains at 53, Crewsdon-road, Clapham-road, S.W.

Sale by Auction.—On Wednesday next, Mr. J. C. Stevens will sell by auction at 38, King-street, Covent Garden, a large quantity of apparatus removed from the School of Electrical Engineering. Further particulars are given in our advertisement columns.

Gravesend.—The first house in this town to be lighted electrically is Canterbury House, the residence of Mr. Hubert Edmonds. He has carried out the installation himself. The dynamo, of his own make, is driven by an engine constructed by Messrs. Drysdale and Co., West-street, Gravesend.

City and South London Railway.—The receipts of the Company for the week ended April 29 were £901, against £792 for the same period last year, or an increase of £109. The total receipts for the first half-year of 1894 show an increase of £153 compared with those for the corresponding period of 1893.

West India and Panama Telegraph Company.—The report for the six months ended December 31 states that the revenue amounted to £34,265, against £38,358 for the corresponding half of 1892. The expenses were £22,602, against £25 155 A dividend of 9d. on the ordinary shares, absorbing £3,312, is recommended.

Mill-Lighting.—Messrs. Bennett and Druce, of Preston, have received instructions from Messrs. Tootal, Broadhurst, Lee, and Co., Limited, Bolton, to entirely reorganise the electric light installation at present erected in their extensive mills. The installation will have to be practically refitted throughout, and will be considerably extended.

Country Mansion Lighting.—Messrs. Drake and Gorham have been entrusted with the erection of an installation at Greenway House, the country residence of Mr. T. B Bolitho, M.P., with about 120 lights. In this case it has been considered necessary to arrange for a petroleum-engine to drive an E.C.C. shunt-wound dynamo to charge 53 D.P. accumulators.

Coventry.—At a meeting of the Town Council last week, Mr. James asked whether the Council contemplated taking any action against Mr. Graff Baker in respect to the repairs of the roads on the tramway lines. The Mayor said that the matter had been before the General Works Committee and adjourned for a month. The month had almost expired, and they would be obliged to take action.

Lancashire Rubber Company, Limited.—This Company has been registered with a capital of £70,000 in £5 shares. The object is to acquire the business of a rubber manufacturer now carried on by A. McDougal at Holland-street, Pendleton, Salford, under the style of the Lancashire Rubber Company, and to acquire certain letters patent relating to an improved process of waterproofing.

Sale of Materials.—As stated in our advertisement columns, Messrs. Welsby and Bousfield have received instructions from the Executive Committee of the late Industrial and Fine Arts Exhibition, St. Augustine's Bridge, Bristol, to sell by auction, on the site, on Thursday, the 10th inst, the materials of the industrial section of the exhibition buildings, together with the whole of the electrical fittings.

Edinburgh.—At a meeting of the Electric Lighting Committee of the Edinburgh Town Council, a remit has been made to the consulting and resident engineers to prepare and submit a report as to the capital and annual cost of, and the number of lamps necessary for, the electric lighting of George-street, St. Andrew-square, Charlotte-square, and streets leading into these thoroughfares from Princes-street.

Worcester.—At the meeting of the Watch Committee last week, the Mayor stated that Mr. Hadley had arranged to give them a piece of land which was needed for the turbines at the electric lighting works, on condition that the Council made up the bank and planted it with chestnut or mountain ash trees. It was stated that the committee hoped to be ready to supply the electric light by October.

Submarine Cables Trust.—The trustees of the Submarine Cables Trust report that the revenue for the year to April 15, including the balance of £80 brought from the previous accounts, amounted to £22,673. The expenses amounted to £1,301, and the payments on account of the coupons to £21,131, together £22,432, leaving £240 to be carried forward. There is no change in the investments of the Trust.

Electric Lighting in Leather Works.—The electric light has been adopted in the leather-dressing works of Messrs. E. Turney and Co., and Messrs. Bayley and Co., Nottingham, and in both cases the contracts for the installations have been placed in the hands of Messrs. W. J. Furse and Co., of that town, who have adopted the E.C.C. dynamo, the power being derived from a Tangyes horizontal steam-engine.

Church-Lighting.—Considerable alterations have been made in the electric lighting of St. Paul's Church, Knightsbridge. All the handsome pendants for lighting the nave are now fitted with 32-c.p. lamps, enclosed in ground-glass shades, and the large crucifix over the choir screen is illuminated by reflected light with good effect. This work has been carried out by Messrs. Allpress and Co., of 55, Victoria-street, Westminster.

Branding Bacon by Electricity.—Some time ago, Messrs. Allpress and Co., of 55, Victoria-street, S.W., suggested to the Wiltshire Bacon Curing Company that they should utilise the electric current during the daytime for heating electric branding-irons, which should be used in place of the old-fashioned brands. This suggestion was adopted, and the company are now branding their bacon by this new method, which has given general satisfaction.

Newcastle.—At a meeting of the Newcastle City Lighting Committee an application was considered from the gas company requesting payment of upwards of £200 for the half-year for lamps which have been discontinued in various parts of the city in consequence of the erection of electric lamps. The town clerk was instructed to write to the company intimating that the committee could not see their way to recommend the Council to pay the sum named.

Toxteth.—At a meeting last week of the Toxteth Board of Guardians, Mr. Jones moved the appointment of a committee to make preliminary enquiries into the advisability of adopting the electric light in the workhouse. Mr. Johnston remarked that their gas was now costing them £500 a year. They had a 12-h.p. steam-engine which did their laundry and other work during the day, and this engine might afterwards be used to work a dynamo. He supposed that unless there would be an actual saving the Board would not go in for electric lighting. The motion was carried.

City.—At the last sitting of the Commission of Sewers, Mr. Ross, reporting on the number and cost of the gas lamps displaced by the arc lamps in the main thoroughfares, said the electric lights, numbering 479 arc lamps, cost £12,454 per annum, whereas the 1,315 gas lamps cost for lighting and maintenance £4,631 per annum. Mr. McCarthy, commenting upon the enormous increase, asked whether the Commission intended lighting the side streets by electricity, which would cost another £10,000 a year. Mr. Burmester said the Streets Committee was considering that point. The subject then dropped.

Belfast.—The Gas Committee of the Town Council have transferred £10,000 from the gas fund to the electric light fund to put the Electric Committee in a position to pay their present outlay. The Electric Committee report that Messrs. Scott and Sillars, contractors for the road work, have made considerable progress with the opening up of the streets and formation of the culverts. The laying of the mains in the compulsory area by the Corporation workmen is also being proceeded with. Mr. M'Cowen entered upon his duties as resident electrical engineer on the 26th ult., and is superintending the execution of the works under the direction of Prof. Kennedy.

Derby.—The Local Government Board have sanctioned the borrowing of £5,000 for the extensions of the electric lighting of Derby, repayable in 20 years. Between October 10 and March 31 the amount due from customers for electrical energy was £474. 7s. 10d., and the estimated amount due for street-lighting was £505. 15s. It is intended to supply the electric light to the two police stations and the market hall. The Art Gallery Committee of the Town Council have requested the Council to grant a further sum of £29. 3s. 1d. for wiring and fittings for the electric light, being the amount certified by the engineers (Messrs. Bramwell and Harris) to be due to Messrs. Paterson and Cooper for extras. The Council granted £109. 6s 4d. on September 6. The report has been accepted.

Buckingham.—The Lighting Committee of the Town Council have considered the letters sent in by the gas company and the electric light company. The former still adhered to their price of 4s. 6d. per 1,000ft., which could in no way be entertained, seeing that the agreement with the electric light company had been made—and the lamps, which are situate in and adjacent to the Market-square, have been fitted and lighted with

Digitized by Google

the new illuminant. The electric light company in their letter referred to the shortness of time they were allowed in which to send in a tender for the lighting of the remaining lamps, numbering about 80, and scattered as they are all over the town. The committee recommended that further time should be given to the proprietors, Messrs. Parr and Gillies, and this was adopted without the slightest dissent by the Council.

Guildford.—At a meeting of the Urban Sanitary Authority the Town Clerk stated that he had received a letter from the Board of Trade saying that Sir Thomas Blomfield would be glad if the town clerk would call on him at his office at an early date with reference to the question of the electric lighting. It was decided that he should do so. The members of the Authority acting on the Fire Brigade Committee reported that they had given consideration to the proposal made to establish a system of call bells connected with the firemen's residences at an estimated charge of £22 per annum, and they had also received a proposal for connecting the police station and Mr. Heard's stables by a private wire at an estimated cost of £3 per annum, but the committee did not at the present time recommend the Authority to take any action with regard to either proposal. The report was adopted.

South Staffordshire Tramways.—In the Chancery Division on Wednesday the petition of Mr. Alfrew Dawson and other shareholders for the winding up of the South Staffordshire Tramways Company, Limited, came on for hearing. Mr. Herbert Reed, Q.C., in support of the petition, said the company had paid no dividends since 1887, and in April, 1893, a debenture-holders' action was commenced, under which receivers and managers were appointed, consisting of Mr. Sully and the chairman of the company, Mr. Wain. The petitioners attributed the condition of the company to a contract entered into by the directors with the Electric Construction Company. Mr. Buckley, Q.C., for the company, contended that this contract was very favourable to the tramway company, and, the charges made against the directors having failed, the petition ought to be dismissed. The hearing of case was adjourned.

Bradford.—The Gas and Electricity Supply Committee of the Bradford Corporation have decided that the scheme for supplying the electric light to the out-townships, Frizinghall, Allerton, and Heaton, should be pushed on without delay. A deputation has been appointed to visit the Halifax electricity works to inspect the process in use there for generating electricity in connection with the defæcation apparatus, the idea being that the power necessary for the sewage defæcation works at Frizinghall should be similarly utilised. A suggestion was made that circulars should be issued to ascertain how many of the residents in the townships named would be disposed to avail themselves of the supply, but many members thought it best to leave the matter alone for the present. It was also suggested that applications for the supply of electric light from the present works in Canal-road should be invited from residents and business people in Barkerend-road and Great Horton-road, but no action was taken. Plans are being prepared for the Frizinghall station.

Fareham.—A public meeting of the ratepayers has been held to consider the question of entertaining an offer of the Fareham Electric Lighting Company to sell the business and undertaking of the company to the Local Board. The Rev. T. G. Browne, who occupied the chair, read the letter sent by the company, offering to sell their works to the Local Board. Captain Ramsay proposed that the offer of the electric light company to sell their works by valuation be accepted, this being seconded by Mr. H. Plummer. Mr. Porter moved an amendment to the effect that the Local Board abandon their offer to purchase the electric light plant. He criticised very severely the several balance-sheets issued by the company, and described the whole concern as being valueless. He stated that out of £4,155 of subscribed share capital, £1,785 in shares, or three-sevenths of the whole, were held by Mr. Blake's family. Mr. Abraham seconded. The Chairman then put the amendment, in favour of which there were about 80 hands raised, and about 15 against. He therefore declared the amendment carried. Mr. Blake then said that, as he noticed a number of juveniles had voted, he demanded a poll.

Lighting of Ipswich.—A resolution was moved by Mr. J. Pratt at a meeting of the Town Council last week that the Urban Sanitary Authority should apply for a provisional order. The plant to light the district suggested (2⅔ miles) would require approximately an expenditure of £9,036, exclusive of private fittings to houses. The estimated cost of maintenance was £1,842, and this, with £274 interest and repayment on a 25 years' loan, would make £2,116 total annual expenditure. The charge of 6d. per Board of Trade unit is equivalent to gas at 3s. per 1,000. If at this rate they obtained 80 consumers using 15 lamps each (say, 10 for shop and five for private house), the revenue would be £1,600. In street-lighting the cost of 50 arc lamps at £15 each would be about £750 per year. The total revenue would therefore be £2,350, or £234 more than the expenditure. He therefore hoped that the scheme would be free of cost to the ratepayers. Messrs. F. Suter and Co., electrical engineers, London, reporting on the estimate, congratulated Mr. Pratt upon the reliability of his estimate, adding that his plan would easily supply 2,000 lamps 16 c.p., or 4,000 of 8 c.p., which would leave a margin for any number of lights that might be required in the district for some years to come. They felt confident that the plant could be obtained for less than £9,000. Mr. Pratt supplemented the above statement with some further observations. Mr. W. A. Churchman seconded the motion. After some discussion, the resolution was agreed to. The following committee was appointed: the Mayor, the Deputy-Mayor, Alderman A. Wrinch, and Messrs. W. A. Churchman, H. W. Raffe, E Catchpole, and J. Pratt, with the same powers as other committees of the Corporation in regard to the expenditure of money up to £100.

African Transcontinental Telegraph Company.—The report from December 27, 1892, when the Company was incorporated, to March 31 last, reminds the shareholders that in anticipation of formation a confidential prospectus was issued December 7, 1892, inviting subscriptions for shares. It was then proposed to raise a capital of £400,000. but ultimately the Company was registered with a capital of £140,000 only, being the estimated cost of constructing the line of telegraph from Salisbury, in Mashonaland, *viâ* Lake Nyassa and Lake Tanganyika to Uganda. Subscriptions for a substantial sum were received, but before determining to proceed to allotment the directors obtained from Mr. Cecil Rhodes an agreement to subscribe for the balance of the share capital at par, as explained in the circular sent out on March 16, 1893. In pursuance of this agreement, as and when moneys have been required, shares have been applied for by, and allotted to, Mr. Rhodes. The directors decided to first construct the 400 miles of the line between Salisbury and Zomba, the seat of administration of the Nyassaland Protectorate, and work was commenced simultaneously from each of these places with a view to meeting at a point near Tete on the Zambesi River. In furtherance of this project, 200 miles of material were shipped to Beira for transmission to Salisbury. the remaining 200 miles of material being shipped to Chinde for transport to Chikwawa on the Shiré River, about 60 miles south-west of Zomba. The outbreak of the Matabele war prevented operations during the dry season in respect of the construction of the southern or Salisbury-Tete section, and by advices dated the end of February, the directors regret to learn that since the war little or nothing had been accomplished, the rivers having been in flood, and transport impracticable. In the northern section between Chikwawa and Tete, good progress has been made.

Bristol.—At a meeting of the Electrical Committee of the Town Council it was resolved, on the motion of Mr. Tryon, that the resident engineer be instructed to report on the cost of extending the mains for private supply to Clifton and Tyndall's Park. On the motion of Mr. Bastow, North-street and Stokes-croft were added to the list, and, on the motion of Mr. Lloyd, Bedminster was also included. The report will not be ready for a month. The committee were informed that the new clocks and apparatus for ascertaining the current consumed in the daytime will be shortly put in hand, and that the patentee (Mr. Gisbert Kapp) had arranged with Messrs. Kemp Bros., of Union-street, Bristol, for the manufacture of the clock and apparatus on his behalf. The committee determined (subject to the application for the £24,000 loan being sanctioned) to extend their mains to Redcliff-hill at a cost of £855. Distributing mains will shortly be laid between Phippen-street and Bedminster Bridge, a number of applications for the light having already been received, including one for Redcliff Church, which it is intended to light throughout with electricity. A Local Government Board enquiry has been held to consider an application by the Town Council to borrow £42,000, of which £24,000 is required for electric lighting. In connection with the latter, Mr. Preece gave details of the expenditure already made and the projected expenditure on the new works. He mentioned that the excess of expenditure was not due to any error in the original estimate, but to extraordinary difficulties that arose in erecting the building. In preparing for the foundations of the structure they came across ground that had been made, and could not be utilised without being piled. Piling and constructing a retaining wall cost nearly £10,000. The original estimate for the building was £5,000; but subsequently applications for installations more than were anticipated came in, which led the committee to have a larger building erected and more plant placed therein, which brought up the cost to £13,000. The result was that Bristol had the best central electric lighting station in the kingdom so far as the structure was concerned. It was intended to expend about £15,000 more capital on new works to meet increasing wants. One extension had already been sanctioned, and another extension was under consideration.

Lighting at Chelmsford.—The Town Council last week received a letter from Messrs. Crompton and Co., calling attention to the manner in which the Council had treated their repeated requests for a better water supply. The matter was referred to the Sanitary Committee. The Town Clerk reported at the same meeting that he had received from the Board of Trade the draft provisional order for electric lighting in the form in which they proposed to issue it. It was proposed by the Council to insert that the purchase be limited to all such parts of Messrs. Crompton's undertaking as were used solely for the public and private lighting of the borough. The order, as settled by the Board of Trade, however, simply provided that Messrs. Crompton and Co. should sell to the local authority the undertaking authorised by the order, with all lands, buildings, materials, and plant used in connection therewith. He (the town clerk) had since, in a correspondence with the Board of Trade, pointed out the reason of the Council in wishing to have the undertaking defined more specifically, and he had also had a long interview with Sir Thomas Blomfield at the office of the Board of Trade on the matter. Sir Thomas Blomfield said they could not put in the words suggested, because it would be limiting the purchase to the public and private lighting of the town, and that if the Council purchased the undertaking they must purchase all such parts of the plant and material and so on as should be necessary for supplying energy within the whole of the borough, whether used for the public or private lighting of the town or for other purposes. He further said that the word "undertaking" did not comprise, and could not be held to comprise, any portion of

Digitized by Google

Messrs. Crompton's business except such portions as should be necessary for the supply of energy within the borough. The same difficulty had arisen at Liverpool and Reading, and had been settled by the insertion of words which it was now proposed to insert in the Chelmsford order. Alderman Chancellor said the alteration meant that they would have to pay compensation to Messrs. Crompton and Co. for withdrawing their private business from these premises if ever they wished to purchase the undertaking. The purchase clause would be absolutely prohibitive. Alderman Brown thought, on the other hand, that the Board of Trade had protected the interests of the Council further than they had protected themselves. He thought Mr. Chancellor was decidedly wrong in his interpretation of the matter. Mr. Britton, chairman of the Lighting Committee, was of the same opinion as Alderman Brown. Mr. Whitmore said he could not see any great difference between the two clauses, excepting that the clause suggested by the Board of Trade gave the Council an advantage. They only asked for power to purchase the business as far as the public and private lighting was concerned, but by the alteration they would have power to purchase the whole of the energy, whether it was for cooking, or for warming, or for driving a tramway through the town. Therefore, he thought they were placed in a better position by it. After further discussion, it was agreed to leave the final settlement of the form of the order in the hands of the Board of Trade.

PROVISIONAL PATENTS, 1894.

APRIL 23.

7994. **An improved electrolytic trough or cell.** Ernest de Pass, 78, Fleet-street, London. (Hermann Thofehrn, France.)

7995. **Improvements in fittings for electric lamps.** Hugo Hirst, 73, St. Stephen's-road, Upton Park, London.

8007. **An automatic switch for telephones and other electrical apparatus.** George Lee Anders and Walther Kottgen, 31, Queen Victoria-street, London.

8011. **Improvements in appliances for increasing the duration of the top carbon of electric arc lamps.** Francis Jehl and Fritz von Hardtmuth, 28, Southampton-buildings, Chancery-lane, London.

APRIL 24.

8043. **An improved insulating cleat for supporting conducting wires for electrical circuits.** Horace Bartlett Wyman and Albert Clark Goodwin, 52, Chancery-lane, London. (Complete specification.)

8045. **Electric bell for application to bicycles, tricycles, and other cycles.** Woolf Goldberg Woolf, 160, Cassland-road, South Hackney, London.

8061. **Improved apparatus and process for electro-chemical decomposition.** Henry Carmichael, 55, Chancery-lane, London. (Complete specification.)

8115. **Improvements in apparatus for the manufacture, electrolytically, of tubes and other articles of circular section.** Francis Edward Elmore, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

8125. **Improvements in dynamo-electric machines and electric motors.** Herbert Napier Prentice, 47, Lincoln's-inn-fields, London.

8149. **Improvements in electrical measuring instruments.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (John van Vleck and Edward Weston, United States.) (Complete specification.)

APRIL 25.

8215. **Automatic current distributor for multiple telegraphic transmission.** Ignace Bielski, 4, South-street, Finsbury, London.

8218. **Improvements in or connected with electric signalling or communicating apparatus.** Charles Stuart Jones and Henry Charles Collier, 4, South-street, Finsbury, London.

8224. **Improvements in electric lighting.** James George Willcox Aldridge, 40, Chancery-lane, London.

APRIL 26.

8238. **Improvements in electro-medical apparatus.** Augustus Basil Holt Clerke, 75, Church-road, Horfield, Bristol.

8240. **An improved ceiling rose for suspending electric pendant lamps.** Francis William Ball and John Hugh Winter, Bristol Bank-buildings, Bristol.

8273. **An improved form of shade tilt for electric light flexible-wire pendants or other similar fittings.** Ernest Alexander Claremont, Cooke-street, Hulme, Manchester. (Complete specification.)

8292. **Improvements in or relating to the charging of electrical accumulators or secondary batteries automatically.** John Evelyn Liardet, 9, Warwick-court, Gray's Inn, London.

8307. **Improvements in and connected with arc lamps and the regulation of the feeding of their carbons.** James Jamieson Fyfe, 41, Hillside.road, Stamford Hill, London.

8315. **Electrically-propelled tramway vehicles.** Walter Charles Bersey, 53, Chancery-lane, London.

8317. **Improvements in switches for use at central stations of telephone systems.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (The Antwerp Telephone and Electrical Works (Société Anonyme), Belgium.)

8328. **Improvements in electric condensers.** George Threlfall, 46, Lincoln's-inn-fields, London. (Richard Threlfall, Australia.)

APRIL 27.

8343. **An improved globe or shade holder for electric, gas, or other lamps.** George Frederick Sanders, 36, Temple-street, Birmingham.

8350. **Improvements in electric batteries.** Henry Harington Leigh, 22, Southampton-buildings, Chancery-lane, London. (Vohwinkel, Austria.)

8376. **Water-gauge with electric alarm for steam-boilers, water-towers, and reservoirs.** Heinrich Tommes and August Wellner, 5, Metzerstrasse, Cologne. (Complete specification.)

8412. **Improved method of and means for controlling electric currents.** Anthony Frazer, 1, Furnival-street, Holborn, London.

APRIL 28.

8443. **An improved arrangement of electrical contact surfaces for producing electrical effects in theatres, etc.** Alexander Fairley, 4, Boothroydon, Warley-road, Blackpool.

8478. **Improvements in electrically-propelled vehicles.** Ernest John Clubbe and Alfred William Southey, 53, Chancery-lane, London.

8480. **Improvements in and relating to galvanic batteries.** Thomas Henry Rushton, 115, Cannon-street, London.

SPECIFICATIONS PUBLISHED.

1893.

6751. **Extracting chromium by electrolysis.** Placet and Bonnet.

11176. **Electric bell, etc., indicators.** Gent and others.

12458. **Dynamo-electric machines.** Hutin and Leblanc.

1894.

3729. **Dynamo-electric machines.** Claremont.

4083. **Electric arc lamps.** Schleyder.

4144. **Electrodes for arc lamps.** Clark.

4539. **Joint for wires for electrical conductors.** Dieselhorst and others.

NOTES.

"**Micamen**" should read note on "Continental Trades' Directory."

Calcutta.—The subject of introducing a public supply of electricity is in abeyance.

Biella.—The depôt of the local tramway company has now been electrically lighted.

The Latest.—A penny-in-the-slot electric boot-cleaning machine. We should like to see it.

Madras.—The laying down of the permanent way of the electric tramway is progressing.

Novara.—The central station for the supply of electric light has just been set in operation.

Rating of Machinery.—The Rating of Machinery Bill passed the second reading on Wednesday.

Dr. Herz.—The proceedings against Dr. Herz have been abandoned. He will now possess a happy *herz.*

Telephony in India.—Telephonic communication between different offices at railway stations is being established.

Dresden.—Arrangements have been made to construct a central electric light station on the site of the gasworks in the Stiftstrasse.

Train-Lighting.—The North-Western Railway Company of India are considering the question of lighting their trains by electricity.

Society of Chemical Industry.—A paper on "The Commercial Electrolysis of Fused Salts," by Mr. Claude Vautin, was read on Monday before this society.

Personal.—Mr. C. Ashmore Baker, A.I.E.E., has established himself at 28, John-street, Bedford-row, W.C. where he will carry on his business of consulting electrical engineer.

Cable Extension.—The laying of the second section of the alternative Singapore-Hong-Kong cable—namely, that between Labuan and Hong-Kong—has now been completed, and the line opened for traffic.

The Industrial Exhibition.—Among the exhibitors at the Industrial Exhibition now open at Earl's Court is the Brush Electrical Engineering Company. It is proposed to establish electric fountains in the grounds.

Klausenburg.—The local authorities of this Transylvanian town have decided to introduce the electric light. The concession has been given to Herr Josef Körner, a local merchant. Work has been commenced.

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will take place on Friday next, the 18th inst., at 28, Victoria-street. A paper by Mr. P. W. Paget, entitled "Notes on Gas-engines," will be read.

Time Indicator for Railways.—Mr. Ludwig Kohlfürst describes in the *Elektrotechnische Zeitschrift* of May 3 a system of electrically transmitting time to railway station clocks. The system is in use on the lines of the Imperial Railway Administration in Berlin.

Dynamos and Transformer Construction.—Mr. James Swinburne, M.I.E.E., will commence, on the 29th inst., a course of lectures on this subject to the students of the Electrical Standardising, Testing, and Training Institution, Faraday House, Charing Cross-road.

Cheap Telephony.—Mr. Henniker Heaton, it is said, looks forward to the time when every private house in England will be supplied with a telephone service for £3 a year, and when it will be possible to speak with America and Australia. Mr. Heaton is certainly very sanguine.

Saint-Quentin.—The gasworks have had to commence operations for the supply of electricity according to their contract. Gas motors of 70 h.p. will be employed driving continuous-current dynamos. The three-wire system is to be adopted. The tariff price is 16 centimes per hectowatt-hour.

Bournemouth.—We understand that on Monday evening the engines at the electric light works had to be stopped, and that there was a cessation in the supply of light. There was, it appears, a great noise set up in the telephone wires. On Tuesday the supply was resumed to some of the consumers.

Utilisation of Atmospheric Electricity. — A scheme has been presented in all seriousness to the French Academy of Sciences for the revolution of industry! It is nothing more or less than the old-fangled notion of extracting electricity from the atmosphere and using it for lighting and other purposes.

Telephony in Italy. — The Italian Telephone Administration some time ago granted a number of concessions for working telephone exchanges. Our contemporary *L'Elettricità*, in its issue of May 6, gives a table of the towns having telephonic facilities, the number of subscribers, annual rentals, etc.

Exhibition at Bucharest.—The co-operators of Roumania propose to hold their fourth exhibition at Bucharest this year, to commence on August 26 and to close on November 12. In order to encourage foreign manufacturers to take part in the exhibition, space is to be set apart for an international section.

Temesvar.—The municipal electric lighting station, which is the only municipal electric plant in Hungary, made a profit of 22,000 florins on its last year's working. In consequence thereof, the price for current has been lowered to 1·8 kreuzers per lamp-hour, and large consumers will be given a rebate up to 15 per cent.

Tramway Traction in France.—The Compagnie Générale Francaise de Tramways, whose annual meeting takes place on the 21st inst. at 60, Rue de la Chaussée d'Antin, Paris, states that they have been compelled to substitute mechanical (electrical) traction for horse haulage at Havre, Marseilles, Nancy, and Genoa.

Legislation in Italy.—The development of electrical engineering in Italy has induced Mr. Boselli, the Minister of Commerce, to introduce a Bill for regulating the long-distance transmission of energy and its distribution for industrial purposes. The details of the proposed legislation are set forth by Mr. A. Banti in *L'Elettricità* of April 22.

Dublin.—Mr. M. Ruddle, the electrical superintendent of the Dublin central station, has written a letter to the *Freeman's Journal* to correct certain statements made by the latter in regard to danger and inconvenience alleged to have been caused on the occasion of a fire in Henry-street, when a circuit was broken through the fall of a wall on to a street arc lamp.

Cork Telephones.—Under a new regulation of the National Telephone Company, subscribers availing of the "unlimit" (£10 and over) system can communicate with Queenstown and Midleton without extra charge; £5 subscribers are asked to pay 3d. for three minutes or any fraction thereof. Hitherto there was a general charge of 6d. for five minutes' communication with Midleton and Queenstown.

Digitized by Google

Lithanode Cells.—Recent improvements introduced in the manufacture of lithanode have tended to reduce the cost, and the Lithanode and General Electric Company, Limited, have therefore decided to considerably reduce the price of their electric lighting and other lithanode cells. The company's reduced price list shows that their prices compare favourably with those of any other makers of secondary batteries in this country.

A Question of Failures.—It is rather a one-sided affair for the Bath Electric Lighting Company, or, for that matter, any other company supplying the electric light, to be mulcted in fines for failures when the local gas company is allowed to be free from such onus. At all events, the Bath Electric Light Company have the satisfaction of knowing that all their dirt is washed entirely away, even if the gas company does not get a clean bath.

A Goak.—A correspondent sends us the following clipping from *Pearson's Weekly* of May 12, 1894: "Mica is chiefly made use of for dynamos, electric alternators, and transformers, and also for placing at the ends of cables for the purpose of absorbing the electricity which lingers in the wire after a message has been sent, the presence of which would affect subsequent messages." Surely a little knowledge is a dangerous thing if this information is seriously given.

Might Very Well Be.—Ordinary young man, to learned professor: "What you say, then, is that the brilliant aurora borealis and other such fireworks of Nature are all brought about by electricity?" Professor: "Yes; these phenomena are undoubtedly electrical." Young man: "Well, now, I wonder if they are a sort of reservoir for all the bad language used through the telephone?" Perhaps Mr. Preece may have a desire to be heard upon the subject.

A Long Electric Railway.—The construction has been commenced of the Chicago and St. Louis Electric Railway. Dr. Wellington Adams, the promoter of the line, has been perfecting his plans and arranging to raise money. It is now said there is no longer any doubt about the line being pushed through to completion. It is said the General Electric Company has no hesitation in guaranteeing that it can build high-speed motors capable of travelling 100 miles an hour with perfect safety.

Bozen.—Herr Oscar von Miller has explained to the Municipal Lighting Committee of Bozen the project for the electric lighting and power transmission installation for Bozen and Meran. He recommends that a generating station should be established on the Töll above Meran. Current would be taken to Bozen by means of overhead conductors. The estimated cost for a joint scheme for the two towns is £71,600 for 2,000 h.p., £88,400 for 3,000 h.p., and £114,800 for 6,000 h.p.

Coventry.—Mr. F. H. Tulloch, Local Government Board inspector, held an enquiry on Wednesday into the proposal of the City Council to borrow £20,000 for the purposes of electric lighting. The Town Clerk stated that powers were given to the Corporation to light the city with electricity in 1891, and they were required to light certain streets within a certain time, and it was proposed to do that at once out of the loan now asked for. The charge was to be 8d. per Board of Trade unit.

Royal Meteorological Society.—An ordinary meeting of this society will be held at 25, Great George-street, Westminster, on Wednesday next, at 8 p.m. Papers on the following will be read: "The Relative Frequency of Different Velocities of Wind," by Mr. William Ellis, F.R.S.; "Audibility of 'Big Ben' at West Norwood Under Certain Meteorological Conditions," by Mr. William Marriott, F.R.Met.Soc.; and on "Earth Temperatures at Cronkbourne, Isle of Man, 1880-1889," by Mr. A. W. Moore, M.A.

Charing Cross-Hampstead Railway.—The London County Council on Tuesday approved of the withdrawal of the petition of the Council against the Bill promoted for the construction of this railway. The Unopposed Bill Committee of the House of Commons on Tuesday passed the Bill promoted by the Charing Cross, Euston, and Hampstead Railway Company. The object of the measure is to acquire additional lands for stations, etc., in the parishes of St. Martin's-in-the-Fields, St. Anne's, Soho, St. Giles-in-the-Fields, and St. Pancras.

The Heilmann Locomotive.—This locomotive, to which we have referred on previous occasions, was tested on Wednesday on the Western of France Railway. The locomotive drew a special train from the St. Lazare Terminus in Paris to the Seine et Oise Station, a distance of 33 miles, performing the journey in 55 minutes. The train was composed of five coaches and a dynamometric brake van, and at certain portions of the line a speed of 65 miles an hour was attained. The locomotive subsequently took the ordinary train, No. 54, back to Paris.

The "Medical Battery" Company.—An application has been made to Mr. Justice Williams to allow the debenture-holders' receiver for the "Medical Battery" Company, Limited, to continue to sell the Harness "electric" belt. His Lordship said he was loth to allow an officer of the court to continue to sell these goods by such methods as had previously been resorted to. Counsel for the receiver assured his Lordship that the sale was being carried on without any false representation or guarantee being given as to efficacy. The carrying on of the business for a further two months has been granted to realise the assets.

Buxton and Chesterfield.—The Electric Lighting Provisional Orders Bill (No. 1) has been before Mr. Thomas, the examiner of the House of Commons, for proof of compliance with Standing Orders. The object of the Bill is to confirm certain provisional orders made by the Board of Trade to enable, among other local authorities, the Buxton Local Board and the Corporation of Chesterfield to use electricity under the Electric Lighting Acts of 1882 and 1888. Formal proof having been given, the examiner decided that the Standing Orders had been complied with, and the Bill will in due course be reported for second reading.

Laying of New Mains.—The Kensington and Knightsbridge Electric Lighting Company intend to lay additional mains in Brompton-road, and to lay mains on both sides of Beauchamp-place. Messrs. Siemens Bros. and Co., on behalf of the Hampstead Vestry, are about to lay underground cables and to construct underground transformer-chambers in Finchley-road; and the St. James and Pall Mall Electric Light Company intend to lay new feeder and distributing mains in New and Old Burlington streets, Burlington-gardens, Regent-street, Cork-street, Vigo-street, Glasshouse-street, Brewer-street, Air-street, Piccadilly, Great Windmill-street, and Wardour-street.

Telegraphists of the Late Submarine Cable Company.—Mr. A. Morley, in answer to a question in the House of Commons on Monday, said the last memorial from the officers who were in the employ of the late Submarine Telegraph Company, asking that their period of service with the company should be recognised towards their pension was dated October 23 last, and it was answered on the 10th of the following month. The subject had, on more than one occasion, been considered by the

Digitized by Google

Treasury, and the officers in question were aware not only of the steps which had been taken to deal with their representatives, but also with the result.

Continental Trades' Directory.—Some correspondents ask us to give the name of the publication which takes on the Continent the position occupied by "Berly's Electrical Trades Directory" in England. For their benefit, and that of other firms, we have investigated the matter, and believe that the following directory will meet every requirement: the "Adressbuch der Elektricitäts-branche und der damit verwandten Geschaftszweige." It is published in two parts. The first refers to Germany alone, and the second to the whole of Europe. Either part may be obtained separately. The publishers are Messrs. Eisenschmidt and Schultze, of Leipsig.

Dr. K. E. Zetzsche.—The death is announced of Dr. K. E. Zetzsche, the electrician. He was born at Altenburg in 1830, and studied at the Dresden and Vienna Polytechnics. In 1856 he entered the Austrian telegraph service, and worked in Vienna, Padua, and Trieste. In 1858 he taught mechanics and mathematics at a technical college in Chemnitz, and in 1876 became professor of telegraphy at the Dresden Polytechnic. He was one of the chief contributors to the "Handbook of Electrical Telegraphy," published in Germany, and wrote various other books, besides being a contributor to a number of technical papers. He was likewise the inventor of some electrical apparatus.

The Hermite System.—An analysis of the reports on the Hermite system by Dr. Kelly and Dr. Piton, and to which we referred in previous issues, was given in the *Standard* of Monday's date. That paper concludes with the following pertinent remarks: "Before the Worthing authorities decide against the Hermite system, it would be well that a series of experiments similar to those of Dr. Piton should be carried out. Certainly a question of such vast and far-reaching importance, not only to the town of Worthing but to many other places, ought not to be decided either for or against from the results of chemical and bacteriological investigation of one or two samples. It may well be that Dr. Kelly has arrived at his conclusion too easily and too hastily; and the question is of such importance that it deserves to be definitely settled one way or the other."

Lighting of Mail Coaches.—We have, in previous issues, referred to the successful results attending the experiments made in Germany in the direction of lighting mail coaches by electricity. We now learn that the German Postmaster-General has ordered 42 new mail coaches for the night express trains. These coaches are to be electrically lighted, and Boese accumulators are to be used for this purpose. These accumulators have been in use for train-lighting for the last 12 months, and the result has been so satisfactory that the German Post Office has now decided not only to adopt Boese accumulators for all new mail coaches, but also for the old ones now undergoing repair, thus replacing the gas. Consequent upon the German Government's experience the Austrian State Railway Administration has also adopted this type of battery for train-lighting. The International Electric Company, of 55, Redcross-street, who are the sole agents for the United Kingdom and the colonies for the Boese accumulator, have during the past few months had a large sale for the battery, and the demand is daily increasing.

Tramway Congress at Cologne.—It appears from the preliminary programme issued by the Union Internationale Permanente de Tramways, that the union intends to have a grand time at the eighth general meeting to be held at Cologne in August next. The sittings of the congress will extend over eight days—probably in view of the fact that the gathering will be the eighth of the kind. The first assembly will take place at 8 p.m. on Saturday, August 18, when the members will be received at the Güzenich. On the following day an excursion will be made to Remscheid and to Barmen-Elberfeld, where the rack electric railway will be inspected. On Monday, August 20, the first general meeting will take place in the Isabel Hall at the Güzenich. On Friday, August 24, the members will be divided into two groups, one of which will visit the well-known Hoerde Steelworks and the Dortmund electric tramway, whilst the second group will inspect the Phœnix Steelworks at Laar, near Ruhrort, and the Essen electric tramway. On Saturday, August 25, the members will start for Antwerp to view the international exhibition there.

Working Instructions.—A neat and handy little volume has been issued by the Brush Electrical Engineering Company, Limited. It is entitled "Instructions for Working Plant," dealing with Brush plant, and should be found very useful by those who have the charge of such machinery. The first section deals with Mordey-Victoria alternators and transformers. A description, brief and to the point, is given of the Mordey-Victoria alternate-current system, with a diagram, and a description of the machines also appears. Then we have an account of the Brush-Vienna dynamos and motors; of the Victoria dynamos and motors; Brush dynamos and Brush-Geipel regulators; of the Brush arc lamps, direct current, series or parallel; of the Brush-Vienna arc lamp, direct or alternating current; and of engines and boilers supplied by the company. The instructions show how to fix, explain the lubrication of the machines, draw attention to the necessity for cleanliness, and generally give useful and practical information to the men employed in the machinery-house of a Brush installation. The little book should be productive of efficiency and economy in the running of stations.

Lighting of the Embankment and Bridges.—It will be remembered that on the 10th ult. the London County Council instructed the Highways Committee to consider and report on the feasibility of providing for the lighting of Westminster and Waterloo bridges by electricity apart from the question of similarly lighting the Victoria-embankment. On May 1 a petition on the subject from the North Lambeth Liberal and Radical Club was referred to that committee. Having given careful attention to this matter, the committee have come to the conclusion that, in view of the very large extra expense that the establishment of a separate installation for the two bridges would involve, it is not advisable that the course indicated in the resolution of the Council should be adopted. The committee reported further that the drawings for the generating station are approaching completion, and it is anticipated that the installation will be completed in time for the embankment and the bridges to be lighted by electricity next winter. They had still under consideration the question of the positions in which the lamp standards for the embankment shall be placed; but in the meantime the other work can be proceeded with.

Constant-Speed and Series-Wound Motor.—Mr. G. Mariotti, writing in the *Elektrotechnische Zeitschrift*, says that series-wound motors are preferable to shunt or compound wound motors wherever the load is not subject to wide variations. If, however, the load on a series-wound motor be liable to considerable reduction, there is danger of the motor racing, and then the shunt motor, or one with compound winding on the field magnets, is preferable. The author describes a method of exciting a series-wound motor,

Digitized by Google

under which the speed for all loads remains approximately constant. The method consists in supplementing the exciting current by means of a small over-compounded dynamo driven by the motor. The terminals of the auxiliary dynamo are coupled to the terminals of the field coil of the motor, and the characteristic of the dynamo is so chosen as to increase the auxiliary current when the load on the motor decreases, thereby strengthening the motor field and keeping the speed of the motor within the desired limit. To prevent reversal of polarity, due to overloading, an automatic magnetic cut-out is employed. The author gives the theory of this apparatus by means of various diagrams, and refers to a practical application of his method on a 14-h.p. motor, working on a 500-volt circuit. The output of the auxiliary dynamo in this case is 400 watts.

Energy, Current, and Candle-Power of Arc Lamps.—Mr. Frank B. Widmayer, in the New York *Electrical Engineer*, gives the following table, which shows the current required for arc lamps of the various systems of arc lighting with constant current, which will be found quite useful in an electrical repair shop, where lamps are sent in to be repaired and then readjusted. The table gives the normal current of the various systems and the so-called (trade) candle-power of the same:

Table I.—Currents in Amperes.

System.	800 c.p.	1000	1200	1600	2000	3000	4000
Ball	4·	—	6·&6·4	8	10·	15·	—
Edison (Sperry)	—	—	6·4	—	10·	—	—
Easton	—	—	6·	8·	10·	—	—
Brush	—	—	6·4	—	9·6	15·	20
Thomson-Houston	—	5·	6·8	—	10·	15·	—
Western Electric	—	—	—	—	9·6	—	—
Clark	—	—	—	—	9·8	—	—
Schuyler	—	—	—	—	9·5	—	—
U. S. Old / Western Electric (low-tension)	—	—	—	—	18·	—	—
Excelsior	—	—	—	—	10·	—	—
New Wood or Ft. Wayne	4·2	—	6·8	—	9·5	—	—

Table II.—Candle-Power.

So-called candle-power.	Watts per lamp.
2,000	450 to 500
1,600	384 to 416
1,200	278 to 310
800	200 to 226

The second table shows the number of watts consumed by lamps of various systems and their relation to the so-called candle-power; these results were obtained from a number of readings, and the averages are given in the tables.

Automatic Regulator for Dynamos.—We have received a circular referring to Conrady's automatic regulator for dynamos. The regulator comprises a solenoid, the core of which operates a reversing friction clutch to which power is supplied mechanically. The solenoid has only to put the friction clutch into or out of gear, and it therefore absorbs only a negligible amount of current, being from 5 to 30 watts. The power required for operating the regulating means being supplied from a separate source, may be made of any required amount without interfering with the prompt and accurate action of the regulator. This regulator may thus be adapted to operate either a variable resistance, or the brush-holder of a series dynamo, or the throttle-valve or expansion gear of the steam or other motor driving the dynamo, or any other means of regulation. This regulator is made by Messrs. Conrady and Co., of Keighley, the London agents of whom are the Indestructible Ignition Tube Syndicate, of 100c, Queen Victoria-street, E.C. This regulator is made to control all systems of electric supply. The principal cases are for constant-current supply, constant-potential supply, and supply by several dynamos working in parallel. It is claimed that these regulators will keep the dynamos controlled by them within 1 per cent. of the required normal condition (current or voltage). For ordinary work, regulators, either series or shunt wound, are furnished, and operating regulating resistances capable of absorbing up to 200 watts.

A Transmission Dynamometer.—Dr. Louis Duncan describes in the *Electrical World* a transmission dynamometer which has been found useful for some special experiments for a number of years. He says: "I have used an absorption dynamometer consisting of a copper disc rotating in a magnetic field. The power was calculated from the pull on the magnet and the speed of the disc. The heat was absorbed by water running through the apparatus. This dynamometer is of a rather limited range, unless belting is resorted to. For the purpose of trying some experiments on the efficiency of air propellers, a transmission dynamometer was designed on somewhat the same principle. It consisted of a copper disc fastened to the propeller to be rotated and placed in the field of a rotating electromagnet. The apparatus was calibrated by turning the magnet at known speeds and measuring the pull of the disc, which was kept stationary. After this, to measure the power transmitted, it is simply necessary to know the speeds of the field magnets and the copper disc, and the pull is proportional to the difference of the speeds, and can be obtained from the calibration curve. The disc is so constructed that it can be cooled by allowing water to flow on it in such a manner as not to absorb power, and a temperature correction can be applied if necessary. The speed of the disc can be regulated by varying the speed of the magnets and the strength of the magnetic field. In this way power can be transmitted without the intervention of any belt or gearing, and it forms an exceedingly convenient apparatus for some purposes."

Technical Education in London.—The Technical Education Board of the London County Council propose to hold, with a view to promoting a better understanding of the needs and desires of the various trades in the matter of technical education, during the months of June and July, a series of public conferences between the representatives of the principal London industries. It is hoped by a free and practical discussion among those actually concerned in industry to elicit useful information as to what kind of technical education is required in each case, in what way the existing provision is defective, how it can be rendered more efficient, and what steps can be taken to bring it to the notice of the young workman or the apprentice. Each conference will be strictly confined to representative practical men belonging to one particular group of trades. Every trade union belonging to the group will be asked to nominate delegates. Every employers association will be similarly invited. The London Chamber of Commerce and the London Trades Council will also be asked to designate other representative employers and workmen. The meetings will take place probably at the County Hall, Spring-gardens. The first meeting will be devoted to the building and furniture trades. The three subsequent meetings will follow at fortnightly intervals, and will deal respectively with the engineering, shipbuilding, and metal trades; the book, paper, and printing trades; and the clothing, leather, and miscellaneous trades. The names and addresses of representatives should be sent at once to the Secretary of the Technical Education Board, 13, Spring-gardens, S.W., from whom any further information can be obtained.

Submarine Telegraphy.—Our contemporary *Commerce* in its last issue says: "Much has yet to be done before the world can boast that it is served either as effectively or as cheaply as it ought to be in the way of cable communication. Particularly is this the case with outlying portions of our empire. Heartily glad are we to see that in South Africa, as in Australasia, the business

Digitized by Google

men to whom the ocean lines are invaluable are pushing forward with an agitation for a cheaper, if not a better, cable service. The great initial expense of laying these submarine lines is, no doubt, a serious obstacle. But the conveniences they offer to individuals, as well as to Governments in times of peace, immense as they are, sink into insignificance compared with their value, if thoughtfully planned and laid, to any great Power in war time. On no country more than on our own is it incumbent to establish these adjuncts to the defensive forces; whilst the keen commercial rivalry of the industrial nations impels each to seek for and to use the speediest and most effective means of communication with their *clientèle*. In spite of the heavy costs incurred in the installation and in the maintenance of their lines, the Eastern Telegraph Company is able to distribute a very satisfactory dividend to its shareholders. Under the guidance of Sir John Pender—who, when he is the only Richmond in the field, knows better than most men how to drive a bargain—that company has been able to obtain much larger subventions from Governments than the future will permit. Present contracts have to be respected, but, at the Cape, the expiry five years hence of the arrangement with the Eastern Telegraph Company is eagerly awaited, when, as Sir Gordon Sprigg has declared, the Government will have the whip-hand of the company, instead of the company, as at present, having the whip-hand of the Government."

Three-Phase System in Austria.—A small central station on the three-phase system has recently been established at Erding, an Austrian town of some 3,000 inhabitants. The generating station is situated about two miles from the town, the motive power being obtained from the River Sempt. A horizontal turbine, supplied by the Augsburg Engineering Works, develops 60 h.p. at a speed of 35 revolutions, and by means of countershafting, pulleys, and belting two dynamos of nominally 40 kilowatts are driven at 750 revolutions. These alternators are direct coupled to the exciters. The exciting current is brought to the inductor by means of rings upon which the brushes press. The alternator produces a difference of potential of 1,500 volts, and a maximum current of 15 amperes in each circuit at a frequency of 50 periods per second; the exciter gives current at 60 volts. A single alternator absorbs the whole power of the turbine. Leaving the alternator, the current is led by means of three cables to the distributing-board. Passing from the station, the current is conveyed by three wires to Erding. Here the high-tension circuit feeds five transformers. The secondary circuits are connected in quantity, and form the distributing circuit. The conductors passing out of the generating station are of bare copper enclosed in glass tubes, and they are afterwards fixed to oil insulators carried on masts 40ft. high, of which there are 81, arranged at intervals of 130ft. Special arrangements have been adopted to prevent accidents from atmospheric changes. For instance, a metallic point in connection with the earth has been fixed at the top of 16 masts, being one in every five. A lightning protector has also been erected. It is formed of two carbon plates, one being a short distance from the other. The upper plate has an iron core movable in a solenoid. The wires of this solenoid lead respectively to the iron core on the one hand, and to the earth on the other. The second plate is connected to the conductors. If an atmospheric discharge takes place, an arc is set up between the two plates, and the circuit is closed through the earth. But as the iron core is attracted the arc is abruptly broken. Similar lightning conductors have been fixed in 15 parts of the secondary network. The streets are lighted by 97 16-c.p. lamps and six 12-ampere arc lamps, and altogether 600 lamps are supplied in the town, besides a few electric motors.

The Electrical Trade Section.—A meeting of some importance to the electric traction industry was held on Friday last at the London Chamber of Commerce, when the Electrical Trade Section was summoned to discuss the provisions of the Locomotive Acts in relation to electric conveyances. The chair was taken in the first instance by Mr. R. Percy Sellon, in the temporary absence of Major Flood-Page. The secretary of the Chamber, Mr. Kenric Murray, read a letter which had been received from the Chief Commissioner of Police regarding the position of the Metropolitan police authorities towards the use of omnibuses and similar conveyances on public streets worked by electric motors, and explained that some recent experiments with driving an electric postal van through the crowded City streets had provoked a letter to the *Times*, raising the question as to whether such vehicles do not come under the Locomotive Acts of 1861, *et seq.* In consequence of this letter, the Chamber had written to Scotland Yard for an official opinion upon the subject, and, in reply, were informed that counsel had advised the Chief Commissioner on the point, to the effect that all vehicles *driven by other than animal power* must be construed to come within the Act. Considerable discussion ensued upon this point, and various suggestions were made. Mr. Sydney Morse proposed that the Chamber should—with the kindly help of the Board of Trade — bring in a Bill to amend the Act so as to allow the use of electrically-driven conveyances on the streets. Mr. Trotter asked whether previous opinions from the police had not been the direct converse of those now stated. Mr. Sellon thought, in the first place, that the initiative of action might be left to those more particularly interested, and these were, he thought, at present very few. A test action might be brought, and the matter decided in court. Obviously, the question turned upon the definition of "locomotive" in the Acts, and equally obviously these, when framed, had never contemplated the use of electrically-propelled vehicles. Major Flood-Page assured the meeting that considerable advance in the development of electric traction on streets would take place within the next year or so, and it was therefore of great importance that the disputed point should be settled as soon as possible; also that the influence of the Chamber would be of service in obtaining a favourable issue. It was therefore resolved finally that a letter should be sent from the Chamber to the Board of Trade asking that Department to move in the matter to the extent of promoting an Act to amend those in question, leaving it at the same time to those persons more particularly interested in the development of electric traction on this plan to obtain an interim decision under the Acts—probably favourable—by means of a test case in the law courts. The remainder of the meeting was occupied with a brief discussion upon the rating of electrical works. Mr. Morse gave details of the excessive revaluations of conduits, pipes, and mains laid down in connection with central-station work, the base underlying such valuation being apparently that of the hypothetical tenant. In one case the excessive valuation meant a difference of 1 to 1½ per cent. in the dividend. It was resolved in the end to have an early meeting of the section, and then to appoint a special committee to deal with this matter. Meantime every effort is being made to secure, on behalf of electrical interests, the united action which will effect the desired result more quickly and readily than isolated objection.

The Coatbridge Central Station.—General Arrangement o the Works

Digitized by Google

THE COATBRIDGE CENTRAL STATION.

We give herewith an illustration which shows in plan and elevation the general arrangement of the Coatbridge central station of the Scottish House-to-House Electricity Company, Limited, and which has been equipped by the Brush Electrical Engineering Company, Limited. As a full description of this station was published in the *Electrical Engineer* of the 6th April, it will only now be necessary for us to refer our readers to that issue for the details of the plant and method of distribution.

THE STANSERHORN ELECTRIC RAILWAY.

This line, which was opened last August, has operated successfully for the intervening period; and details of its construction and working were lately brought forward before the Société des Ingénieurs Civils of France, to show the possibilities and advantages of such a system as that employed. The line was undertaken by Messrs. Bücherer and Dürrer—a firm of Swiss engineers—who also promoted and built the Bürgenstock and the Genoa tramways: and it has a number of interesting features which give it prominence amongt mountain railways. The Stanserhorn mountain rears itself to a height of nearly 6,000ft. from sea-level, being, therefore, a little higher than the Righi, but less than Mont Pilatus. The town of Stans is situated at its feet, and from the summit a magnificent view is obtained over the whole of the Bernese Alps, the lake of the Four Forest Cantons, and the northern parts of Switzerland generally. Means of access to this point are numerous and easy: steamers run from Lucerne to Stanstadt in half an hour, and thence the traveller is carried on an electric tramway to Stans. The latter journey only occupies some 15 minutes. At Stans is the terminus of the funicular or cable railway, by means of which the mountain itself is ascended. Both tramway and cable line are operated by means of electric energy from the same generating station.

The difference in levels surmounted by the cable line is about 4,200ft., whilst the length of line is not more than 2½ miles. This rise would be perhaps too great for a simple funicular railway, especially as the route necessary to be followed involved a number of heavy reverse curves, besides using at certain points the bed of a mountain torrent. It was therefore decided to split up the line into three distinct sections, transferring the passengers at the two intermediate stations.

The first section—that from Stans to Koelti—ascends to a level of 800ft. or so above the terminus at the former place: the length of line is nearly a mile, and the grades vary from 12 to 27·5 per cent. The second section—from Koelti to Blumatt—has much steeper gradients, since in a length of 1,200 yards it rises over a height of 1,500ft., the grades being from 40 to 60 per cent. The third section is equally steep: the total rise is about 1,900ft. upon a length of line equal to some 1,400 yards, with similar grades to the last. On this portion also there is a tunnel 150 yards long, and a viaduct of equal length. The upper terminus is close to the Hotel Stanserhorn, from which a pathway leads to the actual summit of the mountain, 150ft. higher.

Each section of the cable line is composed of a single track, with a pass-by in the centre of its length. Two carriages are employed on each, connected to the ends of a wire rope which is wound upon a drum by means of an electric motor, fixed at the top of the section.

Electric energy for operating these cars is obtained from a water-power station situated at Buochs, 3½ miles distant, where a convenient fall is employed to drive turbines and dynamos. In case any possible accident should happen to the hydraulic machinery, and lest the water supply should fail, a steam-engine of 60 h.p. is provided at each winding station to serve as a stand-by. The cars are built with seats in tiers; they have each four compartments to hold eight persons, and, with the same number on the platform, there is a total accommodation for 40 passengers per car.

Probably the most important feature for consideration in planning a line of this kind would be the particular type of brake to employ, not only for checking the speed under ordinary circumstances, but also to hold the cars in case of a break away. With most mountain lines of any length or curvature it is found much the best and safest plan to use a rack rail, so that absolute stoppage of the car upon any grade at any point may always be ensured, if necessary, by locking the wheels. On the Stanserhorn line, however, the safety brakes come into action automatically as soon as the tension of the rope is released, just as in hydraulic lifts and elevators. The car wheels actuate another wheel, which works a screw and slide blocks in such manner as to grip the rails firmly enough to hold the car, even on a 60 per cent. grade. A special section of Vignoles rail is used for this purpose, and a pressure of 10 tons, it is claimed, can be exerted upon the rails by each of the two pairs of brake grips. A third pair is also provided for working from the platform as a hand-brake.

The terminal stations of each cable section are brought close to one another, so that passengers only require to traverse a few steps in passing from one to the other. In order to ensure the simultaneous arrival of the cars at the respective termini, the time occupied in ascending and descending each section is kept the same, irrespective of distance, and the speeds of travel are, therefore different. Thirteen minutes are found sufficient to give an average speed of 100ft. per minute—vertical lift—on each section, the entire journey on the cable line occupying 45 minutes, with an allowance for transfers at the two intermediate stations. This equals a speed of from 3½ to 4½ miles an hour—not, perhaps, very excessive—but still quite enough on such steep grades. It is, by the way, an extremely interesting fact to remember that the speed, although apparently so slow, yet consumes no more time absolutely in rising to the height mentioned than would be taken by trains running at 40 miles an hour on an ordinary railway laid out with sufficient length to reach the same altitude on maximum grades of 3 per cent.; or 20 miles an hour on 6 per cent. grades. The journey from Lucerne to the Hotel Stanserhorn is accomplished in 1½ hours, at a charge of 7s. return fare, and there is a regular service of 10 trains daily.

GAS UNDERTAKINGS IN RELATION TO THE USE OF GAS-ENGINES.*

BY H. LEES, HEXHAM.

When asked by the president to contribute a paper to the *Proceedings* of this association, I had some misgivings as to being able to deal with a subject that had not already been fully discussed by this or kindred associations. The selection ultimately made suggested itself to me on thinking over the papers and discussions at the meeting of the Incorporated Gas Institute, held at Belfast in June of last year.

It will be in the minds of many who were present at that meeting that the question of gas-engines for driving exhausters was introduced into the discussion on Mr. Bryan Donkin's paper on "Rotary Engines"; and that it was suggested by Mr. Emerson Dowson, in his paper on "Gas Power," that the managers of gas undertakings were not alive to their own interests in the attitude adopted in regard to the gas-engine. This, however, was not allowed to pass unchallenged; and enough was said to indicate that it was more than possible the opinion had been formed on insufficient evidence. To judge from isolated cases, it would be easy to get up a very strong indictment against us; while it would be quite as easy to put forth more than ample defence, by selecting a case where considerable enterprise was shown in that direction. Neither of these extremes would be a true statement of the facts; and in all probability, if we take the "happy medium," we shall be near the mark.

By the courtesy of the members of this association, I am enabled to give particulars of what is being done in the

* Paper read before the North of England Gas Managers' Association.

Digitized by Google

use of gas-engines in the district comprised within the limits of the association. A reference to the appendix will show that out of 30 undertakings dealt with, gas-engines are used at 10. This is a proportion of 33⅓ per cent., as against 12½ per cent. stated by Mr. Dowson as the proportion for the United Kingdom. It is possible that the proportion in this district may be higher than in other parts of the kingdom; but it is difficult to give any special reason why this should be so. Where coal or coke is more expensive, the gas-engine should be in greater demand. The number of works at which gas-engines are used is not large, and it is more than probable an extension in that direction would be beneficial to some who might participate in it.

In some instances, it may be possible to show that steam is cheaper than gas even on a gasworks. But at present it is my intention to put the case for the gas-engine before you; and in doing so I have to acknowledge my indebtedness to several gentlemen who have favoured me with the benefit of their experience, which strongly confirms my own. The 2-h.p. (nominal) gas-engine in use at the Hexham Gasworks has been working constantly night and day—with short stoppages for cleaning and repairs—during the past 10 years. This is equal to a life of 30 years compared to an engine in use during the working hours of most industrial establishments. In addition to driving the exhauster, two pumps are in constant use for pumping water and ammoniacal liquor respectively. It will be understood that an engine 10 years old is not likely to be so economical as the modern gas-engine, and therefore the results in this respect are not the most favourable that could be given. The consumption of gas during the past 12 months was 366,700 cubic feet, or 42 cubic feet per hour. The cost of gas delivered into the holder may be taken at 11d. per 1,000 cubic feet. This makes a total cost of gas for the year of £16. 16s., or 0·46d. per hour. The total cost of repairs for the 10 years the engine has been in use is £25, or £2. 10s. per annum. This brings the annual cost for gas and repairs to £19. 6s., or 0·53d. per hour. The cost per 1,000 cubic feet of gas made is 0·196d. No allowance has been made for oil, etc., as in any comparison with the use of a steam-engine, this item would presumably be about the same in each case.

It would perhaps be difficult to work at a less cost than this for fuel of any other character, apart from the extra labour involved in the use of solid fuel. It may be argued that there need be no extra cost for labour on a gasworks, as the stokers could attend to the boiler. There is, however, a limit to which you can go in putting extra work on the stoker. In the case under consideration, it would not be conducive to good work to put this extra labour upon him. It may therefore be assumed that the cost of labour alone, in substituting steam for gas, would in many cases exceed the cost of gas, to say nothing of the value of fuel used.

What may be taken as a fair comparison between gas and steam is shown in the following table, based upon statistics given by Herr C. Korte in a paper read before the Association of German Engineers about two years ago. The figures contained in the table are calculated upon a working day of 10 hours; and the cost appears to include interest on capital as well as all working expenses. The price of coal taken may seem high. But it is not more than is frequently paid in this district for best steam coal; and we may reasonably assume that if an inferior quality was used, more would be required, and the cost would not be reduced.

TABLE I.—Comparative Cost of Small Gas and Steam Engines per Horse-power per Hour.

Gas per 1,000 cubic feet.	*Gas-engines.* ½ h.p.	1 h.p.	2 h.p.	3 h.p.	4 h.p.	6 h.p.
3s. 4d. ...	4·08d.	2·64d.	2·28d.	2·04d.	1·92d.	1·80d.
2 10 ...	3·72	2·40	2·03	1·80	1·68	1·56
2 6 ...	3·52	2·26	1·90	1·66	1·55	1·43
2 3 ...	3·37	2·15	1·79	1·55	1·46	1·34
2 0 ...	3·23	2·05	1·69	1·45	1·37	1·25
1 9 ...	3·08	1·94	1·58	1·34	1·27	1·15
1 6 ...	2·93	1·84	1·48	1·24	1·18	1·06
1 3 ...	2·78	1·73	1·37	1·13	1·08	0·96
1 0 ...	2·64	1·62	1·26	1·02	0·99	0·87
0 9 ...	2·49	1·52	1·16	0·92	0·89	0·77
Coal per ton.		*Steam-engines.*				
12 6 ...	—	2·88	2·04	1·68	1·44	1·32

It will be seen from these statistics that where the cost of gas does not exceed 2s. 3d. per 1,000 cubic feet, it will compete favourably with coal as regards power supplied, with engines of 4 h.p. and 6 h.p., and at higher prices in the case of smaller engines. We are, moreover, led to believe that these are not the best results that have been obtained with the gas-engine, as Mr. Dowson states in his paper previously referred to that "the makers of gas-engines are obliged to admit that, when town gas costs more than 3s. per 1,000 cubic feet, the working cost of an engine of more than 14 h.p. nominal exceeds that of a steam-engine of the same power under the same conditions of working."

The case for the gas-engine has, therefore, not been exaggerated; and when it becomes a question of getting gas at the cost delivered into the holder, the comparison is very decidedly in favour of gas. There are, however, further considerations which apply to gasworks. Coke is generally used for boilers. The value of this depends upon the local demand; and without there being any difference in the quality, it is possible a considerable difference in price may rule as between one district and another. Of recent years, by the introduction of "forced draught," the gasworks manager has been enabled to use breeze and more inferior fuel produced on his works, and which in some cases it was an expense to dispose of. It is not, however, in small works where these conditions are likely to exist to such an extent as to materially affect the cost of steam power, and it is in these that gas-engines are most useful and economical.

The use of steam appeals to us also on other grounds than that of cost, and so strong is the conviction of some that it is indispensable on a gasworks, that the question of cost would have but scant consideration. It has its uses, no doubt, and it is perhaps not too much to say that it has its "mis-uses," to which it is often applied. It is not an uncommon thing to steam out exhausters, condensers, washers, etc., and under certain circumstances this may be expedient. But is it not a practice that for many reasons should be deprecated? The knowledge that steam can be applied to these purposes often leads to the neglect of the application of means which would prevent the necessity for its use. Steam is very useful in preventing the water in the cups of gasholders from freezing; but supposing it is requisite for this and other purposes, is it wise to have a steam-boiler at work all the year round on the chance of being required two or three times during the winter, when, by the use of gas, the motive power of the works could be provided at considerably less cost? If steam is a necessity, it would be more economical in many cases to keep a small boiler in readiness for such cases.

Perhaps something should be said upon the supposed difficulties of gas-engine when applied to exhausters. It is sometimes argued that it is not possible to regulate a gas-engine to meet the fluctuations of the make of gas, so as to keep a level gauge. My experience has not been of that unfavourable character. This can be accomplished by the governor of the engine, and the usual method of by-passing; the difference between the summer and winter make being dealt with by using drums of different sizes on the exhauster shaft. It is urged that a gas-engine on a gasworks is an advertisement, and in small towns this doubtless is so. If we have faith in the use of gas-engines, we should not be afraid to show it by adopting their use where we possibly can on our own works. Having done this, we are free to recommend them to others, and this opportunity occasionally comes in our way. Mr. J. Whimster, of Armagh, who takes a great interest in the application of gas motors on small works, informs me that most of the engines introduced into his town are the result of his having called attention to the one in use at his works; and recently a 20-h.p. engine, consuming nearly one million cubic feet of gas per annum, was added to the list—directly through an investigation into the working of his own engine.

The appendix shows that the largest percentage—so far as returns are obtainable—of gas used for motive power in any town or district in the list is 4·46 of the total quantity consumed. This amount is small, and if (as we are sometimes reminded) the future of gas lies in the direction of its utility for other purposes than lighting, we may conclude

APPENDIX TO MR. H. LEES'S PAPER ON "GAS UNDERTAKINGS IN RELATION TO THE USE OF GAS-ENGINES."

STATISTICS HAVING REFERENCE TO GAS UNDERTAKINGS WITHIN THE DISTRICT OF THE NORTH OF ENGLAND GAS MANAGERS' ASSOCIATION.

Number corresponding to name of undertaking.	Annual consumption of gas. Cubic feet.	Gas consumed per annum by gas-engines (exclusive of works use). Cubic feet.	Gas consumed by gas-engines per cent. on total consumption.	Number of gas-engines in use.	Price of gas for lighting purposes. Per 1,000 cubic feet.	Price of gas for gas-engines.	Special facilities offered for encouraging the use of gas as a motive power.	Gas-engine used on works.
1	4,000,000	nil.	nil.	nil.	3s. 5d. and 3s. 9d.	—	—	½-h.p. gas-engine for driving exhauster and pumps.
2	4,500,000	,,	,,	,,	4s. 2d. and 5s.	,,	—	No machinery.
3	10,000,000	15,000	0·15	2	3s. 3d.	Same as for lighting.	—	One gas-engine for driving exhauster and pumps.
4	12,000,000	120,000	1·00	2	3s.	,,	—	No machinery.
5	13,788,700	411,200	2·98	8	3s. 7d.	3s. 1d.	—	—
6	16,000,000	113,000	0·70	5	3s. 6d.	Same as for lighting.	—	—
7	21,000,000	100,000	0·47	6	3s. 6d.	,,	—	—
8	22,000,000	876,200	3·98	9	2s. 8d. to 3s., according to consumption.	,,	—	2-h.p. gas-engine for driving exhauster and pumps.
9	22,000,000	200,000	0·91	4	3s. 6d.	,,	—	—
10	23,005,000	1,032,000	4·46	14	3s. 3d. and 3s. 4d.	,,	—	—
11	25,000,000	495,000	1·98	8	4s. 1d.	,,	—	—
12	28,000,000	348,000	1·24	12	3s. 1d. to 3s. 5d., according to consumption.	3s., subject to 5 and 10 per cent. discount, according to consumption.	—	—
13	30,323,900	411,500	1·35	11	4s.	3s.	Meters free for gas-engines.	—
14	32,750,000	1,170,000	3·57	10	3s. 3d.	Same as for lighting.	—	—
15	34,500,000	1,373,700	3·98	14	3s.	For small engines, 2s. 6d.; 6 h.p. and upwards, 2s. 3d.	Lower rates for specially large engines. Free service pipes.	Gas-engines for driving exhauster, pumps, and oxide elevator.
16	35,000,000	nil.	nil.	nil.	2s. 6d. to 3s. 2d.	—	—	—
17	38,000,000	700,000	1·84	8	3s. 4d.	Same as for lighting.	—	—
18	43,595,000	377,000	0·87	9	3s. 4d.	,,	—	One gas-engine for duplicate exhauster.
19	80,500,000	1,847,700	2·29	13	2s. 8d. and 2s. 11d.	,,	—	—
20	120,000,000	1,000,000	0·83	25	2s. 6d.	2s. 4½d. and 2s. 3d., according to consumption.	Service pipe and meter free, and half cost of fixing.	Two 6-h.p. engines lifting coal from barges into retort-houses.
21	180,000,000	2,860,000	1·59	34	2s.	Same as for lighting.	—	—
22	200,000,000	Not recorded separately.	—	35	2s. 3d., less 5 per cent. discount.	,,	—	—
23	220,000,000	3,172,700	1·44	44	2s. 3d.	,,	Gas-engines let on hire; inspected free every three months by arrangement.	—
24	246,500,000	8,500,000	3·44	63	2s. 4½d.	,,	Easy terms of payment, fixing, etc. Undertake repairs and supervision of gas-engines.	Gas-engines used for blowing, and for driving the whole of the machinery of the fitting shops.
25	300,000,000	Not recorded separately.	—	about 30	2s.	,,	—	—
26	330,000,000	About 10,000,000	3·03	about 40	2s.	,,	—	—
27	350,000,000	Not recorded separately.	—	60 to 70	2s., 2s. 1d., and 2s. 3d., according to consumption.	,,	Sell and fix gas-engines and lay services for nominal profits, according to probable consumption.	—
28	399,258,000	,,	—	25	2s. 6d., less 7½, 10, 15, and 20 per cent., ditto.	,,	Service pipe laid free of charge.	One gas-engine for pumping water from the river.
29	646,000,000	,,	—	183	1s. 6d. to 1s. 11d., according to consumption.	,,	—	One 6-h.p. gas-engine driving 35,000 cubic feet per hour exhauster.
30	1,700,917,000	,,	—	305	1s. 10d., less 10 per cent. discount, and 5 per cent. extra discount to consumers of 400,000 cubic feet and upwards per quarter.	,,	—	Two 7 h.p., one 4 h.p., and one 1 h.p., used for driving smiths' blasts, circular saw, drilling-machines, tar and liquor pumps, &c.

Digitized by Google

that we have a very wide field before us. Some of us, however, think we are not to be deprived of all the lighting; and so we are disposed to take a very hopeful view of future prospects. But it is no use to live in a "fool's paradise." While we believe there is a great future for gas, we also acknowledge that its attainment depends greatly upon the efforts of those who are responsible for the administration of gas undertakings, and the education of consumers. The latter is probably of greater importance than the former, and generally it falls upon the manager of a gasworks to undertake that work in addition to his already multifarious duties.

It would be difficult to lay down fixed lines upon which to work with a view to increasing the consumption of gas for motive power. Where the price of gas is as low as 2s. and 1s. 6d. per 1,000 cubic feet, one would naturally conclude that this was sufficient inducement to secure any consumption that it would be possible to get by means of concessions. Something, however, is being done to assist in various ways this branch of our business. On a further reference to the appendix, it will be seen that in one town gas-engines are let out on hire and inspected free; in another, easy terms of payment are allowed in the purchase of engine, cost of fixing, etc., and supervision is undertaken in this case also; while in a third, they sell and fix engines for nominal profits. Five undertakings make a special allowance in the price of gas used for gas-engines; and many others allow extra discounts on the basis of consumption. It has already been shown that, for small-power engines, gas is cheaper than steam when in constant work. Where the work is intermittent, the advantage is considerably increased; and instances have doubtless come within the experience of most of us where the cost of gas has not reached the amount previously paid in fireman's wages. One of the most recent developments in the use of the gas-engine is in providing power for electric lighting installations. Mr. Dowson has dealt very ably with this subject in a paper read before the Institution of Civil Engineers; and whilst his advocacy had more particular reference to the use of fuel gas, some very interesting and encouraging figures were published in regard to the use of coal gas. The case of the Morecambe electric lighting installation has done service on more than one occasion, and is still capable of being used in a most favourable light for gas as compared to steam. The statistics published in relation to it in Mr. Dowson's paper are the result of working trials made by Messrs. Andrew and Preece, electrical engineers, of Bradford. The following is one of two trials made with town gas at 3s. 3d. per 1,000 cubic feet:

Cost of gas per kilowatt	1·555d.
Cost of labour per kilowatt	0·400d.
Cost of oil and waste per kilowatt	0·013d.
Cost of water per kilowatt	0·035d.
Total cost per kilowatt	2·003d.

The following table gives a comparison of what the cost would be with gas at various prices, and under similar conditions of working in other respects; also showing the cost exclusive of labour:

TABLE II.—Cost of Generating Electricity by Gas-engines on the Basis of the Morecambe Experiment with Gas at Various Prices, Inclusive and Exclusive of Labour.

Price of gas per 1,000 C. feet.	Cost per kilowatt, inclusive of labour.	Cost per kilowatt, exclusive of labour.
s. d.	d.	d.
3 3	2·003	1·603
3 0	1·883	1·483
2 9	1·764	1·364
2 6	1·664	1·244
2 3	1·524	1·124
2 0	1·405	1·005
1 9	1·285	0·885
1 6	1·165	0·765

These figures become still more interesting when placed alongside published statistics of the working of electric lighting undertakings having statutory powers in the United Kingdom. The cost for coal, oil, waste, water, and engine-room stores (exclusive of labour) is shown in Table III. for the companies named.

These costs are exclusive of all labour, and it would only be fair to allow for the cost of firing the boilers when comparing with the gas-engine. This is not published separately, but I am able (through the courtesy of the manager of one of the companies named) to give the cost in their case. It works out to 0·25d. per kilowatt. Taking this as an average cost, and adding it to the above figures, a comparison then shows that with gas at 2s. 3d. per 1,000 cubic feet it will compete in regard to cost with the most favourable working of the companies named; and up to 3s. 3d. per 1,000 cubic feet, it is more economical than the average working of electric lighting companies' stations where steam is the motive power.

TABLE III.—Cost of Generating Electricity by Steam Power (Exclusive of Labour) at the Electric Lighting Works Named.

Name of company.	Cost per kilowatt, exclusive of labour.
Westminster	1·29d.
Birmingham	1·16d.
Liverpool	0·88d.
Chelsea	2·22d.
St. Pancras	1·91d.
Newcastle and District	1·50d.
Newcastle-on-Tyne	0·97d.
City of London	2·34d.
House-to-House	2·80d.
Eastbourne	1·93d.
Metropolitan	2·05d.
St. James's	1·06d.

I must confess that when I entered upon the work of collecting information for this paper I was not prepared for any such results, and they are not now advanced as being final. But the conclusions suggested are worthy of consideration on the part of those who may have opportunities of going further into the matter. The Morecambe results were obtained on a comparatively small scale, and in that respect they might be supposed to be at a disadvantage. The working of steam-engines in electric lighting works will doubtless be more costly than in works where a continuous run of nine or ten hours per day takes place, and the comparison with establishments of this character would be less favourable to gas where large powers were required. It is difficult to obtain the necessary information upon which to base such comparison; but from particulars I have been able to collect, though not in a form to make accurate comparison, there is no doubt the use of gas as motive power is making great strides. All who are in any way responsible for the administration of gas undertakings should aim at still further encouraging this; and I think most of us are anxious to help it on as far as we possibly can. But we have other consumers to take into consideration. There are gas-engines that do not consume more than the artisan does for lighting his cottage, and it would be unfair to make a special reduction in such cases. The same principle applies up to the point at which the gas-engine exceeds the consumption of the largest consumer for other purposes. If a concession is to be made in price, the most satisfactory method appears to be to regulate it by the quantity consumed, and in this way we shall probably secure all the consumers of this class that are to be obtained at all. Other methods may appear expedient and justifiable under certain circumstances, but speaking generally this will meet the case.

It is perhaps not too much to claim that we are continually on the look-out for any possible means of increasing the consumption of gas, and may we not now ask the more practical co-operation of gas-engine makers? That the price of the engine does more to retard an extension of its use than does the price of gas, has been borne out in the experience of many who have had the question to deal with. There have been reductions recently, and the demand has increased concurrently. Still, to outsiders it does seem possible to yet further reduce the prices. We may also reasonably expect further improvements in the construction of the gas-engine. The advances that have been made encourage this expectation; and when some of the drawbacks attributed to the use of the engine for certain purposes have been removed, and it is brought more on a parallel with the most perfect form of steam-engine, we may hope to share in some of the benefits that will accrue.

Paris.—It is proposed to light the Hospice d'Ivry electrically. Gas and oil have been used hitherto. A report has been presented on the subject by M. Davrillé des Essards.

COMBINED DIRECT AND ALTERNATING CURRENT GENERATOR.

Two generators of a new type have recently been completed by the Westinghouse Electric and Manufacturing Company at the station of the Citizens' Light and Power Company, at Rochester, N.Y. These machines apparently mark the beginning of a new departure in station operation. These two generators, which are exact duplicates, are the first of the type built, and the success in their operation is so marked that they seem to be worthy of more than passing notice.

In the absence of a more specific trade name, the machine, according to the *Electrical World*, from which we abstract the following, may be called a combined direct-current and alternating-current generator. The peculiarity of this combination is that a direct current of 550 volts is taken from one end of the armature shaft and an alternating current of about 385 volts is taken from the opposite end of the shaft. In other words, the entire output of the generator may be utilised for direct-current work, the entire output used for alternating-current lighting and power purposes, or it may be divided between the two classes of work, in such proportions as may be desired.

The first impression produced by the new generator is its extreme simplicity of construction. The armature, which is essentially the same as the ordinary type of Westinghouse single-wound iron-clad armature for street railway generators, revolves in an eight-pole field. It revolves at a speed of only 750 revolutions per minute, giving a frequency of 6,000 alternations per minute on the alternating side. The direct-current end of the shaft is fitted with an ordinary commutator.

So far as the direct function of the generator is concerned, no explanation is necessary. The current is commutated in the usual manner, and does its work with indifference to the somewhat peculiar condition of affairs existing at the other end of the armature shaft. The alternating-current side of the generator is arranged on the two-phase system: two alternating currents are delivered on two separate circuits, with a quarter-phase difference, thus enabling alternating motors to start with good torque.

The alternating-current connection is made thus. The armature has a hollow core; the wires of the two-phase alternating circuits are given positive and negative connection to the commutator on the direct end of the shaft, the wires making suitable connections to collector rings on the alternate-current end of the shaft. Thus, while the current is commutated and sent out from what may be called the direct end of the shaft, the alternating currents are carried to the other end, and pass through the step-up transformers on to the line, with the voltage increased to 2,000. The wires passing through the hollow core of the armature are bolted in the proper position to the back of the commutator.

The fact that there is a voltage of only 385 at the alternating end and a voltage of 550 at the direct end seems to be a little perplexing. Possibly it is made a little clearer by the fact that in separate generators a direct E.M.F. is rated at its maximum, and an alternating E.M.F. is rated at the average of the curve, say, seven-tenths; and obviously, the same rating must obtain when the different currents are combined in the novel way described above. The two-phase four-wire systems are utilised in this combined generator, and it is sufficient for the present to record the fact that all difficulty of equalising the voltage on the circuit is obviated; in other words, it has been demonstrated that absolutely no balancing is necessary—a fact which will be duly appreciated.

It should be noted that while the combined generator does all kinds of work except series arc lighting the alternating feature gives all the advantage of transmission of current, besides bringing into use the important feature of self-starting alternating motors. It will be understood that, under these conditions, the generator is capable of work on the following lines: direct-current motor work; incandescent lighting by alternating current; alternating-current motor work; alternating-current arc lighting; street railway work. It is, of course, unnecessary to occupy space in pointing out the advantages to a medium-sized station, running night and day, on the various classes of work which have been enumerated, and the distribution of load from one end of the shaft to the other, at will, without shutting down. Another element must not be lost sight of, and that is the safety of operators at the station secured by the low voltage. The alternating current goes to the transformer with a voltage of only 385—a fact which tells its own story.

ELECTRICITY AS A MOTIVE POWER IN THE IRON AND STEEL INDUSTRIES.*

BY D. SELBY-BIGGE.

Electric power has been applied in this country hitherto chiefly for the purposes of traction, or for carrying out various operations in mining work, such as hauling, pumping, winding, ventilation, drilling, etc., and its chief advantages and characteristics in these branches are now very generally known. All these applications up to the present have come under the head of long-distance transmission, and there has been a general tendency on the part of engineers to consider applying electric power only in those cases where the power has had to be transmitted a considerable distance. The author is particularly anxious to draw the attention of engineers to what he may term short-distance transmission, or concentration of power. Seeing that it may be considered as coming within the scope of the iron and steel industries, ironstone mines, blast furnaces, iron and steel works, engineering shops, shipbuilding yards, the author will endeavour to point out the cases in which electric power is applicable to each of the above.

I. Long-Distance Transmission.

Ironstone Mines. — When transmitting electric power long distances it is necessary, in order to keep down the cost of the conducting cables, to employ high-tension currents—that is to say, the generating dynamos are wound to give off their power at a high voltage and small current. It has hitherto been the practice in mining work to convey the power at voltages of 300, 500, or 800 volts. Electric power in this way may be transmitted with a comparatively trifling loss to distances of several miles in length. It was not long therefore before electricity found an opening in its application to various mining operations, and especially to hauling and pumping. It was the author's privilege some two years ago to apply electricity in the Cleveland mines for drilling purposes, and since then these electric drills have proved themselves in every way a thorough success, and their use is being further extended into other mines in the district. The voltage in the case of the electric rock-drills does not exceed 300, as the power involved is comparatively small, and the distances do not exceed one to two miles in length. In the case of ironstone mines situated at any great distance from the main line, or in cases where a special line has to be built to the mines, an electric plant could be laid down, not only to operate the drilling in the mine, pumping the water, hauling out the ironstone, but could also be employed to generate current, at the same time for performing all the traction on the branch line. The whole of this work could be performed by current generated from a single engine and dynamo at the mine itself. In the case where several ironstone mines are situated in close proximity one to the other, a central power station could be laid down, by means of which there would be no separate steam plants situated at the different mines, these all being replaced by electric motors, driven off one main generating dynamo situated at the central station. There is no difficulty whatsoever in carrying out the winding, hauling, pumping, drilling, and ventilating arrangements at these mines electrically.

Blast Furnaces.—There may be some at this meeting who may think that the author now proposes to work blast furnaces by electricity. He regrets, however, it is not yet in his power to revolutionise the world by doing this. He would, however, seek the aid of blast furnaces in generating his electricity and considers that, after a waterfall, a Cleveland furnace is the next best friend to those desirous of generating electric power economically. In many cases there are large amounts of waste gases available from the furnaces. These are generally used for firing the boilers necessary for driving the blowing-engines, etc., but there is frequently a considerable amount of waste gas left over. It is with this waste gas he would propose firing the boilers in connection with the electric generating plant. The power thus generated could be transmitted at a high tension to engineering works situated at a considerable distance, and, if necessary, transformed again to a lower tension for use in the works. At blast furnaces themselves there are not a great number of applications to which electricity could be adapted for driving purposes, excepting, perhaps, in pumping water from a neighbouring river for condensing. The mineral hoists could be worked electrically.

II. Short-Distance Transmission and Concentration of Power.

Iron and Steel Works.—By short-distance transmission the author means the distribution of electrical energy for the purposes of driving engineering works. First of all, let the case of iron and steel works be taken, and the classes of machines most frequently employed in these works be considered. These will be found in a great measure to consist of the following: punching and shearing machines, straightening machines, cold and hot saws, drilling machines, planing machines, blowers, overhead travellers,

TABLE A.—Electric Motor Tests taken at the Works of Messrs. Dorman, Long, and Co., Middlesbrough.

Description of machine.	Driven by engine capable of indicating	Replaced by motor capable of indicating	Voltage at generator.	Voltage at motor.	Current taken by motor.	E.H.P. absorbed in doing work.
Group of machines as under—	H.P.	H.P.			Amperes.	Per cent.
Three cold saws Two ending machines One saw-sharpening machine	27	10½	120	115	70	10·7
Troughing straightening machine	14	3½	120	118	12	1·9
Double-ended punch, punching four holes one side and one other	14	5	120	115	25	3·7
Straightening machine, all sections	14	3½	120	115	15	2·3
Straightening machine, biggest sections	16	3½	120	115	35	5·4
Cold saw, 26in. diameter	9	3½	120	110	15-27	2·2 and 3·9

The saving in coal effected on above machine tools amounted to 30 tons per week, after the adoption of the electric system.

locomotive cranes, rolls, winches, scrap breakers, etc. In connection with iron and steel works there are frequently found girder shops, fitting shops, etc., in which the machinery is driven through shafting and belting off one or more engines situated in the shop. In laying down machinery of the above class it has almost invariably been the practice, not only when the machine tools are driven by separate engines, but also when they are driven by belting and shafting, to make allowances in these engines for very large losses, due to condensation or leakage in steam-pipes, or to friction caused in the belting and shafting. It is a well-known fact that the power actually expended in performing the work on these various machines is a mere fractional part of that transmitted from the generating source. Although attention has been paid to the economy of the main engines, the question of that in the small engines driving these machine tools, and the conveyance of steam, has often been entirely overlooked, and an enormous waste has been going on in this manner for years past. With the advent of the electric motor this condition of things was at once changed.

Table A gives results of experiments that have been recently carried out by the author, in conjunction with Mr. H. Panton, on the actual power absorbed by various machine tools in doing their work. The figures are extremely interesting, as showing the very small amount of power absorbed by the different tools when doing their work.

The author now wishes particularly to draw the attention of engineers to the concentration and distribution of power in works by means of electricity, and in order to fully demonstrate his ideas on this subject he has had two diagrams prepared, one showing the various cases of power transmission one meets with at an old works, and the other showing the way in which these works could be remodelled, and what savings could be effected by a judicious application of electric power. Of course the works represented above are purely imaginary, but it will be found that almost any other works will contain some or other of the examples of power transmission depicted on this plan. The plan contains examples of power transmission met with in iron and steel works, engineering shops, shipbuilding yards, etc. In the case of the old works there are examples: (1) of a large number of scattered steam-engines; (2) long lines of shafting and belting in the various shops; (3) considerable lengths of steam-pipes; (4) separate and scattered groups of boilers; (5) low-pressure steam; (6) old or uneconomical engines, especially in the smaller sizes; (7) intermittent character of the work. Turning back to these cases, it is very evident to all engineers the great economy which would be realised if all these scattered engines could be concentrated in one large and highly efficient engine. The amount of coal taken per unit of work done would necessarily be very much less, and in replacing these engines by electric motors the services of a large number of men could be dispensed with. Taking the second case of shafting and belting, the author thinks that few engineers really realise what is actually lost in the transmission of power through long lines of main shafting, countershafting, pulleys, belts, etc. The power lost has often been ascertained to vary between 30 and 69 per cent. of the total power transmitted.

The author will now proceed to demonstrate a manner in which these old works could be entirely remodelled so as to effect an enormous saving both in coal consumption, wages, and upkeep. The first thing to be done is to make a general survey of the whole works, and to have as many engines indicated as possible. Where this cannot be done, it would be advisable to lay down a small temporary installation of an engine and dynamo, with a motor which could be transferred from one machine to the other, in order to ascertain accurately the exact power absorbed by the machine in question. In this way an accurate opinion could be formed of the amount of power actually required for operating the different machines throughout the works. Having arrived at the total horse-power absorbed by all the scattered and outlying machinery, it is advisable to divide this into, say, two units of power. If the total power involved is 1,000 h.p., this would mean that it would be advisable to have two units of 500 h.p. each. The reason why so large a power is selected as unit is that in electric power installations the load diagram will be found to be of quite a different nature to that of an electric lighting station, which exhibits a more or less constant rise and fall according to the time of day, whilst the load-line in an electric power station is of a very different and fluctuating nature, varying at times between a quarter and full load, half load and full load, and so on. It is necessary, therefore, both for simplicity in working and for economical reasons, to have a steam dynamo capable of giving out current for at least half the installation. It would be necessary in the case of the five small machines to keep them all running, even if the load was only 25 per cent. of the total, in case at any moment the load should suddenly rise. This practice has been adopted in nearly all large power installations on the Continent, and the author cannot help feeling that it is the right one. In the case of works where waste furnace gases are available, the evident site for the generating plant would be in close proximity to these furnaces, in order that the boilers of the generating plant might be fired by the waste gases, the cost of the production of the electric current being thereby reduced to a minimum. Should there be no waste furnace gas available, the generating plant should then be placed close to the main battery of boilers in the works, and if these boilers are of a pressure below 80lb., it will be found economical to lay down entirely new boilers of, say, 150lb. to 180lb. pressure. Having settled on our site, the next question to be decided is the form which the generating plant should take. In the case of a unit as large as 500 h.p., one out of three alternatives may be resorted to; a compound condensing Corliss engine running at 80 revolutions per minute, with a multipolar dynamo, built up after the continental fashion with the armature forming the flywheel of the engine, may be employed. Great confidence may be placed in a plant of this description, but the initial cost is comparatively a large one, owing to the large dimensions of the dynamo and the slow speed at which it runs. If this speed were doubled, and an engine running at, say, 160 revolutions a minute taken, it would be possible to employ a triple expansion marine engine provided with condensing arrangements. A great reduction will be effected in the cost of the dynamo, and an engine of this type should work with great economy. It will be found necessary, however, to provide this marine engine with proper automatic expansion and regulating gear, owing to the variations in load and the necessity of absolute steadiness in running. The third alternative is still further to increase the speed of the dynamo, and to employ an engine of the high-speed type, similar to those adopted in our electric lighting stations. These engines would run at about 300 revolutions per minute, thereby doubling the previous speed of the dynamo, and again reducing its cost. These high-speed engines would be of the triple-expansion type, and provided with condensing arrangements. Their consumption should not exceed 15lb. of steam per indicated horse-power per hour. In any case, the plant to be laid down should be of the steam dynamo type—that is to say, steam-engine and dynamo combined on one and the same bedplate, and direct coupled.

Having taken a decision as regards the generating plant, it is necessary next to consider the actual application of the electric motors themselves to the various machines, and the distribution of the power generally. As works which have not a greater extension than 300 or 400 yards in length are now under consideration, the voltage which will be employed will be of a low tension. In this manner can not only the whole of the power be run off the one single generating plant, but the entire lighting, both arc and incandescent, of the works themselves. The author considers that the voltage in such a case should be 120 volts. If the distances are too great to allow of this, owing to the expenditure in copper, the voltage could be increased to 500 volts. In iron and steel works, however, the low voltage is for many reasons preferable, as it is far easier to maintain a high insulation on a low voltage system than it is when a high voltage is employed. In all cases where new machinery is ordered for extensions or otherwise in the works, it would be preferable to embody the electric motor in the actual construction of the machine tool itself. In the case of old works this is hardly feasible, and the next best thing to do is to drive direct by belt on to the flywheel of the machine in question.

Supposing that the whole of the outlying machinery is actuated by electric motors, and that motors have been substituted for the engines and boilers on the overhead and locomotive cranes, that the driving power in the fitting shops and other places where shafting is employed has been split up, and that separate motors have been applied to the various countershafts, the following are the practical results which will have been obtained by remodelling the old works on the lines described.

Coal Consumption.—The total efficiency of the new installation, provided that the distances involved do not exceed 500 yards,

Digitized by Google

should attain 75 per cent. The loss of 25 per cent. would be made up as follows;

	Per cent.
Loss in main generating dynamo	7
Loss in the mains	3
Loss in the motors	15

In many works where the engines are very much scattered, it will be found that the coal consumption per horse-power of work turned out will amount from 8lb. to 15lb. of coal and even more. Although a great reduction in the coal consumption will be effected through the use of the improved class of machinery employed and means for transmitting the power generated, there is another way in which the coal consumption can be further decreased, and that is by the instantaneous switching off of the motors when not in use. It is advisable that in every case the electric lighting of the works should be combined with the power, current for the lighting being obtained from the same generating dynamo.

Wages.—The next point to be considered is that of wages. It is evident that by the entire suppression of the scattered boilers, the services of a considerable number of stokers can be entirely dispensed with. This is also the case with those steam-engines which require an engineer to run them.

Upkeep.—We have now a further point to consider, and that is the question of upkeep of such an electrical installation. The upkeep on electric power installations which have already been running over three years, involving the use of a large number of motors, arc lamps, etc., has proved that this can be safely estimated at something under 5 per cent. on the total capital expenditure of the electric installation. No hard and fast rule, however, can be laid down for the exact cost of upkeep, as this must necessarily vary with the different classes of works to which electricity is applied.

Control.—The author thinks that one of the most important features in connection with electric power installations is the absolute check or control one has over the coal consumption and running expenses at the works. By means of an automatic registering ammeter placed in the main dynamo circuit, the total amount of power going off into the works will be recorded on a card, and the coal consumption for the day having been kept, the cost of production per unit of electrical energy can be ascertained. Owing to the self-indicating nature of electric motors, in this and other ways can a most perfect check be kept on the running expenses of the electric power plant, and the slightest loss due to leakage or undue resistance in any part of the electrical apparatus can be at once detected and remedied.

Rolling Mills.—It is quite within the bounds of possibility that electricity may find a new opening in its application to driving the lighter class of rolling mills. The result, as far as economy in steam consumption is concerned, would show a great saving on methods formerly employed. The saving would be arrived at in the following manner: Instead of the present form of engine used for actuating the rollers, which is necessarily of a somewhat uneconomical nature owing to the work it has to perform, and in which the cut-off is of a very imperfect character, an engine could be laid down on the most highly economical principles, working at a high pressure, with three expansions of steam, and taking not more than 1½lb. of coal per 1 h.p. per hour. This engine would be coupled direct to a dynamo of suitable power, and the steam dynamo generator would be kept running continuously. On each set of rollers would be directly coupled an electric motor. The switching apparatus would be worked by means of hand and foot levers, almost in identically the same manner in which the steam is shut on and off existing rolling-mill engines.

The main advantages, however, to be derived from the electric system would be the following: (1) The question of dead centres would be practically eliminated—an electric motor in itself, unlike a steam-engine, having no dead centre. The main engine driving the generating dynamo being kept continuously running, the difficulty of dead centres would be overcome there also, the result being that the total size of the engines employed would be considerably reduced, as in the present case it is necessary that either cylinder of a rolling-mill engine should be capable of starting the rolls from nothing to full load, in case one of the engines should be on its centre. (2) Owing to this new arrangement of driving, a totally different class of engine could be employed to what is now used, and instead of using 7lb. to 8lb. of coal per indicated horse-power owing to its imperfect cut off, the coal consumption should be reduced to 1½lb. per indicated horse-power. (3) A considerable number of small mills could be actuated in totally different parts of the works by means of one generating engine and dynamo, and would thus save wages and upkeep over several smaller engines scattered about. (4) The whole of the auxiliary engines required for working the live rollers, elevating, or transverse gear, overhead cranes, etc., could be replaced by electric motors all worked off the one generator. (5) Great economy in steam consumption owing to concentrating the production of the power in one spot, under highly efficient conditions.

Engineering Works and Shipbuilding Yards.—The same arguments apply to the application of electricity to engineering shops and shipbuilding yards as have already been cited. The following table, calculated by Mr. Félix Mélotte, shows a very interesting comparison between the efficiencies, obtained on a varying load, of electrical and mechanical transmission of power.

From this table it will be seen that the two systems of transmission, which at first appear to be equivalent, become very different as the load diminishes. Thus, when only one-fifth of the power is developed, electrical transmission still yields 47·2 per cent., whilst mechanical transmission has had all its power absorbed in the constant frictional loss of 206 h.p.

Electrical Transmission:						
Load on the engine	1,000	750	500	333	250	200
Constant frictional loss	50	50	50	50	50	50

Useful effect	794	544	294	127	44	0
Final efficiency, per cent.	79·4	72·5	58·8	38·1	17·6	0

Results Obtained.—There are few works in this country, if any, that are solely actuated by electricity. The principal applications of electric power for driving works, up to the present, may be found in the workshops of electric manufacturers themselves, who have naturally had more opportunities for investigating the advantages to be derived from electric driving. In order to give some idea of results actually obtained in the running of works for a considerable period, the author will take some figures from electric power installations carried out in Belgium, which have now been running some three years, cases in which the entire works have been actuated solely by electric power. One of the first, and perhaps most important, electric power installations that has been laid down in that country is that of the National Arm Factory, at Herstal, near Liège.

Following the example of the National Arm Factory, the Belgian Government decided to remove all the steam-engines and boilers from the Royal Arm Factory at Liège, and to replace them by electric distribution. It was ascertained that for a certain portion of the work which, previous to the introduction of electric driving, had taken three tons of coal per day, this was found to have immediately come down to 900 kilogrammes, or less than one ton, for the same amount of work done.

About a year and a half ago a 100-h.p. dynamo and six or seven motors were laid down at the glassworks of the Val St. Lambert, Belgium, the total efficiency attained coming out to 75·5 per cent. At the zincworks of the Vieille Montagne Company a large electric power installation has lately been laid down, by means of which these old works will be entirely remodelled, every engine and boiler on the place being done away with. The efficiency of the engine is 90 per cent., that of the main generating dynamo 90 per cent. at full load, and the efficiency of the distributing cables, also at full load, is 98 per cent.; the average efficiency of the motors is 86 per cent., and the commercial efficiency of the whole installation is therefore 68·5 per cent.—that is to say, the proportion of the work done to the indicated horse-power of the steam-engine. A continuous-current transformer is used to reduce the voltage from 500 to 100 volts for lighting purposes. Several works in Germany and Switzerland are also operated solely and entirely by the electric system.

Conclusion.

Taking into consideration all that has been stated in the preceding, it will be seen that electric power is destined in the near future to become an important factor in the iron, steel, and engineering trades. Whether applied for the purpose of long-distance transmission at the mines, or for short-distance transmission and concentration of power at works, great economy will be realised in wages, fuel, and upkeep over methods hitherto employed. Old works can be remodelled with advantage, as shown in the cases of the Royal Arm Factory and the Vieille Montagne Zincworks in Belgium, and the case of Messrs. Dorman, Long, and Co.'s steelworks at Middlesbrough, and what possibilities lie open to those contemplating laying down entirely new works! The Bedson Wire Company finally decided on adopting electricity as their sole power for manufacturing purposes. These works in may respects are so entirely novel, the question o economy has been so minutely gone into, that the author believes that Mr. Bedson, in the course of a few months, will be able to publish a record in working efficiency and steam consumption which has seldom, if ever, been equalled. Messrs. Bell Bros., of Middlesbrough, who have also been taking great interest in the electric power question for some time past, are installing electric power at their Clarence Works.

INSTITUTION OF ELECTRICAL ENGINEERS, May 10.

Sir David Salomons in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Associates.—Frederick Herbert Berry, 14A, Clerkenwell-green, E.C.; Arthur Carpenter, 15, Clonlee, Larne, co. Antrim; Harold William Couzens, Corporation Electricity Works, Taunton; Svend Aage Faber, 1, Fern Villas, Albert-road, Teddington; A. G. Jeffreys, Woodridings, Pinner, Middlesex; Chas. Wm. Godson Little, 38, Parliament-street, Westminster; Thomas Blackwood

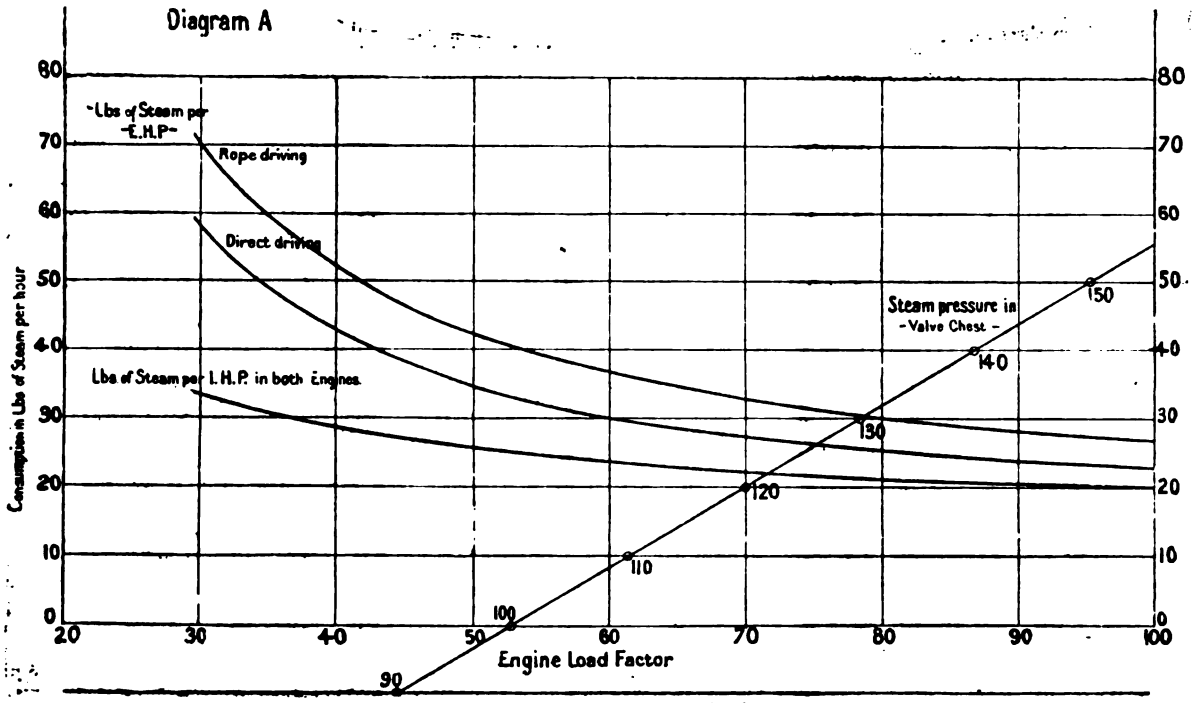
Digitized by Google

Murray, B.Sc., Heavyside, Biggar, N.B.; Richard Wesley Olver, care of Rev. G. W. Olver, B.A., 10, Clifton-road, Brockley, S.E; William Turvey, 4, Aubrey-walk, Campden-hill, W.

Students.—Ernest Cardin, North Hills, Thurlow Park-road, West Dulwich; Reginald Charles Carty, 40, Woburn-place, Russell-square, London, W.C.; Walter Harding De Winton, Gerald Graham, and Arthur Patrick O'Brien, Faraday House, Charing Cross-road, W.C.; Robert John Strike, 116, Flinders-street, Moore Park, Sydney, N.S.W.

THE COST OF ELECTRICAL ENERGY.

The accompanying diagrams are three of those referred to in the paper read before the Institution of Electrical Engineers by Mr. R. E. B. Crompton on "The Cost of Electrical Energy," and which was published in our issue of the 27th April.



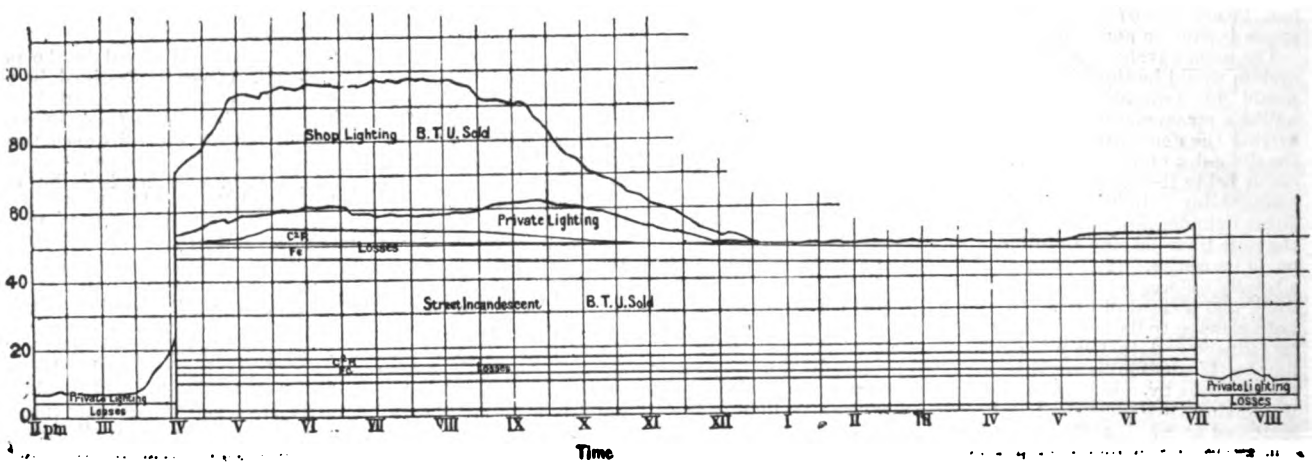
Calculating the Load Factor at Stations.

Discussion.

Mr. Raworth, who opened the discussion at the previous meeting, said that the paper was most comprehensive, and that it seemed to include nearly the whole education of the electrical engineer. The author had thrown up Lancashire boilers and pinned his faith to those of the Babcock type. It was a good effort to endeavour to reduce the cost to 3d. per unit to consumers. At Bradford and Newcastle they already delivered eight units per £1 of capital expenditure, the St. James's Company five units, the Westminster four, the Liverpool four, and Oxford two units. The system at Oxford, although perfect, appeared to cost too much to pay a dividend to the shareholders. With regard to the power question, it was only of late years that they had had the advantage of accurate tests carried out by Prof. Kennedy and others. The speaker had never bought any boiler other than the Babcock, except under compulsion, and he had put down more than half of the Babcock boilers sold in this country. They had given him perfect satisfaction, and he agreed with the author that they did not give wet steam. He was also in accord with the author that the increased efficiency of the engine should come out in units. Concerning the question of alternators, they had found out that if they could get rid of the ropes they would do better, 6 per cent. being lost by the use of ropes. As soon as they were able, they abandoned the rope driving and adopted direct operation. He hoped next time the author would give them better figures for the alternating plants than he had now done. With regard to engine losses, the Willans engine was particularly efficient from the point of view of the makers; an efficiency of 89½ to 90 per cent. was good. But it was owing to the fact that the makers of ordinary double-acting engines had never been in the habit of testing these engines that the efficiency was not a top efficiency. He could get, and anyone could get, ordinary vertical double-acting engines giving 92 per cent. There was no difficulty about it. Double-acting engines could be made to go up to 95 per cent. The author had, he thought, fallen into a serious error in regard to the efficiency of distribution in alternating-current systems, but he would leave that matter to experts.

Mr. Crompton made some additional remarks before the resumption of the discussion. With regard to the boiler-test diagram, it was interesting from many points of view. It showed that the evaporation of pounds of water per pound of coal had risen to 9 from 5·2. This class of test was one which should be made frequently at central electricity stations as leading to economies.

Major-General Webber stated that, having read the paper carefully, he found that it was open to a good deal of criticism. Why was 5,000,000 units selected by Mr. Crompton as his ideal? Mr. Crompton must have been dealing with a load for lighting purposes. In Kensington, which Mr. Crompton knew best, most of the demand was for incandescent lamps. He wanted to know on which system the author had based his possible estimate. Of three London companies respecting which figures were available, the capital expenditure per lamp was £3. Did Mr. Crompton expect to bring it down to £1 6s? Only 40 miles in London of the districts lighted were laid with mains on each side of the street. Was the author's ideal based on the future of a district like Kensington. Coming to the question of Mr. Crompton's method of collecting his information, in the letters which had been sent out by Mr. Crompton to the engineers of stations, the questions had been put in such a way as to lead to



Analysis of Load Curve at Chelmsford Station for December 9, 1893.

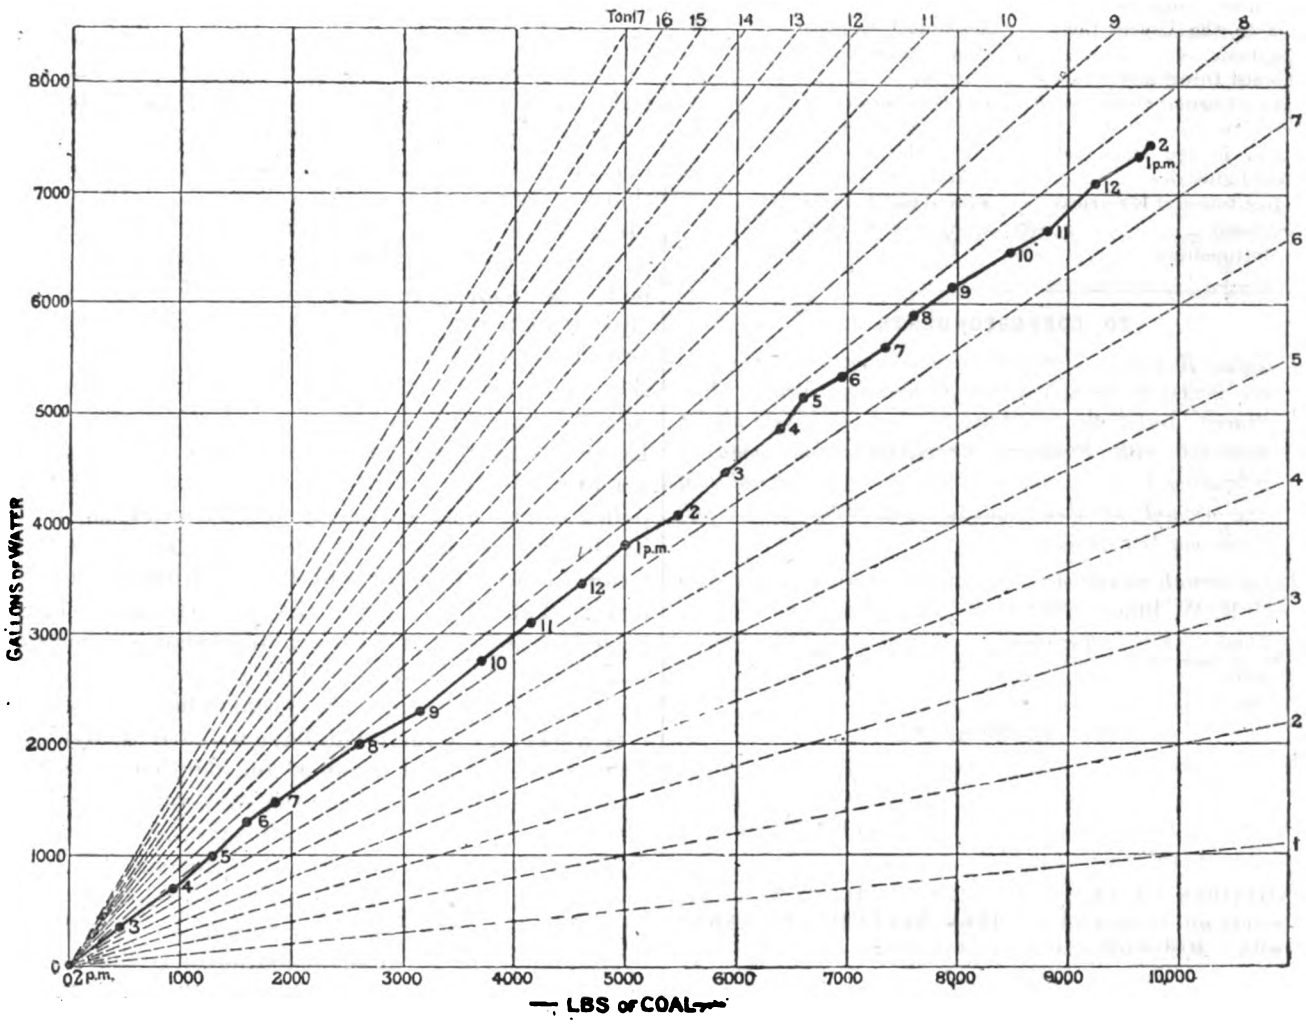
Digitized by Google

certain results being obtained. He had also stated that if the full information was not given he was prepared to fill up any information omitted, from data in his possession. In one case the speaker knew the engineer had declined to give information at all. The engineers would have been glad to do so had they been allowed to compile the tables. Chelsea was a mixed station, with accumulators, transformer-motors, etc., but had been omitted from the mixed system in Mr. Crompton's table. If Mr. Crompton, in drawing up his figures, had confined himself to those companies with which he was connected, the results would have been far more reliable than the tables which had been compiled, No. 6 being the crux of the whole matter. When Mr. Crompton gave 3d. as the price, with 1·68d. as profit, it left doubts as to whether Mr. Crompton was convinced of the soundness of his results.

Mr. Mark Robinson said that if Mr. Crompton was ahead, yet some of his prophecies had come true, and the speaker hoped that that would be the case with respect to the theory of a consumption of 2·5lb. of coal per unit. It rested on the evaporation of the boilers, the consumption of the engine, and small friction. In reference to the dryness of steam from water-tube boilers, he had at Thames Ditton found wonderful results from a Nicholas boiler—a French water-tube boiler. There was only ¼ per cent. of moisture in the steam. The boiler had also been worked at double its rated capacity, and then the moisture was 1 per cent. Much the same results had been obtained from a Babcock boiler. As other views had been held at Thames Ditton, he considered it but fair to mention this. As regarded the consumption of only 12lb. of steam by the engine, this had been done by the Sulzer engine. A large mill engine had taken 13½lb. A large high-speed engine could work on 13. By jacketting, etc., a high-speed engine could be brought down to the consumption of the Sulzer, but there would be disadvantages in connection therewith, as the lowest steam consumption could not be obtained in the same engine as the lowest friction. Mr. Raworth had gone a little for the Willans engine by saying that it had a good brake efficiency, but so had all vertical engines. Now, large compound or triple-expansion engines were not readily handled on brake trials, and it did not seem safe to judge of the efficiency running loaded by what the efficiency might be running light. With single-acting engines the losses due to friction were almost constant. Messrs. Mather and Platt were making for the speaker a brake for 1,200 h.p., and they hoped to run a large engine on it which would settle various points. The result of a number of tests made at Thames Ditton showed an average of 90·6 brake efficiency with new and stiff engines. The speaker considered that Mr. Crompton had made an excellent suggestion when he advised the use of a pressure gauge on the steam chest. It was of much value, though not with automatic expansion gear.

Mr. Geipel said it was encouraging to find that 3d. was the price within measurable distance, but Mr. Crompton had been too modest. He did not see why Mr. Crompton had reduced the prices for wages, maintenance, etc., and not the first cost of the installation. He thought that engineers could do something in the latter direction. Often unnecessarily expensive chimneys were built and condensers were erected for a full load, and were only in full use at distant intervals. He considered that the first cost might often be reduced to half that of Mr. Crompton's estimate if high-tension generators and low-tension distribution were employed. Coal would be far dearer, stores would be double, and wages and maintenance also double Mr. Crompton's. Economy could be effected by setting boilers so as to minimise loss by radiation, and the speaker described how he had set a Babcock and a Lancashire boiler with that object.

Mr. Schonheyder said that in making the boiler experiments the pounds of water evaporated per square foot of heating surface should have been stated. The author had referred to his (the speaker's) meter, which had generally worked satisfactorily. That meter had lately been improved, and now, as far as his experience went, it would get over the difficulties incurred in measuring hot water.



Clinometric Chart of Boiler Trial.

Mr. Hammond, in the course of a rambling speech, said he would have liked half an hour to discuss the matter. He stated that the paper was a very valuable one The figure of 3d. per unit, with an output of 5,000,000 units meant £62,500 per annum. Perhaps Mr. Crompton would inform them how many towns in England had gas companies with such an income, at, say, 1s. 6d. or 1s. 9d. per thousand, corresponding to 3d. per unit. The author had omitted the question of depreciation, and that was an important matter, notwithstanding the keeping of plant in a good condition.

Mr. McLaren contended that in the published tests of engines the information was often incomplete and misleading. If an engineer was laying down an installation and accepted the figures of tests put before him he might be very far astray. The true secret was to test the engines in connection with the boilers they had to work with, and, having carefully noted the data, to see what the actual consumption was. The evaporation of a locomotive type of boiler was very much nearer 10lb. than 7lb. as stated by the author. The great economy at Oxford was due to the triple-expansion slow running engines.

Mr. McLane made several corrections concerning the author's statements in regard to the Oxford station.

Mr. Burnett having made a few remarks on the boiler question, the discussion was adjourned until the 24th inst.

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THE METROPOLITAN.

It is not often we have any sympathy with the contents of the *Journal of Gas Lighting*, etc., or its electric lighting memoranda, but with its last issue we have something in common. We must give our contemporary credit for ability to find out and state plainly everything that is said or can be said against electricity. A red rag to a bull is a mild irritant compared with the word "electricity" to this gas journal. Its cursing, however, has had little or no appreciable effect upon the progress of the industry, and, with commendable consistency, it has never tried blessing. This week it devotes a considerable space to the consideration of what Sir John Pender said to the Metropolitan shareholders at their meeting. Now, if there is one man living whose speeches are not worth listening to, or who can in speaking cram more platitudes into a given space of time, that man is Sir John Pender. Of all the companies he is connected with—and their name is legion—we doubt if there is one that shows a worse history than the Metropolitan. Its conception was unsatisfactory, inasmuch as very large sums went to somebody or somebodies as promoters. Then we always look upon founders' shares with suspicion, and that distrust we find is general among the real investors, many of whom refuse to invest in a company where founders' shares exist. Further, as we said when giving the balance-sheet, we do not believe in it. We do not believe in that policy of charging certain items to capital, as shown by this balance-sheet. It allows of too easy manipulation in order to show a profit and distribute a dividend. The misfortune is that the shareholders at their meetings sanction the whole balance-sheet and whitewash the directors. The men we sympathise with in such companies are not shareholders, but the real workers, the men who have to earn a dividend upon a large capital when a considerable portion of that capital has not been spent productively. A steam-engine of so many horse-power can under ordinary circumstances only earn—when used for electric light purposes—a certain amount in the year, and this is the one point to which we should like again and again to direct attention. If the capital is spent in some other direction than plant, the return for it is limited to the amount capable of being earned by the plant. It is not very difficult to obtain a fairly accurate forecast of return. Taking the Metropolitan still as an example, we are told that the average price per lamp is 8s. 9d., and that the number of lamps connected is one hundred and seventy-five thousand. The gross return upon that average number of lamps for the year could only be £76,562. The net return according to this year's balance-sheet is as sixteen to sixty-nine; so with a revenue income of £76,562 the net return would be under £18,000. From these considerations it is seen that unless considerable economies can be effected in the management and generation costs, it will require at least another one hundred thousand lamps to be supplied without further increase of capital in order to get a 5 per cent. dividend. But Sir J. Pender says that more capital is wanted. Is it

Digitized by Google

not almost time that shareholders began to ask Sir J. Pender what he knows about the whole matter, and to get an independent examination as to the exact capabilities of the company's work? We have merely taken the balance-sheet and the chairman's speech as our guide, and they show us how utterly mismanaged the whole concern is. Our contention is—and we think we can prove it up to the hilt—that when the supply of electrical energy has failed it has been owing to gross mismanagement, and not to any other cause. Hence we are doubly anxious that these selected points of attack by the gas journals should not be generally accepted as points which those interested in the electrical industry would support.

THE LONDON ELECTRIC.

It is more convenient to keep our remarks concerning the London Electric Company distinct from those on the Metropolitan. The company that hath no history is in a happy position, but that is not the case with either the London or the Metropolitan. According to the reasoning pursued with the Metropolitan, the London, with only sixty thousand lamps, and a capital of close on a million pounds, is, so far as its shareholders are concerned, in a perilous state. But long ago the shareholders of the London gave up hopes of getting a good return for their money. Up to the present balance-sheet the figures have been adverse. Now they about balance. We had hoped to have seen a little further progress. It is long since we pointed out that according to the then price of the shares, if the company ever paid a very moderate dividend the investment of those who came in at the low prices would be good. The quotation has now hardened up to one for the five pound share, so that 1 per cent. on the nominal capital requiring a distribution of ten thousand pounds for dividends would give 5 per cent. on the purchase. Supposing the rate of increase to be during the current year the same as it has been during the past and no increase of capital, the amount available for dividend would be about four thousand pounds. But, unfortunately, it seems that there must be a further increase of capital, so that the future prospect of dividend depends somewhat upon that increase. A comparison of the last two balance-sheets will show that with a decreased charge per unit the total amount received has increased, while considerable saving has been made in various directions. Perhaps, however, the most important paragraph in the whole report is that of the engineer when speaking of the new transformers. We are, fortunately, able to extend that paragraph. The total horse-power of transformers used is 3,487, of which, as will be seen in the report, 1,477 is new since the last month of the year. The insertion of these new transformers raised the efficiency of distribution no less than 18 per cent., and it is estimated that when all the old transformers are replaced by the new type, the efficiency of distribution, which at the end of the December quarter was only 45·43 per cent., will be raised to about 70 per cent. Electrical engineers will, we feel assured, be glad to have these figures, and we must congratulate the engineer, directors, and management of this company for having stuck to their work and brought matters to such a point that an income may confidently be expected.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

WRIGHT'S DEMAND METER.

SIR,—I notice some remarks were made at the meeting of the Northern Institute of Electrical Engineers raising the question of the drop in Mr. Wright's demand meter in use at Brighton. It will probably interest your readers to know that the total energy absorbed in the small instruments at their fullest possible load is only three watts, and in the large ones only seven watts. It is obvious that as the maximum drop is, of course, equal to these figures divided by the maximum current, it is so small as to be negligible in ordinary installations.

Thus, in practical working, the drop in a 25-ampere instrument when carrying its average load of two-thirds of its possible capacity will be ·28 of a volt, which I think warrants my saying it may be disregarded.—Yours, etc.,

(For the Reason Manufacturing Company, Limited)
HERBERT C. HUGHES, Secretary.

Brighton, May 8, 1894.

THE PRELIMINARY EXAMINATION IN "ELECTRIC LIGHTING AND POWER DISTRIBUTION."

SIR,—Following is a copy of a letter addressed by me to Sir Philip Magnus, relating to the way in which candidates in the above examination are to have the results made known to them. This and the reply thereto will, I venture to think, be of interest to both teachers and students.

There is little doubt that the number of candidates will rapidly increase year by year, and it is to be hoped that at some future time the institute authorities may see fit to modify their decision.—Yours, etc.,

W. PERREN MAYCOCK, M.I.E.E.

Croydon, May 9, 1894.

[COPY.]

"26, Stafford-road, Croydon,
"May 5, 1894.

"Sir Philip Magnus, Secretary, Examinations Committee,
"City and Guilds of London Institute, Exhibition-road,
"South Kensington, S.W.

"Dear Sir,—With reference to the newly-instituted preliminary examination on 'electric lighting and power distribution,' may I ask in what manner the results will be made known to the students?

"It has been a matter for surprise to others besides myself that your committee should have decided not to give certificates for this examination, but if each successful candidate is to receive a note from the institute recording his success, that would in a measure make up for the absence of a formal certificate. From several years' workshop experience I know there are very few electrical artisans proper who can hope to pass beyond the preliminary grade of this subject: to this numerous class of workers, some duly authenticated acknowledgment of their having passed the examination in question would often prove of considerable value. If you will clear up this point, you will confer a great obligation on other teachers than myself and on the students, to whom they have to make known this correspondence through the medium of the electrical Press.—I am, Sir, your obedient servant,

(Signed) "W. PERREN MAYCOCK."

"City and Guilds of London Institute, Examinations
"Department, Exhibition-road, S.W., May 7, 1894.

"Dear Sir,—I need scarcely point out that the question

Digitized by Google

of granting certificates on the result of the preliminary examination in electric lighting has been carefully considered by the several committees of this institute, and that the rule in the programme is the result of much deliberation. A list of candidates who may have passed that examination will be forwarded, as stated, to each centre at which they were examined, and it will be left to the local secretary to inform each separate candidate of his success or failure.—I am, dear Sir, yours very truly,

(Signed) "PHILIP MAGNUS.

"W. P. Maycock, Esq.,
" 26, Stafford-road, Croydon."

STORAGE BATTERY TRACTION IN PARIS.

An interesting feature of the French Physical Society is the fact that on the occasion of its annual exhibition a visit is paid to some works in the neighbourhood of Paris. The annual exhibition for 1894 took place two or three weeks ago, and an opportunity was afforded the members of inspecting the accumulator station at Saint-Denis, where the batteries used for traction purposes on the two lines—Paris-Saint-Denis—by the Compagnie des Tramways Nord are charged. M. Dieudonné, who describes in *L'Electricien* of May 5 the plant at the charging station, remarks that the installation is on a larger scale than any of its predecessors.

It appears that M. Broca, director of the Compagnie des Tramways Nord, was the promoter of the undertaking to which we have referred on previous occasions. The Société du Travail Electrique supplied the batteries, maintains them, and guarantees their efficiency; and Messrs. Averly, of Lyons, the cars and motors; whilst Messrs. Garnier erected the steam plant. Each firm is responsible for the material furnished. The conditions imposed upon the contractors were to substitute accumulator cars capable of accommodating 52 passengers, of travelling at 7·5 miles an hour, with a possible speed of 10 miles in the outskirts of the city, 3¾ miles an hour on gradients of 40mm. per metre; the haulage, if necessary, of a separate car by the motor car, and a daily service of 84 miles per car.

The generating station contains two boilers, supplying steam to three engines, each of 125 h.p., and provided with horizontal cylinders and Corliss valve gear. One of these engines drives by belting a 60-kilowatt Desroziers dynamo running at 160 revolutions a minute. The other two engines, actuated at 70 revolutions, operate by means of countershafting two dynamos of the same type. The generators give 230 amperes at 260 volts, and are connected in parallel to omnibus bars on the distributing board. Each battery is connected to this board through a special circuit, comprising an ammeter, an indicator of the direction of the current, a cut-out, and a switch. The benches upon which the cells rest are

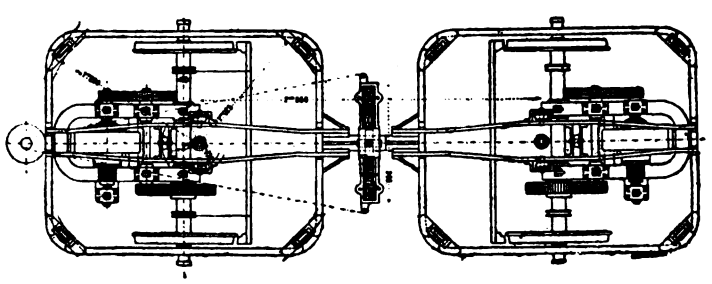

FIG. 1.

formed of tarred joists supported by brickwork, the cells being carried on glass insulators. These tables are provided with contacts, between which the batteries are arranged so that they are all coupled in series. The batteries are conveyed to and from the tables by means of small wagons, and they automatically make contact when placed in the cars.

The car body, as will be seen from Fig. 1, is carried on two trucks, and the motors each drive one axle by double-reduction gear, the ratio being 12 to 1. The motor is fixed on the one hand to the axle, and on the other to the frame. The motors are bipolar of the Manchester ring armature type, and are excited in series; the brushes are of carbon. According to the speed, the motors are operated at a pressure capable of reaching 200 volts; at 1,200 revolutions they give 19 h.p.

The battery, which is arranged under the seats of the car, comprises 108 cells carried in 12 ebonite boxes. They are connected in series, and each terminal is led to a small copper bar arranged on the sides of the box. Brass plates arranged on springs in the car are connected to the motor circuits by means of a coupling switch. Fig. 2 shows diagrammatically the connection of the switch. The brushes when fixed on the motor commutators are immovable; the reversal of the rotary movement is effected

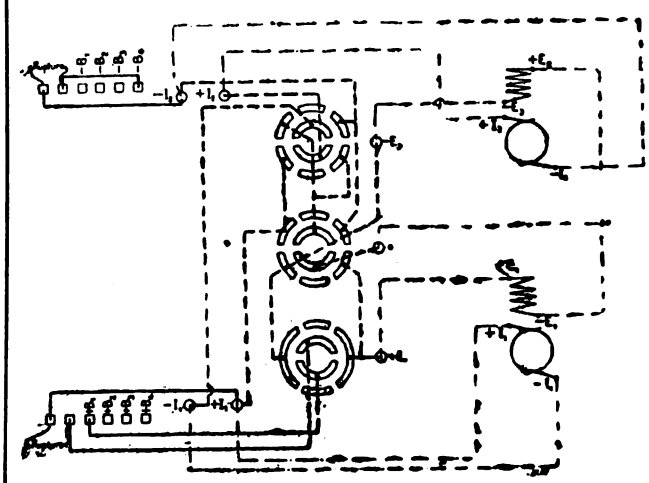

FIG. 2.

by reversing the direction of the current in the magnets. Each car then contains 12 boxes arranged in four groups, each having 27 cells in series, and which corresponds to a difference of potential of about 50 volts on closed circuit.

From the point of view of the energy to be consumed, each car has six parts: two motors, connected in series or in parallel, according as may be required, and four groups of batteries, which can be coupled in different ways to meet the requirements of the service. The motors are connected in parallel for high speed and in series for low speed.

The switch allows of being obtained the combinations indicated by the diagram given in Fig. 3: first, the four

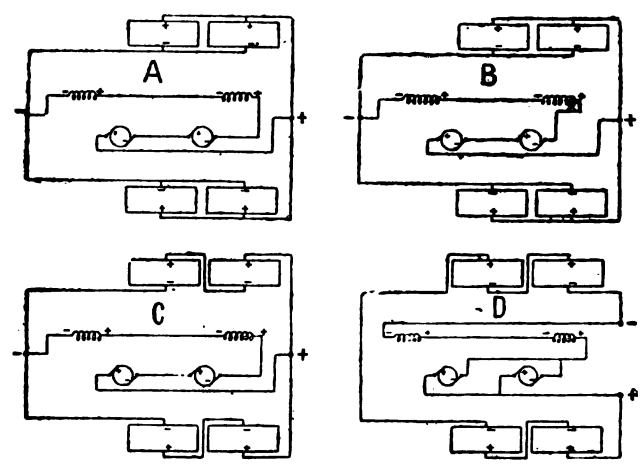

FIG. 3.

groups of batteries arranged in quantity, the E.M.F. 50 volts for starting, and a speed of 2½ miles an hour. The rings and the inductors are in series. With the same grouping of the accumulators, the inductors placed in series and the rings in quantity, the speed can be raised to 3·72 miles an hour. Second, two groups of sub-batteries in quantity and connected in series give an E.M.F. of 100 volts. Third, the four sub-batteries in series yield 200 volts. The speed of the car varies by changing from one method of connection to another in the relation of 1 to 2.

Digitized by Google

By the aid of the Fig. 3 and the cross-section and elevation given in Figs. 4 and 5, it will be easy to understand the various operations of the switch. On the upper partition of the box containing the cells is arranged a hand-wheel, provided with three handles. The working of the hand-wheel brings about the different ways of connecting the batteries already mentioned. The terminals are brought to contacts formed of spring plates; the movable drum around its vertical axis effects the determined combinations.

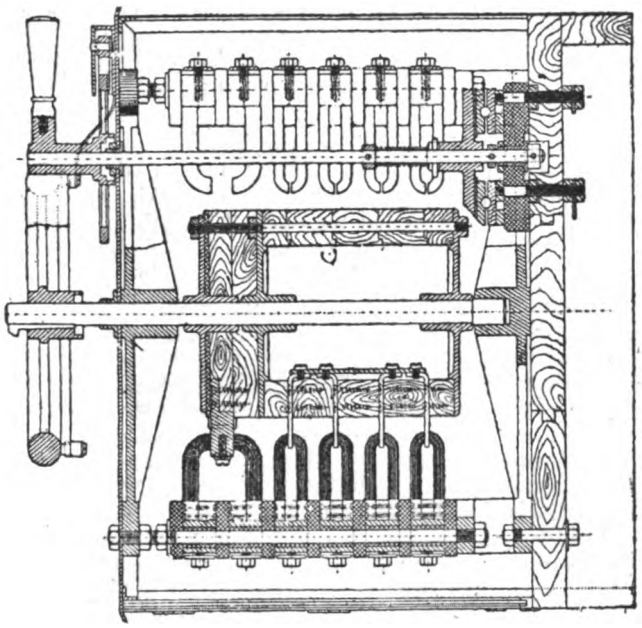

Fig. 4.

It is provided on its periphery with pallets, the insertion of which between the spring plates brings about contact. The upper disc gives communication to the motors. It is called the "rupture" wheel; its pallets are narrower than the others, but are much thicker, and are provided on the edges with two carbon plates, on which the breaking spark takes place. The wear is thus localised on these pieces, which are inexpensive and readily replaced.

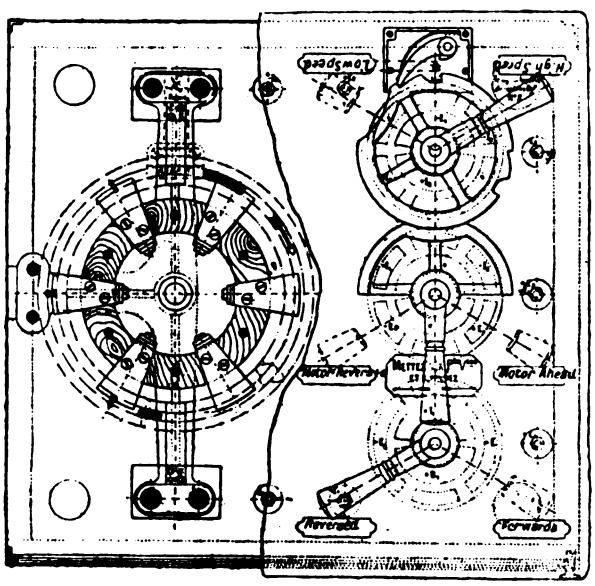

Fig. 5.

The second part of the apparatus, comprising the whole of the handles, serves to effect the coupling of the motors, the changing of the speed, and direction of rotation. The first handle, bearing the words "low speed," "high speed," allows of the connection of the motors in series or in parallel. It is connected to a wheel provided with two notches where a ratchet engages, and which prevents rotation from left to right. The rotation is freely possible in the reverse direction—that is to say, one can pass from high to low speed. To attain the high speed, it is only necessary to raise the ratchet. The second handle is used to cut out one of the two motors in case of accident. Before doing so the motor is short-circuited, and this can only take place if the motors are in series. It is at such a time necessary to be running at low speed so as to cut out a motor. The third handle is for the purpose of controlling the forward or backward movement of the car by reversing the current in the magnets.

The two tram lines worked by the storage battery cars have some steep gradients, and each car with a full complement of passengers weighs 12 tons. It is stated that the cost of working per kilometre run is ·53f. as against ·56f. for horse power—or, say, 8⅜d. per car mile for the electric cars.

THE COST OF ELECTRIC LIGHTING.

The managing director of the Crystal Palace District Electric Supply Company, Limited (Mr. George Offor), is to be congratulated for his energetic action in the direction of popularising the use of the electric light, especially in regard to its cheapness. We extract the following from a circular just issued by that gentleman:

"With the varying circumstances under which almost every individual uses the electricity, any opinions based upon the quarterly accounts of the company's customers must necessarily be more or less defective, unless the previous candle-power and cost of gas in each case could be compared with them. But one fact is very apparent—viz., that with experience in using the current the cost becomes less. And this is not only proved by the results obtained by thorough study and the exercise of great care in the management of the light, but the fact is also established by the returns of the supply companies, which show a reduction year by year in the annual consumption of electricity, and consequent cost, per 8-c.p. lamp installed. For example:

Electric supply companies.	Amount received per 8-c.p. lamp connected. 1891.	1892.	1893.
	s. d.	s. d.	s. d.
Metropolitan	13 7	11 1	—
London Electric	12 3	10 9	—
Charing Cross	16 11	12 5	—
Chelsea	8 4	7 7	6 8
Kensington and Knightsbridge	7 8	7 9	7 5
Notting Hill	8 2	7 3	6 6
St. James and Pall Mall	19 2	15 5	—
Westminster	12 7	9 7	7 9
City of London	—	14 10	13 5
House-to-House	9 3	9 0	7 10

The above results prove the gradual reduction in cost of electricity by economical using. The above districts of London (Kensington, Chelsea, and Notting Hill being residential areas of similar character to Sydenham and Upper Norwood) have about 600,000 lamps connecting with the companies' mains. The cost, however, may be arrived at very accurately on the basis of ¼d. per hour for an 8-c.p. lamp, when the charge for current is 8d. per Board of Trade unit.

Digitized by Google

The preceding statement compiled from my company's books shows the amount actually paid for the supply of electricity during a summer and a winter quarter (Michaelmas and Christmas) of last year, the cases cited being a fair average of the whole. Assuming the consumption for the Lady Day and Midsummer quarters to give similar results, the above return shows that the cost of each 8 c.p. of light installed would be 6s. 2½d. for private houses per annum, 13s. 5¾d. for shops, and 2s. 3½d. for the church."

MULTIPLE TELEPHONY.

At a recent meeting of the Vienna Electro-Technical Society, Mr. Nissl, of the firm of Cjeza and Nissl, read a paper entitled, "A Revolution in Telephony." The paper described a system of telephony whereby one wire can be made to serve several subscribers to an exchange. The principle of the method is stated to be as follows: At a certain point to which a single wire has been carried is arranged clockwork mechanism which causes a shaft to revolve. The speed of this shaft is governed by the number of subscribers' instruments to be served. For instance, in the case of four instruments the shaft would make a complete revolution in one minute. On the circumference of the shaft are arranged contact-pieces upon which feathers slide in such a manner that individual subscribers are brought successively into communication with the exchange for a short period; when the shaft is at rest the connection lasts. Each subscriber is enabled to arrest the rotation of the shaft at any moment when he is in communication with the exchange. Similarly, the exchange can stop the revolving of the shaft. The bringing to rest of the shaft is effected by means of a current passing through an electromagnet which actuates an armature, causing a catch to be inserted in the cogs of a spur-wheel. Arrangements are provided for indicating both to the exchange and to subscribers which contact is sliding under the feather. Further information on the subject is given in the *Zeitschrift für Elektrotechnik* of May 1.

HOW GARNESDON GOT ELECTRICITY.

It may seem to have been a very simple proceeding to those who knew Garnesdon about four years ago—very simple indeed. A company was formed, and an experimental installation was fitted up and successfully run for three months, after which permission was given to the company by the Local Board to light the public streets and supply private consumers.

That is all that seems to have occurred in connection with the successful flotation of the Garnesdon and District Electricity Supply Company, Limited, and if it were not that my conscience troubles me a little during my siestas here in Rosario, that is all that the public would ever know about it, more particularly as the late engineer to the company died a few months ago.

Four years ago I was just out of my time with a firm of electrical engineers, and on the look-out for a chance to add M.I.E.E. to my signature, and at last, in answer to an advertisement for "a young man with knowledge of practical electricity," I got work in Garnesdon.

It seems that the Local Board of that place had had a disagreement with the gas company, and being treated high-handedly, had secured a provisional order for electricity This kept the gas people in order for a while, and in the interim the surveyor and the members of the Electric Light Committee of the Local Board had been bombarded with the tracts and pamphlets of manufacturers of every article that could claim a smiling acquaintanceship with electricity, in addition to which martyrdom in the interests of the community they had felt it only their duty to accept as many invitations to visit central stations and factories as could conveniently be managed, which is a very thirsty and exhausting process, as is well known. The Local Board were a trifle shy about making use themselves of the order, so, as soon as the hospitality of the electrical profession began to wane, the order was turned over, with the consent of the Board of Trade, to a company which had been formed with this result in view. The terms of the transfer included a proviso that the three months' trial should be successfully gone through before the complete ratification of the transfer. This was at the instance of the chairman of the Local Board, who was connected with the gas company. The electricity company thereupon offered to perform the trial upon his own premises, confident that good workmanship and careful operating would convert even a gasman. The offer was accepted, and the immediate result of the negotiations was a first-class dinner to celebrate the first stage of the transfer given by the company to the Board and its wives.

When I came on the scene a week or two after, I found the work of altering a mill on the bank of the river into a central station well in hand. The engineer to the company was a practical mechanic and had a good working knowledge of electricity. He got out the plans of everything, arranging to have the machinery run by turbines, which replaced the old mill wheel. A consulting engineer verified his calculations with regard to the electrical plant, which he had chosen with a view to the utmost simplicity in working. The turbines would drive 110-volt alternators, the current from which would pass from the omnibus bars into low-tension mains for houses in the vicinity of the station, and also into a step-up transformer at 2,100 volts for feeding banked transformers placed where distant groups of houses would require current. House transformers would also be used on this circuit, where the demand was scattered.

I did not find my new e[illegible]h of a sinecure at first, for the board of directors ha[illegible]as and wanted dividends. All the company's shares [illegible]taken up by the board and its immediate rela[illegible]had not been offered publicly. The consequen[illegible]as that the engineer and I became temporarily h[illegible]and wielded shovels, trowels, files, and all the other pretty toys necessary to the erection of an electricity works until the machinery began to come in, when the more congenial task of correctly adjusting it became our lot.

It will been seen that the company was very sure of securing the ratification of the transfer, as, in addition to the elaborate preparations at the station, they had decided to lay the mains underground to the chairman's house. This would, of course, be best for a permanent job, but a much heavier debt would be incurred in the event of the withholding of the transfer than if overhead wires had been used. The conduit consisted of two ducts 2½in. square upon the "Johnstone" system; the high-tension feeders would be drawn into one of these ducts and the low-tension mains into the other. For the present iron drawing-in wires were laid therein, as the cable had not been delivered. There had been a little controversy as to the preferability of twine for this purpose, but it was finally decided to use No. 12 wire, and drawing-in boxes were put down at 100 yards intervals.

The chairman's house was about half a mile off, and was to be lit during the three months' trial without using transformers, this course being considered safer, and the high-tension $^{7}/_{15}$ cable was to be used for the transmission, being plenty large enough to carry the current for the 50-light installation. Everything, at last, being near completion except the wiring of the house, I took that in hand, while the engineer got things shipshape at the station.

My job was a very pleasant one. The household consisted of Mr. Rogers, the chairman of the Local Board, and Evelyn, his daughter, together with an aged housekeeper and the servants. The daughter was a sweet young thing of about 20 and seemed entirely free from the affectation that prevails so generally among women of the middle class. This probably could be accounted for by reason of her mother dying while she was yet a baby, and she had therefore to read the world chiefly through her father's mind; a man, of course, having less finnicking ideas about things than a woman, especially a middle-class woman. The lack of the maternal control could be seen, too, in the whirlwind-like way in which she went about the house. One day I had just started on the drawing-room and was at the top of a ricketty step-ladder behind the door with joy in my heart and in my mouth many nails, when an invisible force com-

Digitized by Google

municated to the door sent the ladder to the other side of the room. I went as well, and performed the latter half of the journey on my head.

When I came to, the housekeeper and Miss Rogers were picking the nails out of my tongue and gums while the servants were standing around with wide open eyes. It was very pleasant for me, especially when the nails came out easily, and I lay there till they were all extracted, listening to words of sorrow and apology from the Rogers girl. I couldn't say much in reply for a long time, by reason of a crucified tongue; and when it was at liberty my efforts at pronunciation were so realistically similar to the immediate effects of a champagne supper that I hailed the doctor's advent with relief, and was straightway ordered off home to go to bed and poultice my mouth.

Next day I felt all right, so started work at the house again. Half-way through the morning a dainty rap sounded on the door. I climbed down hastily from the ladder and opened. The whirlwind was there, looking more like a penitent zephyr, however.

"I am so sorry to have hurt you yesterday," she said. "It was so thoughtless of me not to remember that you were in the room at the time. I hope you are feeling better to-day."

I said something about the pleasure of being made a nine-pin of occasionally, and that she was very kind to risk her fingers between my teeth after the nails.

"And that is what I want to speak to you about," she continued. "Why on earth do you put nails in your mouth?"

I explained that the average man being only possessed of two hands, it had become fashionable among wiremen to utilise the mouth, so as to overcome this lack of foresight in the design of mankind.

"But I'm sure they must taste nastily. Do you wash them first?" she asked.

I assured her that a self-respecting wireman washed his nails morning and night—I did not specify the brand of nails—but promised in future to carry them only in my pocket, to prevent accidents.

After that we used to chat together very often when her father was out. It was well known that he wanted the light to fail during the trial so that he would have a good excuse for withholding the confirmation of the provisional order's transfer; consequently, he did not waste civilities upon myself. But his daughter was very nice, and took an absorbing interest in every item of the work, from the connection leads to the last lamp, and she saved me a lot of trotting up and down ladders to get tools and things. Sometimes she would get inquisitive concerning the inner workings of apparatus and the reasons therefor, whereupon I would stay my hand in its work, sit on top of the ladder like a heathen god on its altar, and tell her all I knew about it. If the day was sultry, the explanation would become very minute and of a Münchausen character; but even on days when the spirit of industry was at its strongest, the sight of a fair maiden, leaning against something that matched her dress and drinking in with upturned face the words of wisdom that came from the topmost rung of the stepladder, was enough to make the description of even a humble ceiling-rose a theme which could not be dismissed under an hour and a half. Oh! it was very nice; and perhaps if the housekeeper had not frequently found excuses for Miss Evelyn's presence elsewhere, I might have been still on that stepladder declaiming the virtues of cut-outs and double-break switches. I noticed then, with sorrow, that old Rogers was extremely unreliable—with regard to returning home, I mean—and could never be absolutely depended on to turn up within an hour either before or after the time at which he was expected. There were some very near squeaks sometimes in consequence of this, but usually when he came round to inspect progress my hammer was making the house echo and the piano was making the hammer feel ashamed of itself.

All jobs, even 50-light jobs, must come to an end at last, but it couldn't be helped under the above conditions and with the unfeeling engineer on pins to start his machines. If it had not been for the vital importance of the trial, I fancy that the cut-outs in the house of Rogers would have needed pretty frequent repairs; but I nobly withstood the temptation to put weak fuses in, and thus risked the chance of not seeing so much of Evelyn.

However, fortune favours the virtuous, and it was a weird day during the next few months that we didn't manage to run across one another "quite promiscuous like" on the high road or in one of the pretty meadow paths in the vicinity. Old Rogers was understood to be very wroth when these meetings reached his ears, but his daughter had a will of her own and— well, perhaps he knew her better than I did.

As soon as the house was finished and the last connection made to the station switchboard, we saw all clear in the dynamo-house, put a tub of salted water into the circuit, and opened the turbine gate. The main switch at the house had been previously closed, so that we had just the line and resistance in circuit, and great was our joy to find the voltmeter finger point to 110 as we gradually lessened the resistance. Next day the trial commenced in earnest, from sunset to midnight, as agreed upon, and everything ran sweetly.

It was very easy work now, and would be till the end of the trial, when, if successful, we should put down two more 25-kilowatt alternators; mains would have to be laid throughout the compulsory area, and transformers put down—one at each side of the upper town and three in the lower.

One day I persuaded Evelyn to visit the works, and introduced her to the engineer, who showed her all over the place and quite eclipsed the glories of her scientific experiments on making switches spark at home, by letting her work the adjusting screws of an arc light frame which he had put together while we ran the exciter on to its terminals. After that she often dropped in, and learnt the names and uses of everything in the station. She was very useful, too, at times; when an instrument would require tinkering up, her delicate fingers would make short work of what to either of us would have been a most sweatful and laborious job, provocative of free and easy blasphemy. In fact, she got so eaten up with the attractions of the works that we had to keep our eyes perpetually on her to prevent her from opening the turbine gate when the machine was on dead short-circuit or from making impossible joints on spare cable, which process stained her dress and ruined the whiteness of her fingers.

All went well at the works for about nine weeks. No complaints had been made of the light not being bright or of it flickering, which was not very strange, even when old Rogers played the goat with the big electrolier switch, evidently to try and jerk something wrong, as Evelyn would tell us; we always ran the alternator at nearly its maximum speed, and the excess current went into the salt-water tub, which was an effective deadener and cost us nothing more. We got so cocksure of ultimate success at last, that we sometimes dispensed with preliminary runs before sunset and only started our machines when twilight came. This only happened if we were both away during the day, as sometimes happened if there was something on in the neighbourhood such as a picnic or an agricultural show, when we would lock up the place early in the day and get back before sundown. In fact, it was so deadly slow just then that we may be excused for getting out of sight of sleepy Garnesdon occasionally. There was little to do beyond testing the machinery and the circuit, and this duty was usually performed about mid-day, and was sometimes witnessed by members of the Local Board passing at the time. Old Rogers, the chairman, often looked in during these operations and picked his teeth meditatively. Once he dropped his silver toothpick near the alternator and the engineer swore that he tried to drop it into the field, and ever afterwards kept a wary eye upon him.

One day a grand Primrose League garden party was to be given at Storton, about 15 miles away, which was the event of the year. People came to it from all parts of the county, but it was very select. Evelyn had told me that she was going, but that her father would have to go to London that day. This was maddening to me, who, of course, had not been invited. The engineer's best girl was also going, and as her parents were not sure of accompanying her, it was likely that the two girls would drive down together. Consequently the engineer and I were in a very vicious state of mind, and on the morning we awoke with heavy hearts rather earlier than usual. I went to my window to see if our charitable prayers for wet, streaming, dismal weather were going to be answered, but was disappointed. The early morning sun was shining with a stolid German perseverance that betokened a cloudless day. Coming down the road was Mr. Rogers,

Digitized by Google

with a bag in his hand, looking very flushed and heated, and evidently on his way to the railway station. No one else was in sight as far as I could see from behind a crack in the blind. Within 20 yards of the works he stopped behind the hedge and wiped his perspiring face with his handkerchief and then fanned himself vigorously. I still watched curiously; it was such an odd thing for a man to do after a five or ten minutes' walk from his house. At last he resumed his journey, evidently feeling less heated, but instead of passing on he went to our gate and pulled heavily at the bell. I slipped on a dressing gown and went downstairs wondering what could have happened to the light the night before. He was just giving the bell another tug and seemed surprised at my prompt appearance.

"Good morning," he said. "You sleep lightly, young man. I've got some spare tickets for the Storton garden party to-day, and if you and your chief would like to attend it you are welcome to a couple."

I thanked him with fervour, and he continued: "My daughter and Miss Hearne are going down in the trap, and as it might be awkward for you to get there by yourselves, you have my permission to drive them down. You or Mr. Holloway can drive, I suppose?"

I said "yes," but I meant dynamos.

"Well," he said, "don't start later than nine or you'll miss the luncheon. You can return in the trap when you please for your duties here and have it sent back for the ladies."

I was redolent with gratitude and invited him inside to endure the pouring forth of similar sentiments from the engineer.

"No, thank you," he replied. "I only just have time to catch my train. Hope you'll have a pleasant time; you hard-working fellows deserve it. Good-bye," and with that he was off.

The engineer had heard the conversation, and when I burst into his room had forsaken dignity and bedclothes, and was standing on his head.

"Well, I'm blowed!" he exclaimed, finally resuming the respectability of the horizontal plane. "I never credited the man with being anything better that a pirate with a pretty daughter. My conscience, won't we enjoy our young selves?"

I told him of the long time old Rogers had stayed outside before calling, and how inexplicably hot he semed to be, but the only conclusion we could arrive at was that he had had to call somewhere else after leaving his house, and was perhaps too regardful of his dignity to call upon us in his then state of towzled perspiration. At any rate we hadn't much time to waste talking, and our looking-glasses were pretty busy during the next half-hour or so. Breakfasted as usual at the King's Arms, and started for the house in good time. The girls were both ready, and off we went: the engineer and Miss Hearne on the box seat and Evelyn and myself behind.

Of the beautiful time we had that day it is not necessary for me to speak. The programme thereof may sufficiently indicate it. Luncheon, tennis, tête-à-tête, dinner, croquet, tête-à-tête, refreshments, boating, tête-à-tête. Then it was time for the engineer and myself to come away; the more especially as Evelyn had told us that a little dinner party was to be held at the house that evening, and the lights would be coming on early. Her father had told her to please herself about attending the dinner, as it was a purely masculine gathering, but she decided to return, as did Miss Hearne, which was so much nicer for us two men.

The return journey was too soon over; we dropped Miss Hearne at a house just outside the town and drove straight through to the works, as Evelyn wished to see the machinery started. It was only about half-an-hour to sunset, and as we approached our destination we noted the rustic beauty of the immediate neighbourhood of the transmogrified mill, the dazzling glory of the setting orb, and the general peace and quietness that prevailed. The engineer waxed cynically practical; "It's a good job for us the sun does set sometimes," he remarked, "precious little electric light would be wanted if it didn't."

Evelyn said that he reminded her of a depraved man her father knew, who built fire-engines and saw no beauty in other than wooden houses.

When we got to the works we were nearly stifled by the heat inside. The baking sun had been pouring down on the roof of the dynamo-house all day, and had converted it into a first-class oven. We opened the windows and sat down by the switchboard. Evelyn said, "I *should* like to start your machines to-night. I'm sure I could manage it all right."

Evelyn's desires were usually laws to us so, though it was too early to start, I went to the sluice valve and polished the wheel with some waste, adjusted the resistance for no load and stood by while she screwed the valve wheel round slowly, watching with evident delight the gradual revolving of shafting and increasing hum of the alternator and exciter.

"Whoa!" suddenly shouted the engineer rather impolitely. "Turn it back, quick!" You'll burn the blessed things up!"

I looked around. Sure enough the armatures were revolving at an alarming rate, and yet the valve wheel was not sufficiently unscrewed to account for this. Evelyn reversed the wheel and we looked at the voltmeter, which read *nothing!!* This was strange, since even then the tachometer was reaching 150, and I went round to all the connections and switches to find the cause of this open circuit. Everything seemed right, and, in response to my look of enquiry, the engineer whistled the ⌒⌣-like whistle of a man in doubt.

"Do you think that your man has forgotten to close the main switch at your house?" he asked Evelyn, "or perhaps he has opened it too soon?"

"I don't think so," she replied; "Henry is such a methodical man. But I will drive there and see."

"Thank you," said the engineer. "You had better go, too, Tom, and see if the fault is at that end of the line. Make haste back if it isn't."

I helped Evelyn into the trap, and we drove at a breakneck pace to the house and went through the side gate to the switchboard shed. The switch was closed, as we had arranged to always have it during the day to enable us to test the line properly, and the ends of the cable were securely sweated into the thimbles at the back! A hasty glance assured us of both these facts, and a growing conviction that the trouble was on the line forced itself upon me. Evelyn grasped the situation immediately, like a true woman.

"Come back to the works," she exclaimed, "and see what is to be done"; and we got into the trap again and went back at full gallop.

Evelyn was quite as excited as I was, and seemed to realise as plainly the probable consequences of a non-supply of the light.

"I hope you will find what is wrong," she said. "Three of the men coming to dinner to-night are on the Local Board, and two of the others are connected with the gas company—directors, or something; and you can imagine what they will say if the light fails. Even if you never have another accident in the three months, the possibility of such a thing happening will be apparent to them, especially now when all is in your favour at the works."

I groaned inwardly and cursed the Primrose League, and all that therein is, which had led us away from the path of rectitude and of regular machinery testing. The horse would have cursed the Primrose League, too, if he could have traced to that body the reason for the wild slashing he got till the works were reached.

"Well," anxiously enquired the engineer, who was waiting outside; "anything wrong at the switchboard there?"

"No," I answered; "it must be a break on the line, I'm afraid."

"My conscience! A break on that 2,000 meg. concentric! Not the sign of a leak yesterday, was there?"

"Not a scrap. Shall I go out and try to find it?" I asked him.

"I don't fancy there's time," looking at his watch and then at the sun setting through the trees. "Even if you found it immediately, which there isn't much chance of doing, it would take you the best part of a day to make anything of a job of the thing. Must be a pretty clean break, you know, or part of the outer concentric would have given us some kind of return."

"And we haven't got a piece of spare cable over 20 yards long," I said, after rumaging through the storeroom. "We should just have time to run it over the fields to the house if we had; though it would not help matters much if Mr. Rogers got to know that we had to use makeshifts."

Digitized by Google

Evelyn had been peering in among the stores, too. "Why won't that do?" she asked, pointing to the length of drawing-in wire which had been coiled on a drum after being used to get the cable through the conduit. I was about to explain to her in a superior masculine manner that it wouldn't carry the current, when the engineer said, *con expressione*, "By Jove, the girl's right," and straightway got out his pocket-book and began figuring rapidly therein.

"There," he said, at last, "we'll fix the thing yet; but first, Miss Evelyn, can you tell me if there would be any chance of making a fresh connection to the switchboard at your house and of putting down one of those transformers there," pointing to a recently-delivered batch of house transformers, "without your father hearing of it?"

I saw his point now, and felt inexpressibly relieved when Evelyn promised to keep the servants out of the way at the house while things were fixed up in the shed. We should have to trust to luck not to meet anyone on the way.

"You're a dear girl," said the engineer, evidently relieved, and then he unfolded his plans to us. The step-up transformer, which luckily had arrived, would transform the voltage to 2,100, and the drawing-in wire would carry nearly two amperes without risk of undue heating. As only about 1,700 watts was the maximum power that could be taken by the house, and 1,200 a strong average amount, there seemed every reason for thinking that the arrangement would work out all right in practice.

We had no time to lose now, so set to work to mount the drum on a truck, with the transformer on a board between the shafts, and Evelyn set off for the house to get things ready for its reception. We fastened one end of the wire to a tree at the side of the works, and then, no one being about, the engineer trailed the wire along the top of the parched hedge while I pulled the truck along. Although there were a great many twists in the road, there was not a break in the continuity of the hedge except for an occasional stile, a series of meadows being between the works and the house on that side of the road and a few big houses on the other. We got along splendidly till within a short distance of the house, when we found that the wire would hardly be enough, if we followed the course of the hedge, on account of the windings of the highway, so we decided to cut across the meadow to save going back for more wire. We had to wait five precious minutes, however, while a loving couple meandered down the road one behind the other, after the approved style of those in humble life whose love is too deep for words. We cursed them in our hearts as they stared foolishly at the truck and at the engineer on the other side of the hedge with a sack cast over the drum, and felt relieved when they had gone out of sight round a bend trusting they had seen nothing incriminatory to gossip about. Then we laid the wire along the grass, propping it up with twigs as we went, though the grass itself was dry as tinder after the heat of the day. The end of the wire we threw over the side wall, as near to the shed as we could judge, and then returned to the road, the engineer to return to the works to fix up things, and I to take the transformer to the side gate, where Evelyn was waiting anxiously. By the interest she was taking in the swindle one would never have thought that she was helping to undermine her father's business, and, of course, do no good to herself financially. But then she was a woman, you know.

No one was about, so I got the transformer into the shed safely and brought the end of the wire in through a crack in the roof. Evelyn became jubilant. "I have told Henry that I've opened the switch," she said, with an unaccountable pride in the success of the lie, "so he won't come out here to-night. Can I help you?"

I did not need help to disconnect the house wires from the switchboard, twist them to the low-tension side of the transformer, and the drawing-in wire to one of its high-tension terminals, but I was rather puzzled and anxious about making a good enough earth. When, however, I told Evelyn what I wanted, she showed me the earthed end of the lightning conductor, and that job was soon over.

Before I went back to the works I wilfully wasted a couple of minutes telling her what I thought of her goodness and devotion to our cause, what my friend the engineer thought of it, and what all right-minded people would think of it if ever they got to know. In fact, I should have stayed there all night babbling gratitude if she had not reminded me that the engineer might want me, and that we were not yet out of the wood.

I tore myself away and hurried back with the truck, pleased to observe that the wire was almost invisible on the hedge and calculated that it would be entirely so after dark. I found the engineer connecting a cable from one of the dynamo brushes to a choice collection of pickheads and crowbars that he had driven deep into a shallow pool at the rear of the works, and to the other brush was connected the drawing-in wire. I told him how things were situated at the house.

"Well," he said, "as long as the night keeps dry I don't think we have much to fear, but heaven help us if there is much of a dew or it rains. Mica hedges wouldn't be any good then. And, another thing, if anybody goes through that hedge to-night, there'll be the other after-world to pay. Still, we must risk it now."

I agreed with him; we were so wrapped up in the affair and the hope of its successful termination, that I half believe we would have risked our immortal souls to bring this about.

The sun was well below the horizon now, so after seeing everything in order and hastily muttering a prayer to the *deus ex machina*, the machines were started.

To our joy the voltmeter finger moved around the dial as the sluice valve was opened, and with a heavy artificial resistance in circuit stood at 102. When the resistance was reduced the machine gave almost its normal output, so that we had no fear of having to overrun it and risk the armature coils. After a time the load began to come on and I went outside to see how the wire bore it. There was no apparent heating, a light breeze keeping the temperature down. Then, as the engineer had things well in hand, I took a couple of hooks and commenced an inspection of the road boxes, of which there were eleven between the house and the works. It was hard work getting off the covers single-handed; dirt had been wedged in which, with the red lead packing and the weight of the cover itself filled in with concrete, made me appreciate the evening breeze. At nine of the boxes I could find nothing to indicate a break in the cable, and as it was now quite dark I began to fear it would have to be a hauling out job. When I tackled the tenth box, which was situated at a kind of double bend in the road close to the house, it came up very easily, nearly throwing me backwards on my head. I struck a match and looked inside, and a glance explained the loose cover—and several other things eventually—for the cable had been rudely hacked asunder just where the conduit entered the box. There could be no doubt but that it was an intentional deed. The works' end of the cable hung over the hedge of the conduit, but did not touch the bottom of the box.

I sat down with my legs in the box, trying to think who had done this, but had to give the puzzle up at last, and was cogitating ruefully what a deucedly awkward thing a concentric was to splice, and how doubly deucedly awkward the operation would be if there was not enough slack to enable it to be got at properly, when I heard someone coming along the road. I did not move till I heard the footsteps stop, and then quickly retrace themselves, and when I looked up the owner of the feet had disappeared around the bend again. I thought it very strange, but concluded that it was some timid person who saw me sitting in the road, and took me to be either an accident or a highwayman, and after a few minutes' meditation I got up and replaced the cover. Just as I was stamping it down, I heard a hoarse, quick cry seemingly not far off.

"My goodness," I thought, "if it's anybody messing about that hedge," and ran in the direction of the sound. There was no one in sight down the road either way, so, as the hedge was very thick, I went for the nearest stile, and looked into the field. Some little distance along, close to the hedge, I could see the form of a man lying down, and as I drew near I went sick with apprehension as I recognised the spot where the wire branched off from the hedge across the field. This, and the contracted posture of the body, made me fear the worst.

Before touching him I ascertained the whereabouts of the wire, and found that he had evidently stumbled over and beyond it in his fall. I stepped cautiously over it and turned the man on his back, realising my morbid expectations. The

Digitized by Google

man was dead! And as I bent over him I recognised the features of old Rogers.

At first I would not believe my eyes; the facial muscles had contracted, a froth had issued from the lips, and the semi-darkness may have deceived my physiognomical memory, but there was no mistaking the inevitable black bag and the massive gold chain with the cross and locket dangling therefrom. I think I may say, with some degree of truth, that the unfortunate event somewhat awed and perplexed me—perhaps because I was younger then. Why was old Rogers behind the hedge at that time of night? and what was to be done in the present state of affairs?

A dim, religious light began to dawn upon me with regard to the first problem. From the position of his body, he was evidently returning to his house from the railway station. Could it be that his were the footsteps that retraced themselves at the bend of the road a short time previously, and had he then got over a stile and walked noiselessly along the field, past where I was sitting in the road, till he came in contact with the deadly wire as it left the hedge? And if so, what was the reason for this strange proceeding?

There seemed only one way to account for it; ordinary timidity did not fill the bill. A guilty conscience needs no accuser, and he had evidently recognised me sitting in the road box where the broken cable was, and had avoided meeting me. Now I saw why he had come down the road to the station in the morning flushed and heated, and had waited to cool off before seeing us; why he became so suddenly generous with the garden party tickets; and as I picked up his bag, which was securely locked, and shook it, the weight and the muffled jingle of metal inside told me plainer than a provisional specification could have done in a month that a hammer, cold chisel, and perhaps some kind of appliance for lifting the lid of the road box, were wrapped in newspapers inside. That settled me in my resolve to let his death remain as much of a mystery as possible, and I stepped back across the wire and made for the works. The wire as it passed the stile had been carefully hidden out of sight and easy reach, so that there was no danger in crossing it. I passed a few people on my way back, but felt sure that no one could see the body from the road.

"Found the break?" queried the engineer, as I came panting in.

"Yes," I replied; "and the breaker."

"Good business; let's hear about it."

I sat down and explained the state of affairs. The engineer's eyes opened and his face grew longer in orthodox manner as the tale of woe proceeded. "Shall we go to the police station and give ourselves up?" I asked in conclusion.

"Not much," said the engineer, after reflection; "it's just a judgment of Providence on the man. I don't think we need say anything about it."

"Don't you think the doctors will find out the cause of his death at the post-mortem? Providence doesn't own an electricity works in Garnesdon, you know."

"We must chance that," said the engineer; "besides it is very unlikely that the small current could do all that mischief. He was subject to fits or something internal, wasn't he? and probably the shock just helped one along."

I remembered Evelyn telling me that her father suffered from heart disease, so that cheered us up a little. "How rummy the place looks, lit with lamps and candles," I observed.

The engineer smiled too. "Yes, I was afraid to tinker with the circuit to-night to light us up here. By the way, the voltmeter gave an odd jump about twenty minutes ago, but I thought it was the big electrolier switch being played with. It must have been poor old Rogers giving up the ghost. I shall be glad when twelve o'clock comes, and we can take that wire in out of sight," he mused. "Wonder what the guests will think of his non-appearance, and if his plucky little daughter will guess what's happened."

I felt very sick, for Evelyn's sake. Believe me, it is never nice to discover oneself to be a murderer, and the unpleasant feeling is in no degree modified when the murdered man happens to be the father of the girl one loves. This unfortunate mental condition will prevail even when strong extenuation exists in the fact that the deceased was an electrophobian gasman.

And if Evelyn did discover how her father met his death, I suppose that I should have to feel very sick for my own sake; unless, indeed, she reciprocated the affection I entertained for her to a greater extent than at the time I thought possible. These thoughts and occasional attention to the machinery helped to pass the time away.

About ten o'clock a vehicle stopped outside, and the engineer rushed to the door, unwilling that anyone should come into the station in its present condition, shut the door after him, and went to the outer gate. Some conversation ensued with the occupants of the trap, and then it was driven off. Presently he came in again.

"They've missed him at the house," he said. "The guests got tired of waiting for him to turn up, so dined with the two ladies and looked in here on their way home to see if we had heard anything of him. They fancy he must have been detained in London, but the housekeeper thinks he has had a touch of heart disease; and that's how matters stand to the outer world at present. I don't think they are likely to take any steps till the morning, and in the meantime we can get that wire in out of the way."

Midnight came in due course, and we shut off. I went up the road to the house and cut the wire outside the garden wall, intending to call in on the morrow and remove all traces inside the place. As I returned, coiling the wire up, I found the engineer bending over the body, examining it.

"See where it touched him," he whispered; "just on the back of the wrist. He must have been stooping pretty low at the time, and the shock made him jump right over it. Funny-looking brown mark, isn't it?" as he struck a match to see it clearly.

We turned the body over into its original position and came away. Not a soul was out at that time of night, and we got the wire all in and went to bed worn out with the events of the day. Neither of us slept much that night, and we got up early in the morning to prepare our jointing and vulcanising tools, expecting to hear every moment of the discovery of the body. The road was not a very much frequented one, and it was nearly nine o'clock before a man came rushing past on his way to the town. Ten minutes after, a cab containing a doctor and several policemen tore back towards the fatal spot, the loafers of the town bringing up the rear, eager to gratify that pardonable curiosity which helps to distinguish mankind from the lower animal world. We carefully enquired what was the matter before joining in the rush, but when we arrived at the scene of the tragedy the body had already been carried into the house, and the late arrivals were growling as if they had booked high-priced seats to view the spectacle. The more fortunate ones described unctuously the appearance of the body, with elaborations, and said the doctor's opinion was that deceased had had a fit on his way home from the station the night before; and though the police were at first suspicious of foul play, in consideration of the peculiar situation of the body, they eventually came to the same conclusion on finding all his valuables intact.

Nothing more would be known about it till the inquest, but so far things looked as favourably for us as could be expected.

We did not feel like going to the house that morning, so trusted to the general excitement there that the shed would not be visited and set to work on the broken cable. Luckily, there was some slack in the drawing-in boxes on either side of the one tampered with, and, as the cable had been well greased when drawn in, we managed to haul enough along to make operations easier. People came up by dozens that day to view the spot where the body was found, which was guarded by a policeman till the coroner's jury should have seen it, and we had to rig up a tarpaulin shed to keep prying eyes from seeing too clearly the nature of our work in the box. The joint was finished that afternoon, though an experienced jointer at a shilling an hour would have probably taken a day over it.

Late in the afternoon I went to the house to proffer my sincere sympathy to Evelyn. She came down from her room on hearing who it was; her eyes red, but keeping up bravely. We only spoke about the sad bereavement at first, till, seeing that she had forgotten the operations of the night before, I enquired if I might go to the shed.

"Oh, yes," she exclaimed, her memory coming back to her. "I am so glad to say that the light was just as usual last night. Only once it seemed to go rather dull, but it was

Digitized by Google

not noticed by any of the visitors. I hope you will find it all right in the shed."

I bade her good-bye for the present, and went out to the switchboard wondering what she would have said or done if she had known the cause of the light going "rather dull." The necessary disconnections were soon made, the end of the wire hauled into the shed and the transformer put in a corner ready for use, if required when the trial was over. Now that all trace of our operations had been destroyed and the circuit was in working order again, with the only man likely to destroy it out of the world, a successful ending to our endeavours seemed quite possible.

The dreaded inquest passed off very successfully—at least, from our point of view; though one of the doctors contended that lightning was the primary cause of death, heart disease supervening. No lightning, however, having been observed on the night in question, this opinion was overruled by the other doctors called in, who naturally enough preferred to attribute the effect to the most likely of doubtful causes, and the verdict was "Death from natural causes."

No one seemed to worry about the nature of the tools found in the black bag, and in due time the funeral came off and was attended by hundreds of people. All grades of sorrow were represented at the graveside—from the sorrowful sorrow of those who loved the man to the simulated sorrow of distant relations whose thoughts wandered away to the probable contents of the will—and, hypocrites though the latter were, they could have been safely given 50 points in 100 at that game by a couple of lachrymose-looking young men who were frequently convulsed by the effect of their own emotions.

After the ceremony we breathed freer, and slept at night for quite hours at a time. It was also possible for us to eat meat suppers again without being responsible for injurious effects upon the nerves of late wayfarers passing the station and of tramps who slept under neighbouring hayricks.

The provisional order was formally handed over to the company at the expiry of the three months' run, and now that district is one of the best lighted in the provinces. I see from the English electrical papers sent out to me that the total cost per unit is well within 3½d., so that it must be a good thing for the company at 7d. delivered. What it might have been if the late lamented chairman of the Local Board had caught an earlier train home on the night of his death, can only be judged by his actions earlier in the day.

As I have mentioned, the engineer is dead—got drowned in the river while in charge of the works, and I am here in South America.

Oh, yes, about Evelyn—I mean Lady Fitz-something or other. She found herself left so well provided for, and was so much sought after by the eligible aristocracy and needy nobility of the county, that—well, you know women, don't you?

PHYSICAL SOCIETY.

At a meeting on the 27th ult., Prof. A. W. Rücker, F.R.S., president, in the chair, a paper "**On the Mechanism of Electrical Conduction: Part I., Conduction in Metals**," was read by **C. V. Burton, D.Sc.** Considering a body not at absolute zero of temperature, the author shows that electromagnetic radiation would result in heat being degraded into a lower form of energy if any parts of finite electric conductivity were present, and from the fact that our planet is not devoid of heat deduces the following Theorem I.: "In a region containing matter there may be (and probably always are) some parts which are perfect insulators and some parts which are perfect conductors, but there can be no parts whose conductivity is finite unless every finitely conductive portion is enclosed by a perfectly conductive envelope." This conclusion is in accordance with Poisson's theory of dielectrics, and with Ampère's and Weber's theories of magnetism and diamagnetism respectively. Theorem II. is enunciated as follows: "In metals, and in other non-electrolytes whose conductivity is finite, the transmission of currents must be effected by the intermittent contact of perfectly conductive particles," and as a corollary Theorem III. is given: "If we suppose that in a substance at the absolute zero of temperature there is no relative motion amongst the molecules or amongst their appreciable parts, it follows that every substance at this temperature must have either infinite specific resistance (which does not imply infinite dielectric strength) or infinite conductivity." Fleming and Dewar's experiments on pure metals tend to confirm this. The author then shows why, on the intermittent contact hypothesis, a conductor is heated when a current flows through it. On the assumption that in ordinary conductors the relation between the electromotive intensity in the intermolecular spaces and electric displacement is a linear one, and that the electric forces are small in comparison with the ordinary intermolecular forces, Ohm's law is deduced. A model is next described, by means of which contact E.M.F. and the Peltier effect can be represented and explained; and in considering Volta E.M.F.'s, the author points out that it is doubtful whether experiments in a perfect vacuum could decide the questions at issue in the contact-force controversy. The fact that the transparency of metals is much greater than Maxwell's theory indicates might be explained without attributing any new properties to the electromagnetic field by supposing the dimensions of molecules not quite negligible in comparison with the wavelength of light. **Prof. S. P. Thompson** thought the paper had an important bearing on the kinetic theory of solids. He saw no reason why Ohm's law should be proved, for he regarded it as a definition. The **President** said the author represented all actions as being due to collisions, thereby introducing the same difficulties as were felt in the kinetic theory of gases—viz., that collisions would give rise to mechanical oscillations in the molecules of shriller and shriller pitch. After some remarks on the invisibility of molecules by **Mr. Hovenden, Dr. Burton**, in reply to Prof. Thompson, said Ohm's law when expressed as $\frac{E}{C}$ = a constant, was really a law, and not a mere definition.

A communication "**On the Design and Winding Alternate-Current Electromagnets**," by **Silvanus P. Thompson, D.Sc., F.R.S.**, and **Miles Walker**, was read by the former. The paper describes experiments showing that when the magnetic induction does not exceed 4,000 C.G.S., the pull exerted by a laminated electromagnet on its armature is the same whether it be excited by continuous or by an alternating current of equal strength. For higher induction the continuous current gives slightly greater force. Another experiment made with solenoids and the U-shaped plunger of a Brush alternate-current arc lamp, gave similar results. In considering the question of winding alternate-current electromagnets so as to obtain a given excitation when the current is supplied at constant voltage, it is shown that the ampere-turns are inversely proportional to the number of turns, for the impedance varies nearly as the square of the number of turns. One important property of such alternate electromagnets when supplied at constant voltage is that they give a fairly constant pull over a long range, for as the armature moves away from the magnet the current increases, thus counteracting to some extent the effect of distance. On the other hand, the alternating voltage required to obtain a given force is much greater than that needed with continuous currents. With the armature in contact with the core the ratio of the two voltages was found to be 170, whilst separating them by 9·2mm. reduced the ratio to 21·5. **Prof. Perry** pointed out that the constant pull of the alternate-current magnet followed immediately from the fundamental equation $e = re + n\dot{I}$, when re is small, for if e be constant, then $\dot{I}$ and therefore I and I^2 are constant. He was interested to see that the pulls for equal ampere-turns were the same, and indicated how the problem would be worked out mathematically when hysteresis was taken into account. **Mr. Blakesley** thought it better to fill well this space on a magnet full of copper rather than use wire only just large enough to carry the current, for the loss of energy would be reduced. Some of the formulæ given might be put in simpler form. **Mr. Swinburne** said an alternate-current magnet would only give constant pull in special cases. As another rule for winding alternate-current magnets, he said, wind the magnets as for continuous currents and put a condenser in to take the same current, thereby reducing the voltage required. **Mr. Blakesley** said it would require a capacity of 600 microfarads to suit the magnet mentioned in the paper. **Dr. Thompson**, in reply, agreed with Mr. Blakesley that the condenser was impracticable in many cases.

Major R. L. Hippisley, R.E., read a paper on "**A Graphical Method of Constructing the Curves of Current in Electromagnets and Transformers**," and exhibited a machine for drawing these curves. Taking the ordinary equation for a simple alternate-current circuit, $E \sin pt - \frac{dB}{dt} = Ri$, where B is the total magnetic flux, and i the current, the author writes it in the form $E \sin pt - mk L \frac{di}{dt} = Ri$, where L is the coefficient of self-induction of the circuit with the iron withdrawn, and mk the tangent of the inclination of the B H curve at the point corresponding to the instant considered. This equation is integrated for a short part of the cycle, during which m may be considered constant, giving $i = \frac{E}{R} \cos \theta k \sin (pt - \theta k) + Ak e - \frac{Rt}{mk L}$. Methods of finding the constants in the last equation are then described, and the method of drawing the current curves step by step explained. The machine for performing the process is illustrated in the paper, and the curve for an electromagnet fed with alternating current shown. The case of a transformer without magnetic leakage is worked out at some length, and the curves of primary and secondary current determined. **Dr. Sumpner** said the author had used great care in working out a difficult problem more completely than usual. In cases such as arise in practice, the R i term is small, and for this case Evershed showed how to determine the current curves of a transformer when the periodic state had been reached some five or six years ago. He (Dr. Sumpner) had also shown how to graphically determine the current curves for circuits containing iron in 1888. The author's method was, however, of more general application. **Mr. Trotter** enquired whether the machine could be used in practical alternate-current problems, say, for example, to pre-

Digitized by Google

determine the E.M.F. curve of an alternator. **Major Hippisley** replied to the points raised.

LEGAL INTELLIGENCE.

DE LIVET v. OLIVER AND OTHERS.

In the Chancery Division of the High Court of Justice, last Friday, Mr. Justice Chitty had before him the action De Livet *v.* Oliver and others, in the shape of an application by the plaintiff for an interim injunction to restrain the defendants, until allotment to the plaintiff of 470,000 fully-paid £1 shares in the British Steam Generator and Refuse Utilisation Company, Limited, from selling, disposing of, or using the patent of the late C. de Livet.

It was stated that the plaintiff was the widow and personal representative of M. de Livet, who had invented and patented a means for burning and using refuse. Before his death, which occurred in August, 1893, he entered into an agreement with the defendants Oliver, Sheridan, and Houldsworth for the purpose of forming a company to buy and work his invention. After his death an agreement was made between the plaintiff and the three defendants and the above-named company for the sale to the company of the invention, in consideration of the allotment of the shares in question to the plaintiff, to be held by her in regard to some two-fifths thereof for herself, and as regards the remainder for other persons. In March, 1894, the defendants entered into an agreement with a syndicate called the Atlas Syndicate, for the formation of a subsidiary company for the purposes of taking and working a limited assignment of the patent within London and 20 miles round. The plaintiff stated that the shares in the original company had not been allotted to her, and claimed an injunction accordingly.

His **Lordship** said that the plantiff had a lien which she could enforce. He saw no reason for not applying the ordinary doctrine of vendors' lien. But, apart from that, it was agreed that she should have the shares at once. The plaintiff was entitled to an injunction as asked, until trial or further order, with costs in any event.

COMPANIES' MEETINGS.

SUBMARINE CABLES TRUST.

The twenty-third ordinary annual meeting of the certificate-holders in the Submarine Cables Trust was held last week at Winchester House, the Marquis of Tweeddale presiding.

The **Chairman** said the revenue for the past 12 months amounted to £22,593, as compared with £23,102 in the preceding year, showing a decrease of £509. This decrease was due to their having received a smaller dividend during the year from their investment in the Anglo-American Telegraph Company. He regretted to say that there was no visible improvement in the traffic on the Atlantic, and he feared that their income from that source was likely to suffer for some time to come. The expenditure for the year totalled £1,301, as against £1,627, showing a decrease of £326. This diminution was mainly owing to a reduction in the number of the trustees consequent upon the lamented death of their late colleague, Sir J. Anderson. The cost of administering the trust was £698 under the amount provided by the trust deed. The revenue during the past year was sufficient to meet two coupons of £3 each, and to pay an additional 5s. on the overdue coupon. There still remained £1. 5s. in arrear, which they hoped to pay in about July next. Although the traffic in the Atlantic was very low at present, they must hope that with a return of business it would improve, in which case their income would be in a very satisfactory condition. In conclusion, the Chairman moved the adoption of the report.

Mr. J. D. Pender seconded the resolution, which was carried.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.

The thirty-fourth ordinary general meeting of the West India and Panama Telegraph Company, Limited, was held on Wednesday at Winchester House, Mr. C. W. Earle presiding.

The **Chairman** said the result of the year's operations had been that they had received £4,093 less than in the corresponding period last year, and their expenses had been £2,553 less. As they were paying 3d. more on the ordinary shares, it might be asked how, seeing the net result was a reduction of £1,540, they could afford to do so. The explanation was that during the first six months of last year they had a windfall of about £2,000 by the interruption for seven weeks of their competitor, the French cable, between Hayti and Cuba. In the present half-year they had been able to estimate the outcome of the half-year, and, looking to the saving they would make from their second ship being in dock, and not costing more than about £400 a year, they thought they would be quite able to keep up the dividend on the current half-year as at present recommended. The Chairman then referred to the great advancement made in the code system, and said the West Indian merchant now saved half the expenditure that it cost him to telegraph 10 years ago. He moved the adoption of the report and accounts and the declaration of the following dividends for the six months to December 31: 6s. per share on the first and second preference shares, and 9d., free of income tax, on the ordinary hares.

The motion was carried.

LONDON ELECTRIC SUPPLY CORPORATION, LIMITED.

Report of the directors and statement of accounts for the year ending December 31, 1893, presented to the shareholders at the seventh ordinary general meeting held at the offices of the Corporation, 3, Adelphi-terrace, W.C., on Wednesday last.

The reports of Dr. Fleming and the engineer, appended hereto, describe the works that have been carried out during the year, and the general condition of the Company's station and plant. During the short time the new transformers have been in use their greater efficiency has sensibly decreased the loss of current. When the whole of them are installed, a considerable advantage will arise from the increase in the proportion of saleable current to current generated. The other important new works described in the engineer's report have proved beneficial, and have materially increased the efficiency of the system of supply. The increase in the number of lights during the year is stated in the engineer's report, and amounts to about 34 per cent. But for the general depression of trade, the rate of increase, which was most marked in the first half of the year, would doubtless have been greater. The result of the year's working shows an improvement on previous years, the revenue account showing a small balance to the good, as against a loss of £3,914. 9s. 7d. last year; and this notwithstanding the reduction of the standard charge to 6d. per unit, and the severe and continuing competition in the best districts of the Company's area of supply. In view of the growing increase in the use of electricity, and of ensuring uninterrupted continuity of supply to consumers, the Board recommend that a new generating unit of 1,250 h.p. be provided as speedily as may be. This, with the necessary apparatus for connecting new customers, will, however, involve a further extension and expenditure of capital. Mr. Francis Ince has retired from the Board. The directors retiring by rotation are Mr. Joseph Pyke and Major C. B. Waller, who, being eligible, offer themselves for re-election. The auditors, Messrs. Kemp, Ford, and Co., who retire in accordance with the articles of association, offer themselves for re-election.

Engineer's Report.—I have the pleasure to report that during the past year the Company's consumers have received a more satisfactory supply of electric energy; the working of the year as a whole, showing a distinct improvement on all previous years, both with regard to the steadiness of the light and the continuity of supply. We commenced the year with a connection of 46,197 lights; at the end of the year the number had increased to 61,924. But for the commercial depression and other disturbing causes in the latter half of year, the increase would probably have been greater. Towards the end of the year a new 300-h.p. dynamo was brought into use. This will prove a great advantage in enabling us to deal with our daylight load without starting the larger machines, and in this way a marked economy will be effected. The 10,000-volt trunk main from Deptford to London, originally fixed to the parapet of the South-Eastern Railway, were removed and laid underground with perfect success during the summer, and without any interference with the continuity of supply. By this important work we are now protected from the accidents from which we suffered so seriously in the past; whilst the annual charges will be considerably decreased, owing to the reduction in the cost of maintenance, and the rental of way-leaves on the railway. The distributing mains have been carried into the parish of Chelsea, and further extensions have been made in the parishes of St. George's, Hanover-square; St. James; St. Martin's; St. George-the-Martyr's; St. Margaret and St. John; St. Saviour's; St. Olave's and Newington; amounting in all to 2¼ miles, bringing the total length of distributing mains laid to 38 miles. All the Company's mains have worked satisfactorily during the year, and the charges for repairs and maintenance have been lessened. A filtering plant, capable of dealing with 100,000 gallons of water per day, has recently been erected at Deptford, by which we are now able to use the river water for the boiler supply, and thus to dispense with a great portion of the supply hitherto derived from the Kent Waterworks Company. This will result in a saving of from £400 to £500 per annum under present conditions. New house transformers, amounting to 2,442 h.p., were purchased last year; of these 1,477 h.p. are now in use on the circuits, leaving in stock 965 h p., which are being put into use as speedily as possible. Owing to the delay of the manufacturers in making delivery, it was not until the last month of the year that this work could be commenced, but from the observations I have taken up to the present time I am able to say that this change will have good economical results. To replace the whole of the old-type transformers now in use, a further 1,045 h.p. of the new type will be required. The generating and distributing plant is in good order, and is working to my entire satisfaction.

P. WALTER D'ALTON, Engineer-in-Chief.

Dr Fleming's Report.—I have read the report of your engineer and agree with it. The replacement of the old form of house transformers by instruments of newer and more economical type has now proceeded to a considerable extent. The result of this exchange has already made itself evident, as we anticipated it would, in a decreased proportion of loss in distribution. There is every reason to believe that when this exchange is completely effected the gain in economy will show itself to the extent indicated in the report of last year. A careful process of testing each transformer for efficiency before it is employed is now adopted. Methods have also been put into operation during the last year for measuring the total daily output from the generating station, which permit the effect of improvements in the distribution plant to be clearly ascertained. A systematic record is thus obtained of the number of units generated as well as sold.

J. A. FLEMING, M.A., D.Sc., F.R.S.

The seventh ordinary general meeting was held on Wednesday at the offices, Adelphi-terrace, W.C., under the presidency of Mr. James Staats Forbes. The secretary (Mr. R. Stewart Bain) read the notice convening the meeting.

The **Chairman**, in moving the adoption of the report and accounts, said that they would see that there was a large margin of ordinary capital and a small amount of preference unissued. With regard to the statement of loan capital, he had drawn attention at the previous meeting to the necessity of raising more capital. Lord Wantage, one of the directors, had advanced £50,000 on the mortgage of the Company's undertaking, and the principal money would be due in three years from the contracting of the loan. Since then partly expansion and partly breakdowns and rebuilding had involved the necessity of extending the loan to £80,000. What was to be done in face of that sum? It was practically expended, and the Company would have to devise means of obtaining a small amount of capital to enable them to carry on for the next two years. The loan became repayable in March next year. With respect to the undertaking as a going concern, the accounts for the year showed this, that although they were not as good as they could have hoped, they were a great deal better than in the corresponding year. In 1892 there was a loss of £4,000, but this year a minute profit was shown. The Company had increased the number of lamps from 46,197 in 1892 to 61,924 in December, 1893, or an increase of 34 per cent. Whilst disturbing causes had affected the Company, they must not blind themselves to the fact that the progression during the past year had shown even the most marked improvement in the remedy of the diseases in the various parts of the system. He thought the undertaking would turn upon how far they could establish a character for a continuous and efficient supply. If things had remained normal, the results would have been correspondingly good in respect to receipts, but the receipts showed an increase of only 6 per cent.; therefore they had 30 per cent. more lamps alight to only 6 per cent. additional income. That was easily explained by the facts that the price per unit had been reduced, and that competition among the different companies had led to the diminution in price. It had fallen from 10d. in 1891 to 8d. in 1892, and to 6d. in 1893. The cost per unit had almost become the selling price, and the effect had been the same all round with the other companies. The latter were happy in the sense of being more developed, and because their capacity of development had cost them a vast deal less than the London Company; the former followed in the wake of the known, and did not rush to the unknown. It seemed, however, that the London Company was on the highway to a better state of things. Summing up, it came to this: increase in lamps 34 per cent., increase in receipts 6 per cent., diminution in expenditure 9 per cent., units distributed 30 per cent. increase, and units sold 20 per cent. increase. The effect upon the lamp was various: 6·15 was the price, as against 6·89 in 1892, and 6·92 in 1891. The public were now purchasing current by meter, and were economical in its use. Thus they got hit both ways. The companies might be driven to charge in their own interests what the law allowed them. The cutting of rates, coupled with diminished consumption, would soon find its level. The average consumption per 8-c.p. lamp in 1891 was 20·61 units, in 1892 21 units, in 1893 17·85, arising from the causes referred to. Concerning the apportionment in these accounts of general charges to capital account, it had been considered advisable while the business was progressing to put some of the general charges to capital account. This year they had placed £4,000—other companies had done so—and he believed the Board of Trade would sanction the matter. The result of all their expenditure was this: they had now got machinery in work for the lighting of 90,000 lamps; they had now 65,000 connected. At present they had sufficient reserve to secure them against danger of breakdown, but they would come to the danger point between 70,000 and 80,000 lamps. They ought to spend £12,000 in providing another dynamo of a capacity of 25,000 lamps. They intended to develop existing fields, and not search for new ones. That could not be done without money. As he had remarked, Lord Wantage had found £80,000 on mortgage, and that had practically been exhausted. The directors had thought it desirable to invite the attendance of a number of shareholders before the general meeting. Some gentlemen came, but he was sorry to say they did not make much advance. Those ordinary and preference holders seemed to think it was so hopeless that it was not worth while making any effort. That would be suicide. Surely the £250,000 of preference and £550,000 of ordinary capital was worth making some effort for. It was not as if they had to raise half a million: they only wanted £25,000, which would carry them on for 12 months. Were they going to chuck up the sponge for that sum? If they did so, what would happen? They were in the hands of a gentleman who had the largest interest in the Company, and he did not think that he was likely to resort to extremes. The increase in the number of lamps had proceeded in a satisfactory ratio, and if they went on at that rate they would soon have 90,000 lamps, and the greater portion of the income of the increased number would be absolute profit. A shareholder had formed the idea that the ruin of the Company had been the enormous loss of current in transmission. Well, that loss, according to Dr. Fleming, was only about 5 per cent. The great drawback had been not in the magnetising of the large transformers, but in the small converters of consumers. They had had to take out transformers which were extremely wasteful and put in extremely economical transformers. They had found that the percentage of current sold as compared with that generated was only 45 per cent. They had only introduced a few of the improved transformers, but that process was proceeding, and the result so far had been that in 1893 the proportion of current sold was 49·46 per cent., and at the present it had reached over 50 per cent. They had just arrived at the stage where light was emerging from darkness, and it would be almost a scandal for the people interested in the undertaking to let it drift for want of a little courage. The actual proportion during the quarter ending December 31 of the current put into the mains at Deptford, and received in London, was as follows: lost in the mains, 3·37 per cent.; station transformers, 3·50 per cent.; house converters, 47·70 per cent.; and lamps, 45·43 per cent. To March 31 the figures were: mains, 4 per cent.; station transformers, 3·50 per cent.; house converters, 38·70 per cent.; lamps, 53·80 per cent. He believed that they had during the past week reached 62 per cent. in the latter case. He referred to the reports of Mr. D'Alton and Dr. Fleming. Adverting again to the mortgage, he stated that £30,000 would be required to carry on the undertaking for the next two years. He then moved the adoption of the report and accounts.

Major C. B. Waller, the deputy chairman, seconded the motion.

Mr. Barham adversely criticised the position of the undertaking, and asked whether any effort had been made to meet the other companies so as to prevent rate cutting.

Mr. Mullins considered that it would be useless to attempt to raise money without giving an inducement to do so.

The **Chairman**, in reply to the discussion, said that negotiations were proceeding with the other companies in regard to the cutting of rates.

The motion for the adoption of the report and accounts was put and carried.

Messrs. J. Pyke and Major Waller were re elected directors, and the auditors were reappointed. A vote of thanks to the chairman closed the proceedings.

BUSINESS NOTES.

Bedminster.—It is intended to light Redcliffe Church by electricity.

Worthing.—The town clerk is making enquiries in regard to electric lighting.

Hampstead—The foundation-stone at the central station is to be laid on the 23rd inst.

Hobart Electric Tramway Company.—For the month of April the receipts were £1,174.

Darlaston.—The Local Board are about to consult an electrical engineer on lighting matters.

Western and Brazilian Telegraph Company.—The receipts for the past week were £2,924.

Great Northern Telegraph Company.—For the month of April the receipts were £20,000

West Coast of America Telegraph Company.—The address of this Company is now 50, Old Broad-street, E.C.

Buxton.—The proposal that the Local Board should light Buxton electrically has, it appears, fallen through.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 6th inst. amounted to £874.

Dover.—The electric light company are laying down mains at the back of East Cliff, where their station is being erected.

Belfast.—The Board of Guardians have appointed a committee to consider the question of lighting either by electricity or gas.

Direct Spanish Telegraph Company.—The receipts for the month of April were £1,742 the same as for the corresponding period.

Shoreditch.—The Shoreditch Vestry have decided to make all arrangements for pushing forward the electric lighting of the district.

Pupil Required.—Messrs. Swinburne and Co., Limited, of Teddington, have a vacancy for one premium pupil for electrochemistry.

West Hartlepool.—The Electric Construction Company have approached the Town Council with a view to lighting the town by electricity.

Reuter's Agency.—The prospectus of Reuter's Agency Advertising Company, Limited with a capital of £100,000 is being circulated.

Northumberland.—The County Council have under consideration the question of lighting the asylum electrically. Mr. W. C. Mountain estimates the cost at £5,350.

Removal.—The offices of the Western and Brazilian Telegraph Company, Limited, and the London Platino-Brazilian Telegraph Company, Limited, have been removed to Blomfield House, London-wall, E.C.

Theatre-Lighting at Birmingham.—The firm of Messrs. Vaughan and Brown, of Kirby-street, London, E.C., have been responsible for the lighting of the Empire Palace Theatre at Birmingham.

Harp Arc Lamp Syndicate, Limited—This Company has been registered, with a capital of £5,000 in £1 shares, to enter into an agreement with W. Trubshawe, and to carry on business as electric lamp manufacturers.

Stock Exchange Quotation.—The Stock Exchange Committee have ordered the £150,000 5 per cent. debentures Nos. 1 to 1,500 of the Telegraph Construction and Maintenance Company, Limited, to be quoted in the official list.

Digitized by Google

Burton-on-Trent.—The Town Council intend to apply to the Local Government Board for permission to borrow money to complete the electric light installation.

Abergavenny.—The Gas Committee of the Improvement Commissioners are considering a report from the engineer on the subject of lighting the town by electricity.

Shoreditch.—The Shoreditch Vestry have decided that the arrangements for carrying out the electric lighting system by the Vestry shall be pushed forward with all possible despatch.

Bootle.—The Town Council have accepted the tender of Messrs. W. and J. Robinson and Co. for the supply and erection of the electric light installation in the Town Hall and other Corporation buildings for the sum of £3,224.

Wakefield.—The West Riding County Council have accepted the tender of Messrs. Armitage and Hodgson, contractors, Leeds, for the erection of a Council-chamber, etc. The whole of the buildings are to be wired for the electric light.

Californian Electric Power and Mining Development Syndicate, Limited.—This Company has been registered with a capital of 30,000 in £1 shares, to acquire and turn to account electric lighting and power works and mining properties in California and elsewhere.

Runcorn.—The Rural Sanitary Authority have received a letter from the Telegraph Manufacturing Company, of Helsby, stating that Mr. Farrington had called and they had agreed regarding the course and style of the drains to be constructed across Mr. Adamson's field.

Tenders for Electric Tramways.—The Minister of Public Works, Cairo, will receive up to July 1 next tenders for the construction and working of tramways in Cairo and neighbourhood. Either electric or animal power may be used. A deposit of £1,000 (Egyptian) will be required.

Western and Brazilian Telegraph Company.—The Board, after placing £5,000 to the reserve fund and £7,073 to the debenture redemption fund, recommend the payment of 7s. 6d. per share, tax free, being a dividend of £2. 10s. per cent. for the 12 months ended December 31.

City and South London Railway.—The receipts of the Company for the week ended May 6 were £886, against £793 for the same period last year, or an increase of £93. The total receipts for the first half-year of 1894 show an increase of £246 compared with those for the corresponding period of 1893.

St. Pancras.—The St. Pancras Guardians have referred to the Finance Committee the question of lighting the workhouse by electricity. The gas bill at present amounts to about £1,300 a year. The Baths Commissioners have been requested by the Vestry to consider the question of lighting the baths by electricity.

Blackpool.—Messrs. Baxendale, of Manchester, have secured the contract for the laying of the electric lighting plant at the North Pier, the whole of which has to be completed within one month. The pillars for the lights will be placed down the centre of the pier, instead of at the sides, as is the case with the gas lamps.

Tenders for Brighton.—The Town Council invite, by the 16th inst., tenders for the supply of motor alternators, transformers, meters, etc. Specifications can be obtained on application to Mr. Francis J. Tillstone, town clerk, Town Hall, Brighton. Tenders are to be addressed to the town clerk. A fee of £1. 1s. will be charged for the specification.

Tenders for Stores.—The Great Eastern Railway Company invite, by the 17th inst., tenders for the supply of stores and materials, including galvanised iron, tin, lead, etc., cotton waste, telegraph materials, leather, indiarubber, etc. Forms of tender may be had on application to the Secretary's Office, Liverpool-street Terminus, E.C.

Accrington.—A committee of the Town Council have again considered the question of electric lighting, and a deputation, consisting of the Mayor, Alderman Moorby, Councillors Eli Higham and Riley, is to visit Halifax, and inspect the form of destructor in use there for generating steam for electric lighting by the burning of the town's refuse.

General Manager Wanted.—The directors of the Salt Lake and Ogden Gas and Electric Light Company, Limited, invite applications for the post of general manager at their works in Salt Lake City, Utah. Applications are to be sent to Mr. J. A. Kelman, secretary, Salt Lake and Ogden Gas and Electric Light Company, 251, Winchester House, Old Broad-street, E.C.

Bath.—The Town Council have received six tenders for the wiring of the Municipal Buildings, ranging from £497 by the Bath Electric Light Company to £245 by Messrs. Wyndham and Waters, of Croydon. The next lowest was £330, and, said Alderman Murch, not only was the £245 by far the lowest tender, but the firm was unquestionably reliable. The tender was accepted.

York.—At a meeting of the City Council there have been adopted the minutes of the Electric Lighting Committee reducing the tenders for consideration at a special meeting to the following: Brush Electrical Engineering Company, Limited; Electric Construction Company, Limited; Messrs. C. A. Parsons and Co.; and Messrs. Siemens Bros. and Co., Limited.

A Penny in the Slot.—"Sensation," care of Messrs. Deacon's, Leadenhall-street, E.C., advertises that he has patented an electric penny-in-the-slot boot-cleaning machine, which cleans both boots simultaneously, while on the feet, in about one minute. He has a full-sized model in working order, and wants a partner, or a syndicate, with £2,500, to develop sufficiently for forming a company.

Mansfield.—A letter from Mr. Hodson has been read at a meeting of the Water Committee of the Town Council as to the laying of telephonic communication from the new works to the manager's office. It was resolved that the sub-committee confer with Mr. Hodson and the borough surveyor as to the best means of having the telephonic poles erected, and that the work be proceeded with at once.

Issue of Fresh Capital.—The directors of the Hastings and St. Leonards-on-Sea Electric Lighting Company announce the issue of additional £10 shares at par. The list will close to-morrow (Saturday). The prospectus states that dividends of 5 and 7½ per cent. were paid in 1890 and 1891 respectively, and also of 5 per cent. in 1892 and 1893. The additional capital is required for extending the present works.

Thetford.—The question of lighting St. Peter's clock has again been considered by the Town Council. The half-year's bill for gas is £8. An estimate for laying on the electric light has been received. The cost would be for fittings, to include four 8-c.p. lamps, £4. 10s.; light, £6 per year; and for 16-c.p. lamps, £8 per year; the hours to be from dusk to 11.30 p.m. The Council decided to put in the electric light.

South Shields.—The site of the station which the Town Council have decided to erect is at Low Foundry, West Holborn. The Council have adopted the scheme prepared by Mr. Joseph A. Jeckell, the borough electrical engineer, the estimated cost being £22,000. Application is to be made to the Local Government Board to borrow this sum, and a deputation has been appointed to visit several stations recently built.

Brush Electrical Engineering Company.—The offices of the superintending engineer's department have been removed from 112, Belvedere-road, Lambeth, to the undermentioned address. All communications should now be addressed to the superintending engineer, Brush Electrical Engineering Company, Limited, 49, Queen Victoria-street, London, E.C. The telegraphic address will for the present remain "Effulgent, London."

Hastings.—The town clerk has been authorised to give undertakings to persons from whom consent has been or may be obtained to the affixing to their premises of wires, etc., in connection with the fire brigade electric bell communication, to remove the wires, etc., upon receiving such notice as the persons giving the consents may stipulate for, and to pay on demand a nominal annual acknowledgment in respect of the privilege.

Electric Lighting of Trains.—The flooring and sides of the brake-vans in which the accumulators are carried on the electrically-lighted trains of the L.B. and S.C. Railway are being coated with anti-sulphuric enamel, so as to prevent damage by the fumes and spray given off from the batteries. This material is also being employed by the Birmingham Central Tramways to prevent possible damage to the cars from storage batteries.

St. Austell.—With respect to the electric lighting scheme, the Board of Trade have officially reported to the House of Commons that the undertakers are Messrs. Veale and Co., Limited; that the area of supply is the district of the St. Austell Local Board; that the order contains provisions for the supply of electrical energy within the area under certain specified conditions. The order also provides for the revocation of the St. Austell electric license of 1885.

The Nottingham Station.—The contract for the erection of the massive cast-iron chimney cap at this station has been entrusted to Mr. W. J. Furse, of Nottingham, who makes a speciality of that kind of work, and has designed a special hoisting arrangement to ensure the safety of the undertaking. The diameter of the cap is 13ft. 6in., height 8ft., and the weight over nine tons. The shaft, from the designs of the borough engineer, will be 160ft. high, octagon in shape, and built from the inside.

Portsmouth.—The Town Council have decided not to effect any insurance at present on the new station, as all the insurance offices asked 5s. per cent., which, for an insurance of £30,000, meant an annual premium of £75. Several applications have been received by the Town Council for the supply of electricity in Russell-street, and the Electric Lighting Committee have asked for powers to carry the mains with transformers through that thoroughfare at a cost of £550. The necessary permission has been given.

Greenock.—A sub-committee of the Town Council has been appointed to consider a better method of lighting the Town Hall. The *Greenock Herald* suggests that the Council would act more wisely were they to go outside gas lighting altogether, and by using a portion of the waste of water which now runs down certain waterfalls to turn a turbine, not only the hall might, at a very small cost, be illuminated by the electric light, but also the various offices throughout the Municipal Buildings—with the exception, possibly, of the gas offices.

Bathgate.—The electric light has been introduced into Bathgate by Mr. Henry S. Kirsopp, draper, who has had his warehouse and dwelling-house fitted up. The machinery consists of a Tangye gas-engine and an Elwell-Parker compound-wound dynamo. On Friday last the light was turned on by Provost Dougal, in the presence of the Town Commissioners and other public officials. The work has been done by Messrs. Hunter and Jack, 101, St. Vincent-street, Glasgow, and this being the first installation in the West Lothians, it has caused considerable interest in the district.

Chiswick.—The Local Board have received a letter from Mr. Hucklebridge applying for a copy of the agreement for the transfer of the provisional order for Chiswick electric lighting. The matter has been referred to the clerk. The clerk reported at a meeting of the Local Board last week that he had received a

Digitized by Google

communication from the Board of Trade with amended regulations as to the supply of electric light in Chiswick, and that he did not regard those alterations as being material. The surveyor stated that the boilers were completed, and that the engines would soon be finished.

Acton.—The Local Board have received a letter from Mr. Medhurst asking for several further alterations to be made in the draft agreement for the lighting of the district by electricity. The Chairman intimated at a meeting of the Board last week that he believed the fact of the matter was that Mr. Medhurst was unable to carry out the proposed contract. There were, he knew, other contractors who would be pleased to take up the work. The letter was referred to the Works Committee, who were empowered to close the negotiations if Mr. Medhurst was not prepared to come to terms without further delay.

Lynton.—At the last meeting of the Local Board, Mr. Benn attended and explained that he was parting with his electric lighting works to a company who were prepared to give a more efficient light by obtaining greater water power. They proposed erecting a storage tank on Summer House-hill capable of giving a two days' extra supply. He asked the Board whether they would be willing to resume the lighting contract with the company for 14 years. It was resolved that on the Board being satisfied that the additional works are satisfactory, and the lighting efficient, the Board would extend the lease as requested.

New Installations in Leeds.—Mr. T. Harding Churton, of Leeds, has secured the contract for the lighting of the Great Synagogue in Belgrave-street, Leeds, by some 77 incandescent lamps of various candle-powers. Among some of the installations recently carried out by Mr. Churton in Leeds may be mentioned the Leeds Law Institute, Philosophical Hall, the Leeds Library, Messrs. Roper and Sons' mill (with accumulators), besides a number of private houses and business premises. The lighting of the medical schools, which are to be opened shortly by the Duke and Duchess of York, is also in Mr. Churton's hands.

St. Luke's.—The County of London and Brush Provincial Electric Lighting Company, Limited, have served notices upon the St. Luke's Vestry of their intention to commence laying mains in the parish. The Parliamentary Committee having considered the matter have recommended that opinion should be taken as to whether the order obtained by the company was effective in view of the fact that its terms had not been observed by the company, and that the Vestry should intimate to the company that it was not prepared to consent to the execution of such works. This has, however, been sent to a special committee, who will thoroughly investigate the whole matter.

Tenders for Southwark.—The Commissioners for Public Baths and Wash-houses for the Parish of St. Saviour, Southwark, invite specifications and tenders for supplying and fixing an engine and dynamo at the baths, Lavington-street, S.E., capable of producing current for 360 16 c.p. lamps, with all necessary exhaust and steam pipes and connections. Tenders are also desired for wiring the above building and providing storage batteries in accordance with the specification prepared by Mr. F. J. Smith, F.R.I.B.A., 17B, Great George-street, Westminster, from whom all information can be obtained, and at whose office the contract can be seen. Tenders are to be delivered by the 16th inst.

Electric Lighting at Manchester.—The Electric Lighting Committee of the Corporation of Manchester have ordered from Messrs. Mather and Platt, Limited, two Edison-Hopkinson dynamos, each of 400 h.p. The machines are to be similar to the two machines already supplied by this firm, having an output of 410 volts and 590 amperes at a speed of 400 revolutions per minute, and are intended to work upon the feeders of the five-wire system. The committee have had so many applications for the electric light that their present plant is fully loaded, and an extension is necessary before next season. These dynamos are to be worked by Galloway engines, similar to those already supplied by this firm.

Bury.—The County Council have adopted the minutes of a meeting of the Electric Lighting Committee, held on May 3, when the borough surveyor submitted drawings, specifications, and estimates for the erection of buildings, engines, boilers, dynamos, and all necessary plant for the supply of electric light to the borough. It was resolved that the plans, specifications (subject to confirmation by Dr. Hopkinson) be approved, and that tenders be obtained for carrying on the works; that the borough engineer dispose of the old material now on the site required for the electric lighting station, and that application be made to the Local Government Board for sanction to borrow £25,000 for electric lighting purposes.

Bradford.—The Town Council on Tuesday decided, on the recommendation of the Gas and Electricity Committee, as stated in our last issue, to issue a circular to residents of the districts of Frizinghall, Manningham, and Heaton, which are not within the area of the gas supply of the Corporation, to ascertain their wishes with regard to supplying such districts with electricity. The electrical engineer in the meantime was authorised to prepare an estimate of cost of suggested works. It was decided to issue a circular to residents in Great Horton-road and Otley-road, and in places in the neighbourhood of those thoroughfares, to ascertain to what extent they would be prepared to take a supply of electricity in the event of the Corporation extending the electric cables to the said districts.

Lighting in Poplar.—The Poplar District Board have discussed the report on electric lighting presented to them by Mr. Preece, which was referred to in a previous issue. Mr. Preece, it will be remembered, strongly recommended the Board to undertake the lighting of the district itself, as after the first year a profit would be made on the undertaking, for which a capital of £30,000 would be sufficient to commence with. He also added that his figures could be relied upon as accurate, and stated that the Board need have no fear of failure in taking the new departure, they having already obtained the necessary parliamentary powers. At a meeting of the Board last week, Mr. Bussey said that he thought it would be a good opportunity to utilise the dust for the purpose of generating the electricity. The Board, however, decided to send Mr. Preece's report to the Works Committee.

Lighting at Hull.—At a meeting last week of the Hull Town Council the most important matter was a discussion on a report presented by the Electric Light Committee, in which it was proposed to reduce the charge for electricity from 7d. per unit to 6½d. Dr. Holden, the chairman of the committee, stated that they spent £1,631 to produce a return of £2,510. and after paying all costs of working, there was a balance of £888, from which £750 went to pay interest, leaving a profit of £138. In the first quarter there were 42 users, in the second 50, in the third 64, and in the fourth 148. They commenced by supplying 3,790 8-c.p. lamps, and ended the financial year with supplying about 9,400. During the 11½ months 74,600 units were used. They expected increased consumption during the coming year, and that they would be able to make a considerable reduction. The report was adopted.

Glasgow.—At a meeting of the Town Council last week, Baillie Alexander asked what progress had been made in regard to the establishment of telephones. Mr. Starke said the matter was before Parliament a few days ago, and Mr. Morley stated that the agreement between the Post Office and the National Telephone Company was still under consideration. That agreement, it was understood, practically gave the monopoly of ground areas in municipalities to the telephone company, the Government taking the trunk wires. Mr. Morley's attention had been drawn to this provision. He was considering the subject, and Mr. Starke hoped that when it was laid before Parliament it would be on different terms from those originally proposed. The refusal to lay the agreement before Parliament till it had been signed had been departed from, and when it was laid before Parliament it would be proposed that a select committee be appointed to consider the whole question.

Sheffield.—The Improvement Committee have passed the following resolution: "That the tender of the Sheffield Electric Light and Power Company, Limited, for the 'wiring' of the Town Hall, for the sum of £750, be accepted, the Corporation to take the current from that company's mains for 12 months from the opening of the complete building, but on condition that the company maintain the installation in good working order during that period, and so leave it at the expiration thereof, and the Corporation to be at liberty, after such period, at any time to discontinue taking the current from the company's mains if the Corporation think fit so to do." The electric lighting company have applied to the Highway Committee for permission to lay cables in Leopold-street, Bow-street, and West-street. It was reported that the footpaths on each side of Bow-street and West-street were to be disturbed for their whole length, and most of the flagging had been laid during the last two or three years, some of it during the last few weeks. The application has been granted.

Gas and Electricity.—The eighteenth annual meeting of the shareholders of the Liverpool Gas Fitting Company, Limited, was held at the Company's offices, Liverpool, on Wednesday, Mr. J. Barkeley Smith, chairman of the Company, presiding. Mr. J. N. Stolterfoht, in moving a vote of thanks to the directors, said that he was glad to see that the Company laid themselves out for supplying fittings for electricity as well as for gas. The newer form of illumination was gaining the upper hand, and they were well advised in keeping abreast of all the possible requirements of the future. The Chairman, in reply, explained that some years ago, when electricity was coming to the front, they altered their articles of association to enable them to supply fittings for the electric light. Had they not done so they would have lost a good deal of business which had lately come to them. The attention of the manager had been specially called to that branch of the business. They were constantly getting orders for it, and that was one reason why they were able to maintain their dividend.

Lighting of Guildford.—The Board of Trade have issued a provisional order under the Electric Lighting Acts, 1882 and 1888, with a view to the same being included in a Confirmation Bill about to be introduced into Parliament, authorising the Holloway Electricity Supply Company to supply electrical energy for public and private purposes in Guildford. The following clause has been ordered by the Board of Trade to be included in the provisional order: "Purchase by the Local Authority.—The option of purchasing the undertaking under the provisions of Section 2 of the Electric Lighting Act of 1888 may be exercised by the local authority within six months after the expiration of 35 years after the commencement of this order, but if the said option is not exercised under the foregoing provision, the said section of the Electric Lighting Act, 1888, shall apply as if this section had not been included in this order." The company will, therefore, have a monopoly for exactly a quarter of a century beyond the period to which the majority of the members of the Corporation originally agreed to consent. Mr. Sidney Sharp is the engineer to the company.

Western and Brazilian Telegraph Company.—The total earnings amount to £80,338. 18s. 3d., as against £86,954. 11s. 2d., showing a decrease of £6,615. 12s. 11d. compared with the half-year to December 31, 1892. The working expenses amount to £35,592. 8s. 10d., as against £37,165. 11s. 5d., a decrease of

Digitized by Google

£1,573. 2s. 7d. Including the amount brought forward from June 30, 1893 (£7,679. 4s. 7d.), and the dividend received upon the shares held in the Platino Company, the balance to the credit of the revenue account is £61,659. 9s., from which has been deducted £12,027 for debenture interest, and £7,073 for the debenture redemption fund, leaving £42,559. 9s., of which £5,000 has been placed to the reserve fund. The directors now recommend the payment of a dividend of 7s. 6d. per share, free of income tax, on the ordinary shares, being a dividend of £2. 10s. per cent. for the year, leaving a balance of £1,045. 6s. 6d. to be carried forward. In the case of shares which have been divided into preferred and deferred, the 7s. 6d. per share now recommended will be payable to the preferred shareholders, making up the full dividend of £5 per cent. on the preferred shares for the year 1893.

Lighting of the Agricultural Hall.—The Theatre and Music Halls Committee of the London County Council reported on Tuesday that they had received two plans from Mr. R. Venner showing the formation of engine and electric light rooms in the vaults under King Edward's Hall at the Royal Agricultural Hall. The committee recommended that the plans be approved on the following conditions: (1) that a second iron door be provided at the foot of the staircase leading to such vaults; (2) that the vaults be entirely cut off by a fireproof construction from the surrounding cellars; (3) that an iron ladder with handrails on both sides be provided in order to form a second means of exit into Berners-street from the engine-room, through the present bulkhead; and (4) that the engine and battery rooms in the basements be ventilated to the satisfaction of the engineer of the Council. The committee also reported that they had received four plans from Messrs. Crompton and Co. showing the arrangement of leads, method of suspending cable, and hoisting gear, and the electric lighting plant at these premises. They recommended that the plans be approved on condition that any modifications that may be required by the engineer of the Council be adopted by Messrs. Crompton and Co.

Lighting in Battersea.—In the course of a communication to an evening paper, Mr. G. W. Halliday, of 3, Meath-street, Battersea, says: "About five years ago a proposal was made, and the Works Committee of the Battersea Vestry considered the lighting of that parish with electricity. The Battersea people enjoy in the very centre of the parish the presence of a dust destructor. Some 70 loads of dust are consumed at the destructor per day, and some members of the Vestry have thought it would be well if the consumption of the dust could be used for heating purposes. Mr. Simon wanted it to make the water of the baths tepid, but they heeded him not. I understand, however, that two of the oldest and most practical members of the Vestry have been deputed to visit works and report soon to the Electric Lighting Committee whether or not the consumption of the dust can be utilised for that purpose. Battersea has now 2,000 street lamps, and they cost about £6,000 per annum; and some think that all the energy necessary could be got out of the refuse. Even though all the private lighting had to be supplied by coal as the fuel, it is very doubtful if it would be possible for the Vestry to charge more than 3d. per unit, and the result would be a much better atmosphere than there is now."

Electric Lighting at Bath.—A novelties exhibition has been held in Brock-street. The electrical department, through the enterprise of the electric lighting company and Mr. G. F. Metzger, was fitted up with elaborate completeness. The current was supplied by the company, and Mr. Mactavish, of New Bond-street, who was acting in conjunction with them, exhibited all kinds of novel appliances for the turning of electricity to practical use. The cooking and heating apparatus were kindly lent by Messrs. Crompton and Co., Limited, and alternating motors by the Electrical Company of Oerlikon; whilst the former also lent a search-light. The *Bath Herald* of Friday last says: "The electric lighting company and the Bath Corporation do not work together so amicably as might be wished. The installation of the electric light into the city came certainly as a boon, but the company, as a kind of acknowledgment for their enterprise, have been in receipt of more kicks than ha'pence. The latest outcry in the city is that respecting the late hour at which the lights are switched on, but in justice to those at the works I would explain that the company are acting strictly in accordance with the time-table drawn up by the Lighting Committee, and if there are grievances the Lighting Committee should bear them and not the company. The penalty system adopted has already been referred to in this column. Last quarter the company for 71 failures paid in fines no less than £17. 15s., and yet the gas company got off scot free."

South Staffordshire Tramways.—In the Chancery Division, on Friday, the petition referred to in our last issue for the winding up of the South Staffordshire Tramways Company again came before Mr. Justice Williams. Mr. Bramwell Davis, for the petitioners, read an affidavit to the effect that shareholders representing £70,000 supported the petition, while shareholders to the amount of over £38,000 opposed it. Mr. Buckley, Q.C., opposing the petition for the Company, said the petition had alleged a number of matters for the purpose of establishing a case of fraud. These charges had failed, and no case was made out. He, therefore, asked that the petition should be dismissed with costs. Mr. Warmington, Q.C., for the debenture-holders, said their only chance of getting their money back was to keep the company as a going concern. It was proposed to extend the area of tram lines, and, instead of steam traction, to use electric power and cable. Mr. Justice Williams expressed the opinion that it was not desirable the business should continue to be managed by the receiver for the debenture-holders under circumstances which gave the shareholders no voice at all. Mr. Bramwell Davis said the shareholders wanted to remove Mr. Wain from the chairmanship of the company, and to have an efficient voice in the management. It was ultimately arranged that the petition should be adjourned in order that a meeting of the shareholders should be held in London. The shareholders were to say whether they were in favour of a winding-up order or not.

Accepted Tenders.—The following tenders were received for alterations to sub-station in Pavilion-road, for the Chelsea Electricity Supply Company, Limited:

T. D. Leng, Deptford	£474
W. Stevens and Co., Chelsea	438
J. Douglas, Chelsea	391

The tender of the latter has been accepted. For alterations to sub-station in Manor-street, for the Chelsea Company, the following tendered:

T. D. Leng	£638	0	0
W. Stevens and Co.	613	0	0
J. Douglas	515	10	0

The tender of Messrs. Baxendale and Co., of Manchester, has been accepted for the construction and maintenance for a period of five years of a telephone between the asylum and Glanywern Hall, a distance of about three miles, for the Visitors of North Wales Counties Lunatic Asylum. The following tenders were received by the Brighton Town Council for the supply and erection of Willans engines, continuous-current dynamos, pipe-work, spare armatures, etc.:

Crompton and Co., London	£5,550	0	0
Siemens Bros. and Co., Westminster	5,940	0	0
India Rubber, etc., Company, Silvertown	6.046	0	0
Johnson and Phillips, London	6 095	10	0
Electric Construction Company, Wolverhampton	6,257	0	0
Easton, Anderson, and Goolden, Limited, London	6,503	0	0

The tender of Messrs. Crompton and Co. has been accepted.

Whitehaven.—At a meeting of the Whitehaven Town and Harbour Trust, Mr. J. G. Dees, the chairman, in connection with the estimates for the year, mentioned that the cost of public lighting this year had been considerably more than was estimated, and he had explained in part the reason of that—that there was one quarter's gas account, £256. 6s. 1d. The actual expenditure for lighting during the 12 months had been as follows: For the 12 months all expenses against the electric lighting station, repairs of lamps, etc., including the bills paid for gas during the period of the year the town was lighted by gas, and also the harbour, £949. 6s. 3d.; amount paid for sinking fund and interest, £130. 15s. 9d.; or a total of £1,080. 2s. The revenue collected was £207. 13s. 3d; leaving the net cost of public lighting for the year ending March 25, €872. 8s. 9d., or £11. 17s. 2d. less than the preceding year, when the town was lighted by gas, the cost of gas having been £884. 5s. 11d., in a year when the cost was considerably less than before owing to strictest economy exercised in lighting. So he thought they might congratulate themselves on the first year's working of the electric lighting. With regard to the next year's electric lighting, it would come to something rather more. The estimated expenditure of the electric lighting station was £930. That is the amount of expenditure at the electric lighting station chargeable to electric light: there is a portion of it charged, of course, to sewerage, which is something considerably less than the cost of the sewerage station used to be. The estimated revenue from electric lighting is £1,063 15s., which is made up of the amount payable by the harbour under contract £220, and the sale of current estimated at £843. He thought this estimate was a very fair one. Last year, the amount of current sold to consumers during seven months was 26,000 units. The surveyor's estimate of the requirements of the 12 months was 45,000 units; and he (the chairman) thought that was very moderate, inasmuch as during those seven months it was only towards the end of the seven months that many of their big customers were obtained, and very few of their customers ran the whole of the seven months.

PROVISIONAL PATENTS, 1894.

APRIL 30.

8500. **Electrical connector for making insulated joints under water or clay between cable or other insulated wires.** Henry R. Vereker, Summerville, Westport, County Mayo.

8512. **Improvements in and connected with insulators for overhead electrical conductors.** Arthur Wiglesworth, 10, St. George's-crescent, Liverpool.

8525. **A method of overcoming induction on telephone and transmitting lines.** Addison Goodyear Waterhouse, 33, Old Broad-street, London.

8534. **Improvements in electrically-propelled vehicles.** Walter Charles Bersey, 53, Chancery-lane, London.

8539. **Improved telephone and exchange system.** Emile Andreoli, 18, Somerleyton-road, Brixton, London. (Pierre Emile Raverot and George Albert Hess, France.)

8548. **Improvements in the construction of spring reels for roses for ceilings or wall connections and other electrical fittings.** Killingworth William Hedges, 8, Quality-court, Chancery-lane, London.

8556. **An improved electrically-operated door-chain or the like.** Eduard Stoessel, 6, Lord-street, Liverpool.

Digitized by Google

8552. **Improved commutator brush.** Rudolf Kersberg, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 1.

8566. **Improvements in alternating and multiphase current dynamos.** Thomas Parker, Manor House, Tettenhall, Wolverhampton.

8567. **Improvements in brushes and brush-holders for electric generators and motors.** William Harding Scott, Gothic Works, King-street, Norwich.

8585. **Improvements in electric conductors for underground conduits.** Daniel Ellis Conner, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

8587. **Improvements in and relating to electric railways.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (William Burridge Purvis and Meylert Melville Armstrong, United States.) (Complete specification.)

8599. **Improvements in electric arc lamps or lighting apparatus.** Joseph Barclay McKeown, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

8607. **Improvements in or appertaining to electrical exchanges.** William Phillips Thompson, 6, Lord-street, Liverpool. (Alexander E. Keith, United States.) (Complete specification.)

8613. **Improvements in or appertaining to automatic electrical exchanges.** William Phillips Thompson, 6, Lord-street, Liverpool. (The Strowger Automatic Telephone Exchange, United States.) (Complete specification.)

8617. **An electric alarm bag.** Thomas Nickalls White, 45, Fitzroy-street, Fitzroy-square, London.

8634. **Improvements in the means for controlling electric lamp circuits from a distance.** John Corry Fell, 1, Queen Victoria-street, London. (R. H. Postlethwaite, New Zealand.)

8638. **Improvements in alternating-current, simple or polyphase, dynamo-electric machines.** Sydney Pitt, 24, Southampton-buildings, Chancery-lane, London. (André, Blondel, and Sautter, Harlé et Cie., France.) (Complete specification.)

MAY 2.

8654. **Improvements in apparatus used as brackets or chandeliers for electric light.** Robert Neville Grenville and Stephen Harding Terry, 17, Victoria-street, London.

8730. **Improvements in and connected with supports for electrical batteries used on vehicles and the like.** Thomas Froggatt, 1, Queen Victoria-street, London.

8731. **Improvements in electric batteries.** Thomas Froggatt, 1, Queen Victoria-street, London.

8733. **Improved electrical fire and burglar alarm.** Henry Dawson, 45, Hatton-garden, London.

MAY 3.

8761. **Improvements in and connected with electric fire alarms.** Andrew Archibald and George Tarry, 154, St. Vincent-street, Glasgow.

8773. **An automatic electric fire alarm time call.** Frederick Hungate Dennis, 20, High-street, Chelmsford.

8794. **New or improved electrical appliances enabling trains in motion to have constant and direct telegraphic communication with the stations or other trains on the same line.** Pierre Emile Marie Bastion, 77, Colmore-row, Birmingham.

8795. **An improved holder or support for the receivers of telephones.** Andrew Connel, 8, Quality-court, Chancery-lane, London.

8807. **New or improved means for protecting magnetic needles from local attraction.** John Sacheverell Gisborne, 19, Southampton-buildings, Chancery-lane, London.

8808. **Improvements in electric batteries.** Robert M'Lauchlan M'Donald and Alexander M'Donald, 70, Wellington-street, Glasgow.

8812. **Electrical jacquard apparatus for looms.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

8813. **Improvements in electric conductors.** Siemens Bros. and Co., Limited, and Wilhelm Dieselhorst, 28, Southampton-buildings, Chancery-lane, London.

8815. **Improvements in electrolytic cells.** Ludwig Mond and Robert Ludwig Mond, 323, High Holborn, London.

8823. **Improvements relating to the transmission of signals through telegraph lines and cables.** Joseph Arthur Lovel Dearlove, 124, Chancery-lane, London.

8825. **Improved means for conducting electricity through tablecloths, carpets, and the like, to electric lamps and other electrical devices.** The Electrical Installation Company, Limited, and Edmund Lyons O'Brien, 55, Chancery-lane, London.

8838. **Improvements in fuses or cut-outs for electric lines.** Jacob Pillischer, 226, High Holborn, London.

MAY 4.

8895. **Improvements in or connected with secondary or electric storage batteries.** Frank King, 47, Lincoln's-inn-fields, London.

8896. **Electrical apparatus for preventing collisions and other accidents on railways.** Alfred Joseph, 53, Chancery-lane, London.

8917. **Improvements in or in connection with apparatus for the electro-deposition of metals.** Hans Alexander, 34, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 5.

8924. **Self-contained electrical generating apparatus and driving mechanism.** Charles Langstone, Benjamin Young, and James Alfred Ewins, 8, Coleshill-street, Birmingham.

8972. **Improvements in or relating to secondary batteries.** Frederick Griffin, 46, Lincoln's-inn-fields, London.

8976. **Improvements in submarine telegraph cables.** William Sharpey Seaton, 124, Chancery-lane, London.

NOTES.

Rugby.—A proposal is on foot to establish a telephone exchange.

Castrop.—The electric light is shortly to be installed in this town.

Heilmann Locomotive.—It appears that this locomotive is now making daily trips.

Tetschen-Bodenbach.—The Municipality intend to erect a central electric light station.

Ayr.—The Ayr Corporation have resolved to light the town by electricity, at a cost of £15,000.

Frankfort-on-the-Maine.—The electric light is to be installed in the Rothschild Free Library.

Saint-Nazaire.—M. Ch. Milde has applied for permission to establish an electric supply station.

Hamburg.—Large extensions are being made in the main conductors of the municipal electricity works.

Braila.—Tenders will be opened this month for the lighting by gas and electricity of this Roumanian town.

Rochester.—The question of the overhead wires being removed is under the consideration of the Town Council.

Arts and Crafts Society.—Lord Mayo has issued the prospectus of a scheme for forming an Arts and Crafts Society for Ireland.

West Ham.—The West Ham Town Council have decided to allow the electric lighting scheme to go into abeyance for the present.

Nachod.—A local manufacturer proposes to erect a central electricity station for the lighting of the streets and private houses and shops.

Obituary.—The death has just occurred of Mr. Arthur Edward Robinson, head chemist at the Electric Construction Company's Works, Bushbury.

Bordeaux Tramways.—A new company proposes to convert the suburban tramway lines into electric lines, similarly to the Bordeaux-Vigeau route.

A Bull.—"I mean to say," remarked Mr. Hammond at the Institution meeting last week, "that if everybody had a copy of the paper nobody would have to read it."

The Clermont-Ferrand Tramway. — The last year's operations of the company operating this line and also a tramway in Marseilles, allow of a dividend of 4·8 per cent.

Durham.—Mr. H. F. Tulloch, Local Government Board inspector, has held an enquiry into the application of the Corporation to borrow £20,000 for electric lighting purposes.

The Institution.—The paper by Mr. R. E. Crompton on the "Cost of Electrical Energy" will be further discussed at a meeting of the Institution on Thursday next, the 24th inst.

Colwyn Bay.—The Local Board have addressed a memorial to the Postmaster-General, requesting that the existing telephones at Colwyn Bay may be connected with the trunk line.

Traction at Dublin.—The Kingstown Commissioners are desirous of learning from the Dublin Southern District Tramways Company when it is probable that the new electric lines will be laid.

Congratulations.—Sir David Salomons, who presided over the two last meetings of the Institution, is to be congratulated on the business-like manner in which he conducted the proceedings.

London Chamber of Commerce.—The twelfth annual general meeting of the members of the Chamber will be held at the offices, Botolph House, Eastcheap, on Monday next, at 2.30 p.m.

Ruhla.—The first electric lighting plant in Ruhla has been installed at the metal-works of Herr Ferdinand Erk. Several other installations in the neighbourhood will now be supplied with current from the same plant.

What About Electricity?—A discussion has taken place in the Harwich Town Council on the respective merits of gas and oil lighting of the streets. The members do not seem to have heard of the electric light.

The Breslau Electric Tramway.—The first annual report of the company working the electric tramway states that a dividend of 4·7 per cent. will be paid after having provided for depreciation, interest on capital, and reserve.

Liebertwolkwitz.—The Municipality of Liebertwolkwitz, near Leipzig, have decided to adopt the electric light, and preparations will shortly be commenced. The lighting of the market place and the chief streets will be undertaken first.

Schonlinde.—In response to circulars asking who would take electric current if a central station were erected, promises have been obtained which show that there would be a regular demand for current for 1,100 incandescent lamps.

American Institute of Electrical Engineers.—The tenth anniversary of this institute is being held this week in Philadelphia. Among the papers down for reading is one by Dr. Louis Bell on "Some Facts about Polyphase Motors," whilst one by Mr. Wurts will deal with "Lightning Arresters."

Zwickau.—A short time ago a successful experimental run was made on the electric tramway, which has been carried out by Messrs. Schuckert and Co., of Nuremburg. Overhead conductors are employed, which are carried on ornamental posts.

Hard Lines Mixed.—"It seems hard lines," said Mr. Burnett before the Institution last week, in reference to the purchase of fuel by central-station engineers, "to sell light and heat in B.T.U. and have to buy their own materials mixed."

New York.—The overhead trolley system of electric traction has now made its appearance in New York—a line on this method having just been completed on One-hundred and-thirty-fifth street. The regular service of the cars is about to commence.

Wolverhampton.—On Monday next, at 12.30 p.m., the foundation stone of the municipal electricity works in Commercial-road, Wolverhampton, will be laid, and invitations to be present have been issued by the Mayor (Alderman C. T. Mander).

Gas-Engines.—The Saint-Quentin Gas Company is laying down plant for the supply of the electric light in certain parts of the town. Direct-current dynamos have been adopted in conjunction with gas-engines, and the distribution will be on the three-wire system.

Steinau-on-the-Oder.—The Babolz Engineering Works are to be lighted electrically, and it is proposed to make the installation large enough to light the whole town. The Municipality have agreed to take a supply for 342 incandescent lamps and nine arc lamps.

Haardt.—Good progress is being made in the erection of the central station near Haardt and Neustadt, which is being erected on their own account by Messrs. Schuckert

Digitized by Google

and Co., Nuremburg, for the lighting of Haardt, Gimmeldingen, Mussbach, and neighbouring districts.

Romanshorn.—The Municipality have decided to erect a central electric light station in connection with the pumping plant of the waterworks for lighting the railway station and the village. Romanshorn will be the first village in Thurgau, Switzerland, to adopt the electric light.

How to get a Day Load.—The directors of the Westminster Electric Supply Corporation, Limited, have decided to reduce, after Midsummer, the price of electrical energy for motive power, cooking, and heating purposes to 4d. per unit, where the supply is taken through a separate meter.

Cannstadt.—At the new technical college an electric installation has been carried out by the Esslingen Works in the art teaching rooms. The lights are so arranged as to be readily adjustable, and in the model-room the lights are so fixed that the shadows fall the same as they would from sunlight in the open air.

Telephony in Germany.—The telephone network from Berlin, *via* Posen, Gnesen, Bromberg, Danzig, and Elbing to Königsberg has not been available at Königsberg owing to the local authorities having raised objections to the installation of the conductors in the streets. The difficulty has, however, now been removed.

Bristol Electric Time Check.—A catalogue referring to the Bristol electric time check has reached us from Messrs. King, Mendham, and Co., of Bristol, who are the sole licensees. The advantages of this apparatus for checking time in factories and other large establishments where workpeople are employed are now well known.

Monmouth. — The Bill introduced by the Board of Trade to confirm the provisional order empowering the Monmouth Corporation to produce electricity and to lay mains for the supply of current has passed the Examiner upon Standing Orders in the House of Commons, and has been ordered to be reported for second reading.

Gollnitz.—A central electric light station is being erected at Göllnitz (a Hungarian mining town) which will supply 800 incandescent lamps. A separate dynamo of 30 h.p. is to be put up to furnish current to motors for industrial purposes. The work is being carried out by Messrs. Egger and Co., of Vienna and Budapest.

Posen.—The number of electric light installations in this province is rapidly increasing. Sugar refineries at Tuczno, Zduny, Kruschwitz, etc., have been lately thus lighted, and so has the provincial lunatic asylum at Dziekanka, near Gnesen. The chief stations of the Posen-Thorn-Bromberg Railway are also to be lighted electrically.

New French Company.—The Société Générale Internationale d'Eclairage par le Gaz et l'Electricité has been constituted in Paris, with temporary offices at 17, Rue Saint Marc, for the supply of gas and electricity. It is proposed to establish agencies in French and foreign towns, notably at Brussels, Bucharest, Vienna, and Budapest.

Personal.—Mr. E. R. Dolby, C.E., of 8, Princes-street, Westminster, S.W., has been appointed consulting engineer to Messrs. C. H. Glover and Co., Hatcham Saw Mills, for electric power transmission plant and electric crane; to the London Missionary Society; and to a colliery in Derbyshire for lighting, transmission of power, and pumping by electricity.

The Use of Gas-Engines for Electric Light.—Mr. F. H. Mason, the United States Consul-General in Germany, states that since the Frankfort Electrical Exhibition of 1891 the use of gas motors has very largely increased through the cheapening of gas, and the rapid extension of electric lighting and other applications of electricity.

Wreschen.—The electric lighting installation of the local sugar refinery is nearing completion. The residents of the town have now formed a committee for the erection of a central station, which is to be carried out by the General Electricity Company, of Breslau. It will have a capacity for 500 incandescent lamps and 20 arc lamps (for street-lighting).

The Upper Spree.—The Electric Lighting Company of the Upper Spree have informed the authorities of the surrounding districts that their plans have been approved of, and that they are about to commence the erection of their station. The Town Council of Rummelsburg have already decided to enter into negotiations with the company for the lighting of the town.

The Hamburg Tramways.—In a previous issue reference was made to the opening of the electric tramway in this town, and we now learn that the Hamburg Tramways Company has applied to the Senate for permission to use electric traction on all its lines, and that the permission has been granted. The contemplated conversion of the system is to be completed within three years.

Ship-Lighting.—The twin-screw steamer "Duke of York," which has just been completed by Messrs. William Denny and Bros., of Dumbarton, has just made a trial trip in the Firth of Clyde. The electric lighting plant consists of a Crompton dynamo driven by a Browett-Lindley engine. The dynamo is capable of supplying current for 250 incandescent lamps and also for the search-light.

Folkestone.—A special meeting of the Corporation has been held to consider petitions for and against the introduction by the Town Council of the electric light. The resolution passed at the meeting of April 6, approving of a scheme for the installation of the electric light at a cost of £35,000 was revoked, this motion being carried by nine votes against six after two hours' stormy discussion.

Union of German Electrical Engineers.—The council of the Verband der Elektrotechniker Deutschlands, whose address is at Schiffbauerdamm 22, Berlin, N.W., have issued the preliminary programme of the second annual meeting of the union to be held, as stated in previous issues, at Leipzig in June. The proceedings, which will commence by a reception of members on the evening of June 7, will continue for several days.

The Halle Tramways.—It appears that the working of the electric tramway in Halle has adversely affected the horse lines. The company operating the latter proposed some time ago to acquire the electric tramway, but the Municipality placed in the way obstacles which have until now prevented the transfer of the line from the General Electricity Company. It is not known whether negotiations will be resumed.

Havre.—The Havre Chamber of Commerce has offered to advance the State a sum of 92,000f., or, say, about £3,680, for the establishment of a third telephonic connection with Paris, on the condition that the line is reserved exclusively for communications between the two towns until the reimbursement of the sum advanced. In case this stipulation be not agreed to, the Chamber reduces its offer to one half of the sum.

Budapest.—The works of the Budapest General Electricity Company, which compete with those of Messrs. Ganz and Co., in Budapest, are making good headway. They were erected nine months ago, and were projected for 12,000 lamps, while now 16,760 lamps are connected, and

Digitized by Google

application has been made for 36,860 more. The works were erected by Messrs. Schuckert and Co. The local authorities have approved of the scheme for an underground electric railway.

Central Stations in the United States.—Mr. E. A. Armstrong, in his presidential address before the National Electric Light Association, said that, according to the most trustworthy information available, there were now in the United States upwards of 2,300 electricity supply undertakings, representing an invested capital of at least £40,000,000, and that it was estimated that an equal amount was invested in the manufacture of electrical machinery and supplies.

Walker.—A Mr. Walker, Congressman for Massachusetts, has got a nice vocabulary for electrical enterprises. The owners of electric tramways on the trolley system he describes as being "a cruel, heartless, remorseless combination of interests that has no regard for human life or the comfort of citizens," while leading electric manufacturing firms are depicted as "these great dominant unprincipled combines," who have gone in for the conduit system of traction "with the malignity of the infernal regions."

Electricity in Mining.—The Royal mines at Aranyidka, near Kaschau, Hungary, are receiving an interesting electrical installation. At the primary station there is to be a dynamo of about 30 h.p., giving current at 500 volts. This dynamo is driven by a turbine. The secondary station is about a mile distant, and here an electromotor drives the hauling machinery. In order to avoid irregularities in the running of the turbine, it will be provided with an electrical regulator, made by Messrs. Egger and Co., of Vienna and Budapest.

Lifting a Cable.—The cable steamship "Menia," Captain Trolt, belonging to the Anglo-American Telegraph Company, London, has started from Queenstown for the North Atlantic. One of the Anglo-American cables has been found defective in mid-Atlantic, the defective portion lying at a depth of 2,500 fathoms. On lifting the cable it will have to be overhauled, and all the defective parts cut out and replaced by new cables. The "Menia" has aboard 500 miles of new cable, 200 miles of which, or perhaps more, will have, it is calculated, to be used.

To Whom is the Credit Due?—Mr. Nelson W. Perry, an American electrician, in discussing the question of the measurement of electric current, mentions that of the greatest desiderata in many electrical measuring instruments is a material whose electrical resistance shall not vary with the temperature. For a long time German silver was more used than any other known alloy, but Mr. Perry says that it remained for an American, Mr. Edward Weston, to invent an alloy having a zero temperature coefficient. Mr. Perry adds that "the credit for this has been usurped by foreigners, but the honour is due to America."

Aix-la-Chapelle.—The supply of current from central electric lighting stations for tramway purposes is of much importance to those running the stations. In Hamburg the consumption on the tramways already amounts to one-fourth of the total output. It has now been decided to adopt electric traction on the Aix-la-Chapelle tramway, and to take current from the electric lighting station, which was carried out by Messrs. Schuckert and Co. The overhead trolley system is to be employed. The length of the line which is to be thus operated at first is about 14½ miles, which will subsequently be increased to 18 miles. Of 35 cars, 19 will be supplied with 15-h.p. motors, so that they can haul trailers. The rest will have 10-h.p. motors.

Electric Supply at Vevey.—Some interesting particulars and figures are to be obtained from last year's report of the operations carried on by the electrical company of Vevey, Montreux, who supply energy, it will be remembered, for working a tramway and a number of lamps, both arc and incandescent. The total number of passengers carried by the former during the year was 1,309,240, being an average of some 3,586 per day, and the total receipts amounted to £9,013, an average of, say, £25 a day, or about 1½d. per passenger. Penny fares account for more than half of the total receipts. At the end of the year, the company was supplying current for 9,032 incandescent lamps and 35 arc lights, and the receipts from this source amounted to £7,513. Although based on a water-power station, the company's business increased so much that, owing to the dry season, an expenditure on coal fuel was made necessary of no less than 14 times as much as in the previous year. The financial results, however, were still favourable enough to allow of a 5 per cent. dividend, besides putting aside £1,000 to the reserve fund and a similar sum to replace the cost of special repairs during the year.

The Royal Society.—"Some time ago," says the *Chronicle*, "we mentioned a rumour that the 15 candidates selected by the Royal Society's council would be largely of the professorial and South Kensington order. This forecast was pronounced by a distinguished official as unfounded, since the selection had not then been *officially* made. The list is, however, now out, and, it is interesting to find, quite confirms the general talk in scientific circles, for the majority belong to the class who have long had almost absolute control of the society, while several names are quite unknown to us. We may now mention that some weeks ago three lists of probably successful candidates were drawn up, two by Fellows well acquainted with the personal leanings of the council, and one by an outsider, who judged the list of applicants solely by their merits. The result was that in one list appears 12 of the selected names, in another eight certain and two problematical, and in the third only six of the men now decided to have F.R.S. affixed to their names were considered worthy of that distinction. The society publishes the names of the selected candidates; why does it not give those of the unsuccessful ones? Then the public could judge for itself."

Douglas Electric Tramway.—A trial run in connection with the Douglas and Laxey Coast Electric Tramway took place on Thursday of last week. The tramway is being constructed by a company, and, when completed, will extend from Douglas to Laxey, seven miles distant. The route taken is for the most part by way of the precipitous sea cliffs that lie between Douglas and Laxey, and in connection with the tramway a very fine marine drive has been laid out. The first section of the tramway, extending from Douglas to the Glen of Groudle, is completed, and the cars ran the distance of four miles along the marine drive with remarkable smoothness. There was not the slightest friction observable, and the trial was a success. A large number of gentlemen, either connected with the company or with the engineers, made the journey, and expressed themselves as being well pleased with the working of the tramway. The current for working the line is generated at a large station in Douglas, and is conveyed to the cars by overhead wires. The tramway has been constructed and the electrical installation put in by Messrs. Mather and Platt, of Manchester, under the personal superintendence of Dr. Hopkinson. The completed section was opened for public traffic on Saturday, and it is expected that the whole line will be finished by July 1.

Lecture.—At the twelfth meeting of the Royal Scottish Society of Arts held in Edinburgh on Monday, Mr. Mathew Buchan read a paper on "The Practical Application of Electricity to Domestic and other Purposes." He referred to the introduction of electric current into the town, and said that the Corporation did not undertake to do more than the Gas Commissioners did now, and the installation of electric wires would in time become part and portion of the plumbers' trade; but his advice was that they should not be trusted with the work in the meantime. Wires, switches, cut-outs, and fittings must be installed by a private electric contractor, and the work must be done to stand the test of the Corporation's electrical engineer. Light for light the cost would be about 40 per cent. more than gas, but the saving in other directions by its use would materially reduce the price. Mr. Buchan displayed and described various styles of fittings, and explained the difference between the arc and incandescent lamp. Electricity as a motive power was next dealt with, and its advantages, such as absence of smell and noiselessness, were pointed out. The cost was about 50 per cent. greater than gas power. In conclusion, he showed how electricity was manipulated in order to produce heat for cooking and other domestic purposes.

Electric Installation by the Great Northern Railway.—In a recent issue we gave a description of the electric light installation carried out by the Great Eastern Company at Liverpool street. The Great Northern Railway Company are following suit by the construction of a central electrical station of their own, which is situated at Holloway between the Great Northern main line and the North London line. Current will be supplied from this for the arc lighting of the passenger station and goods yards at King's Cross. There are already 100 arcs in use in these goods yards. The Finsbury Park and Holloway stations are also to be lighted by arc lamps, and the company's offices and hotel will be lighted by incandescent lamps. The supply station is divided into two main sections—the boiler-house and the engine-house. In the former, which is 80ft. long by 43ft. wide, are five Lancashire boilers, 28ft. long by 8ft. in diameter. A Green's economiser is installed, and Bennis's mechanical stokers are fitted to the boilers. To avoid a breakdown, everything in the boiler-house is in duplicate. When everything is complete, the engine-house will contain 12 Fowler engines. Five of these, of 100 h.p. each, will work two dynamos apiece for the supply of arc lamps. Two engines of 100 h.p. have already been erected for the alternators. The main cables have been laid in a trench beneath the floor of the engine-house. From the works the cables run through the siding area to the Great Northern main line.

Royal Meteorological Society.—The monthly meeting of this society was held on Wednesday evening, Mr. R. Inwards, F.R.A.S., president, in the chair. Mr. W. Ellis, F.R.S., read a paper "On the Relative Frequency of Different Velocities of Wind," in which he discussed the anemometer records of the Greenwich Observatory for the five years 1888-1892, with the view of ascertaining the number of hours during which the wind blew, with each of the different hourly velocities experienced during the period. The results of this discussion show that the wind blew for the greatest number of hours with the hourly velocities of 10 and 11 miles. Mr. W. Marriott, F.R.Met.Soc., gave an account of a series of observations on the "Audibility of Big Ben at West Norwood," which he had carried on for a period of five years. The clock tower at Westminster is 5½ miles distant from the point of observation in a north-by-west direction. The large bell "Big Ben" was designed by Lord Grimthorpe, and was cast in 1858; its weight is about 14 tons. It is 9ft. 5½in. in diameter and 9⅜in. in thickness, its tone being E. The observations were 976 in number, and were made at the hours of 9 a.m. and 9 p.m. The bell could be heard more frequently in the evening than in the morning, and on Sundays it was more frequently audible than on weekdays. The direction of the wind most favourable for hearing "Big Ben" was between west and north. The observations were also discussed in relation to temperature, moisture, cloud, and barometric pressure. A paper by Mr. A. W. Moore, on "Earth Temperatures at Cronkbourne, Isle of Man, 1880-1889," was also read.

Electric Traction in Switzerland.—At a special meeting recently held in Lausanne of the committee formed to promote the more rapid development of electric tramway lines in the town, some additional particulars besides those already published were given by Prof. Palaz concerning the erection and equipment of a tramway from the Place Saint-François to La Pontaise. The total length of line first proposed is a little more than a mile, with maximum grades of 11·5 per cent., or, say, 1 in 9. The vertical height or difference of levels through which the cars are lifted is therefore about 250ft. The line is of metre gauge, and electric traction upon the overhead wire system is stated to be preferable to the use of a rack line, though no good reason appears to exist why the two should not be combined as on the line at Barmen. The cars are designed to carry 36 passengers each, with sitting accommodation for 24, and the minimum number of journeys per day will be 24 in winter and 36 in summer. For the full journey—occupying 20 minutes—a fare of 3d. is to be charged, with intermediate 1d. and 2d. stages. Each car is to be fitted with two electromotors, having a total maximum output of 50 h.p. Water power in this case would be too expensive, and probably oil or gas engines will supply the necessary motive power at the generating station. The cost of erection and equipment is estimated for the complete station at £10,000 to £12,000. Comparing results from similar enterprises, an average of half a million passengers would, it is estimated, give total receipts per annum equal to about £2,600, with an expenditure of £1,800, leaving a net profit of £800.

The Leeds Tramways.—We understand, according to a Leeds paper, that, in answer to the advertisement of the Leeds Corporation for offers to work the Leeds tramways on a lease, only three communications have been received. One of these is from the Thomson-Houston Company, who are working the Roundhay Park cars on the overhead system. The company intimate that the conditions to be imposed by the Corporation are such that they are not prepared to say what they will pay per mile for the right to work the undertaking, though they are willing to extend, for the Corporation or any other proprietors, their Roundhay Park electric system throughout the city. Mr. Graff Baker, who formerly managed the Roundhay Park section for the Thomson-Houston Company, submits two offers. In the first tender he undertakes, on behalf of a syndicate or company, to work the lines by electricity, the wires being overhead or underground, at £220 per mile for 21 years on the local authority's terms. As an alternative proposition, the company Mr. Baker represents say that if the Corporation do not require them to take over the existing plant, and will undertake to accept their (the company's) plant 21 years hence, they will pay £500 a mile for the right of working. The third offer comes from Mr. Graff Baker personally, and it is said to be a repetition of the tender of the company he acts for with these alterations—that he is willing to

Digitized by Google

give £300 instead of £220 a mile on the Corporation's stipulations, and £520 instead of £500 if he has not to be saddled with the existing plant, and may hope to sell his stock-in-trade to the Corporation 21 years hence. It is reported that the Tramways Committee are disappointed with this result of their endeavours to get the undertaking off their hands.

Arc and Incandescent Lamps.—In a recent issue of a French journal, M. A. Bainville compares the cost of lighting by means of incandescent lamps and arc lamps under different conditions of supply. He distinguishes between private generating stations where the cost of power is low, and central stations where it is generally much higher, taking the unit at 0·5d. and 3d. in the first case, and 6d. and 1s. in the second case. In making an estimate of the cost of arc lighting, he assumes the expense for carbon to vary from 0·11d. to 0·45d. per hour, according to the current employed, the extreme limits being three amperes and 20 amperes. The annual cost for renewals and repairs to arc lamps he takes at 30 per cent. on the cost of the lamp, this being estimated at £6. The labour required for cleaning and trimming the lamps he assumes at one hour for each lamp per day. A table is given showing the cost per spherical candle-hour calculated on the above basis. As regards lighting by incandescent lamps, the author distinguishes between four different cases when lamps are employed requiring 2, 2½, 3, and 4 watts per candle, having a life of 150, 300, 600, and 1,000 hours respectively. The resultant costs per spherical candle are given on the supposition that the light is required on an average for six hours per day. In comparing the results he finds that where the power can be obtained at the low rate of ½d. per unit, the three-watt incandescent lamp is, under all circumstances, more economical than the more efficient incandescent lamp or arc lamp. Where the power can be obtained at 3d. per unit, incandescent lamps consuming from 2 to 2½ watts per candle are the most economical. With power at 6d. per unit, the arc becomes more economical than the incandescent lamp when the light required from each exceeds 300 candles, and at 1s. per unit the limit is 150 candles, the most economical type of incandescent lamp to be used being that which requires two watts per candle. The general result of the author's investigation is that under nearly all circumstances the incandescent lamp is preferable to the arc lamp.

Engineering Laboratory at Cambridge.—On Tuesday last Lord Kelvin opened the new engineering laboratory at Cambridge University. There was no laboratory in the university until the present movement originated, three years ago, in the appointment of a committee, when Prof. J. A. Ewing was appointed to the chair of mechanism and applied mechanics, and a committee was formed to collect subscriptions for the building of the laboratory. The amount thus far realised is £5,000, and the list is still open, as one of the wings of the building remains to be completed, and much has yet to be done in the way of equipment. The subscriptions were supplemented by a grant of £1,000 from the funds of the university, which enabled the south wing to be built. In addition to actual money subscriptions, a large number of gifts of apparatus and machinery have been made by various engineers, including Lord Kelvin, Sir Joseph Whitworth and Co., Mr. C. A Parsons, Mr. A. A. Common, Mr. Alexander Siemens, and others. In many cases, too, manufacturers have supplied plant on exceptionally favourable terms. The laboratory is designed in three parts—a central block, with south wing and large north wing, which latter has still to be built. On the ground floor of the front block are two large rooms for electrical testing, as well as offices. Behind this block is the old hall of the Perse School, which is converted into a mechanical laboratory; beneath this is the heat laboratory; and lying off of this is a large laboratory for steam-engines and dynamos. The south wing includes classrooms and research laboratories. An adjoining site is reserved, to which, when funds allow, it is intended to remove the university workshops, which were established many years ago by Prof. J. Stuart. Instruction in the workshops is still part of the scheme of teaching in its now greatly developed form. The two together now form a very complete course of study of the scientific side of engineering as a preparation for professional life. The laboratory work has been going on in the old building for some time, but under great difficulties, on account of the inadequacy of the accommodation.

Transmission of Power from Niagara.—An elaborate estimate of the distance to which Niagara water power can be economically transmitted by electricity is given by Messrs. E. J. Houston and A. E. Kennelly in the *Electrical Engineer* of New York of May 2. After going into details, the authors conclude as follows: "The foregoing results indicate that on the basis of prices and voltages assumed and detailed, the power of Niagara Falls can be transmitted to a radius of 200 miles cheaper than it can be produced at any point within that range by steam-engines of the most economical type with coal at 3dol. per ton. That Niagara power can maintain at Albany a large day and night output cheaper than steam-engines at Albany can develop it, but that for power taken at Albany for 10 hours per diem the best steam-engines have somewhat the advantage over Niagara unless exceptionally favourable conditions of load could be secured for Niagara power. These conclusions are, of course, entirely dependent upon the reliability of the prices, voltages, and estimates as detailed above. The prices, however, appear to be conservative, and are probably in excess of the latest market values. This would also appear from the statement recently published that the Cataract Construction Company has contracted for the privilege of right of way for conducting lines along the Erie Canal banks, by supplying power for barges at the annual rate of 20dol. per horse-power (26·81dol. per kilowatt), whereas the above figures make the average cost of production 20·792dol. per horse-power (27·872dol. per kilowatt) on the basis of an average output of 0·6 full load; so it would appear that the Niagara Power Company are in the possession of better prices. Moreover, if the voltage delivery on the long lines, here taken at 35,350 at the receiving end, can ever be safely increased, a marked reduction in the cost of delivery would naturally result. The broad conclusion to which an enquiry of this nature inevitably leads, is that while under ordinary conditions the commercial limit of electrical transmission of power from water powers of less than 500 kilowatts can hardly exceed 50 miles, the radius at which it will be profitable, with good fortune and management, to electrically transmit a water power aggregating 50,000 kilowatts, or more, is, perhaps, to-day, 200 miles, and that it might be commercially advantageous for such a large water power to undersell large steam powers at twice this distance with no profit, in order to reduce the general expense upon delivery nearer home. The reason for this difference in the transmission radius between small and large water powers, lies obviously in the fact that electrical and hydraulic machines can be built and purchased much more economically in large sizes than in small, so that the cost of producing and of maintaining one kilowatt is very much less for large than for small water powers."

ELECTRICAL EXHIBITION AT DERBY.

An electrical exhibition, to which we referred in a previous issue, was opened by the Mayor (Mr. J. P. Doherty) on Monday in the Lecture Hall. The object of the exhibition, which has been promoted by the Electric Lighting Committee of the Town Council, is to popularise the applications of electricity in the district, and for another two weeks the inhabitants will have an opportunity of seeing for themselves the advantages of electricity for lighting, heating, and power purposes. The engineer and manager is Mr. J. E. Stuart, A.I.E.E. The municipal electricity works were started on October 10, 1893, and were described in the *Electrical Engineer* at the time. The demand for the supply of current has increased continuously ever since the opening of the station, when there was current going out to only two consumers who were then connected to the mains, these two having between them about 180 8-c.p. lamps. There are at present over 65 consumers connected to the mains, and these have a total equal to over 3,000 lamps. Twenty to thirty consumers, with a number of lamps equal to another 5,000 8-c.p. lamps, are waiting to be connected to the mains, or are having their premises wired. This would represent the entire output of the station as it now stands, and it is for this reason, and in view of further pending enquiries and applications for the supply of current, that a new 250-i.h.p. engine and dynamo are now being added. The amount received for current from the opening day—October 10, 1893—to March 31 last, with an average taken over the whole period of only about 1,500 8-c.p. lights connected, was £474. 7s. 10d. The public street arc lighting has also been very successful. Lamps are being continually got into place, and shortly there will be in all nearly 80 lamps burning at one time. It is estimated that to the same date—*i.e.*, March 31 last—and when charged at the rate common for such lamps as those in Derby—of £25 per lamp per annum, each lamp burning for, say, 3,000 hours—as much as £505. 15s. has been earned for public lighting. The demand for current to be used for power and for purposes other than lighting has not, up to the present, been as extensive as it will be in the near future. This is probably owing to the fact that customers do not yet fully appreciate how useful an agent electricity is for producing motive power. One of the main objects of the exhibition is to impress this fact upon consumers.

The Electrical Company, Limited, of Charing Cross-road, London, W.C., occupy the first stand with exhibits comprising a search-light, Luna arc lamps for direct and alternate current, German Edison incandescent lamps of any voltage and candle-power for every socket in the market, lampholders, main, branch, and combination switches, safety fuses, installation material, cables, wires, flexible cord, electroliers, testing instruments, voltmeters and ampere-meters, reading telescopes with scales, Stabilit insulating material, storage batteries, and electric heating and cooking apparatus.

Messrs. Walter T. Glover and Co., of Salford, Manchester, are ably represented at the second stand by samples of cables for electric lighting, telephones, and torpedoes, armoured and lead-covered cables, concentric, and other varieties.

Messrs. Pyke, Harris, and Co., Limited, 34-36, New Tothill-street, Westminster, London, S.W., show at the next stand high-tension apparatus, illustrating various degrees of illumination produced in vacuum tubes under similar inductive influence, the gaseous vacuum being different in each case. There are also to be found a high-tension transformer, a small "Combination" transformer, and an alternating-current dynamo designed to work on the inductor principle.

Messrs. C. A. Parsons and Co., of Heaton Works, Newcastle-upon-Tyne, have on view a 1½-unit steam-turbine dynamo, and a six-unit Heaton dynamo having an output of 92 amperes at an E.M.F. of 65 volts. There are also exhibited an Admiralty type projector, a 10-h.p. kilowatt transformer, and a 3-h.p. kilowatt transformer.

Messrs. Crompton and Co., of London, show their well-known electric heating and cooking apparatus. These are on view in Room No. 5; and demonstrations, with cookery lectures, are given daily at 3 and 7 p.m. by Mrs. Mary Seaton. Lectures on the practical application of electricity for domestic purposes (particularly with regard to cooking) will be given at intervals during the exhibition by Mr. H. J. Dowsing, M.I.E.E.

Messrs. W. T. Henley's Telegraph Works Company, Limited, of 27, Martin's-lane, London, E.C., exhibit samples of various insulated cables for electric lighting, submarine telegraphy, telephones, torpedoes, etc., fancy coloured electric light cords, jointing materials, lamps, etc.

Messrs. F. and C. Osler, of London and Birmingham, display a variety of electrical fittings intended to illustrate two methods of lighting a drawing-room. This is accomplished, first, by means of a group of lights in a richly cut-glass dish (with a silvered reflector inside) fixed near the ceiling, supplemented by movable standing lights on the piano, on occasional tables, or elsewhere. The second method shown is by means of single pendants suspended from the ceiling at suitable points.

The General Electric Company, Limited, of 71, Queen Victoria-street, E.C., show a variety of electric heating and cooking apparatus. Among these may be mentioned coffee machines, hatter's iron, cigar lighters, glue-pot, a ⅛-h.p. motor and one of ½ h.p., fan and guard, curling-iron heater, kettles, frying-pans, saucepans, steam cooker, ovens, griller, etc.

The Edison and Swan United Electric Light Company, Limited, of 100, Victoria-street, Westminster, S.W., exhibit samples of various descriptions of incandescent lamps of all candle-powers, and electric light fittings of high class—for instance, ship-light fittings, casings, cut-outs, switches, switchboards, holders, motors, and cables—whilst shades of several designs, and for all purposes, are also to be found.

Messrs. John Davis and Son, of All Saints' Works, Derby, and 118, Newgate-street, London, make a display of large arc lamps and miniature arc lamps suitable for lighting interiors of churches, shops, etc., electroliers and brackets, electric motors, advertising signs and devices, cooking and heating apparatus, engraving machines, ventilating fans, carved and enriched casing for leads, switches and switchboards, incandescent lamps and shades in great variety, and telephones.

Messrs. Siemens Brothers and Co., Limited, exhibit a selection of cable samples, leading-wire samples, rubber samples, ebonite samples, and electric light fittings for ship work. There are also on view Siemens's incandescent lamps, Hellesen's dry cells, Obach's dry cells, and other forms of cells for telegraphic purposes, and a selection of electric light carbons, switches, and cut-outs.

Mr. Henry Baker, of 30, London-road, Derby, exhibits an assortment of electroliers, electric pendants, brackets, fittings, etc., a variety of electric lamps, lampholders, switches, cut-outs, fuses, cables, wire, lamp-shades, and other accessories for house and shop lighting, and electric signalling apparatus.

On Wednesday evening Sir Frederick Bramwell, Bart., delivered an address on the applications of electricity.

ANOTHER ELECTRIC LOCOMOTIVE.

The accompanying illustrations—reproduced from the *Railroad Gazette* of New York—show the general form and construction of an electric locomotive now being built by the Paris, Lyons, and Mediterranean Railroad, after the designs of Mr. H. Bonneau, chief engineer of the road, and Mr. E. Desroziers, for trial in fast passenger service.

The locomotive, as will be seen from the engravings, has four driving wheels, a four-wheel leading truck and a two-wheel trailing truck, the drivers and trailing truck being so mounted as to form a rigid wheel base of 15ft. 7in. supporting the frame by half elliptic springs. The springs of the trailing truck are placed above the boxes, while the driver springs are underhung and equalised. The leading truck is mounted somewhat after the fashion of Webb's well-known radial axle, with a considerable range of lateral motion, being held normally in a central position by means

Digitized by Google

of springs. In order to gain a maximum amount of space for the driving mechanism, the frames, which are of plate construction, are placed outside the driving wheels.

The motors are slow-speed six-pole machines of the Desroziers pattern, a separate motor being mounted on each axle. The armature shafts are hollow, their internal diameter being sufficient to give considerable clearance to the driving axles which they surround. It will be observed from the cross-section that the commutator of this motor is close to the armature and surrounded by the pole-pieces. It is claimed that this construction permits the use of a more powerful motor than would otherwise be possible in the limited space between the drivers. The brushes are easily reached through the openings between the pole-pieces. The field magnets are supported by heavy lugs on the motor frames bearing on vertical rods, the heads of which are cup-shaped as to permit a slight lateral motion of the motors. These rods are supported on U-shaped girders fastened at the upper ends to the frames, but are provided with buffers of Belleville washers in order that shocks may not be transmitted vertically from the frames to the motor. The motor is thus supported clear of the axle and transmits motion to the drivers through the system of drag links shown in Figs. 2 and 3. A double-plate ring surrounds the axle and is connected to it by means of two short rods or links placed diametrically opposite to one another. Two similar rods perpendicular to the first connect this ring with the driver. In order to give this connection the greatest possible freedom of motion, ball bearings are provided at the ends of each rod.

Beneath the motors and secured to the U-shaped girders is a casing of sheet iron and wood of sufficient length to protect both motors from dirt and moisture, and carried up to the frame at the sides and ends. The upper part of each motor is left uncovered, with the exception of the armature, which has a light iron casing. A light cab covers the whole locomotive, thereby protecting the motors and apparatus.

In order to avoid, if possible, the necessity of erecting conductors along the road, especially for branch lines, the railway company proposes at first to experiment with storage batteries, arrangements being made for carrying them over the leading truck of the locomotive. The necessary apparatus for controlling the supply of current, and for the application of brakes, is placed also at the front of the locomotive, where the engineer will have an unobstructed view of the track ahead.

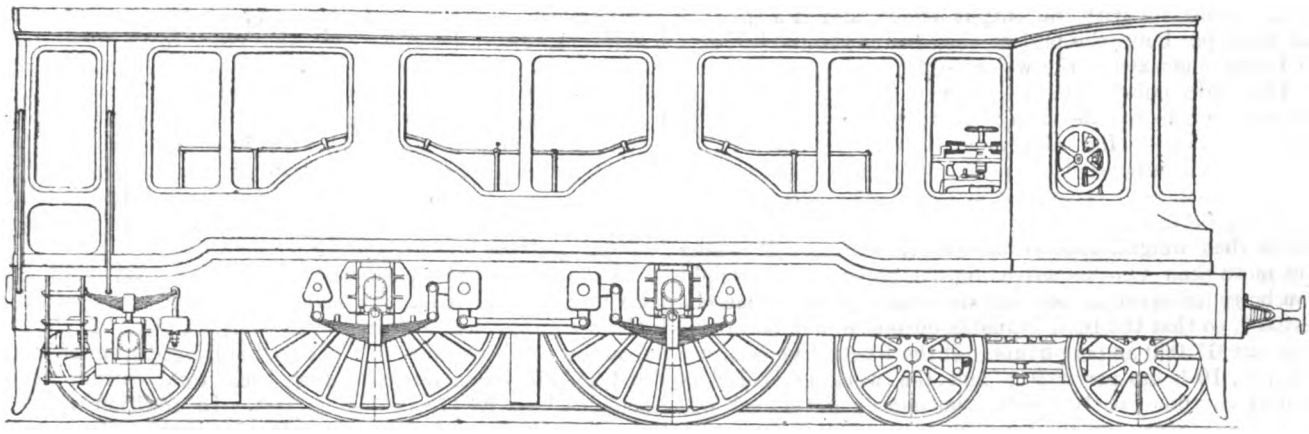

FIG. 1.

The general dimensions and weights of this locomotive are given as follows:

Driving wheel base	8ft. 6⅜in.
Rigid wheel base	15ft. 7in.
Length over buffers	37ft. 1⅛in.
Diameter of drivers	7ft. 8½in.
Diameter of trailing truck wheels	4ft. 7⅛in.
Diameter of leading truck wheels	4ft. 1½in.
Weight on drivers	63,933lb.
Weight on leading truck	28,660lb.
Weight on trailing truck	44,092lb.
Weight of frame and accessories	70,548lb.
Weight of motors	55,115lb.
Weight of apparatus	2,204lb.
Weight of storage batteries	8,818lb.
Total weight	136,685lb.

It is calculated by the designers that the locomotive above illustrated will have a maximum power of 1,200 h.p. The first locomotive is to have a power of only about 300 h.p.

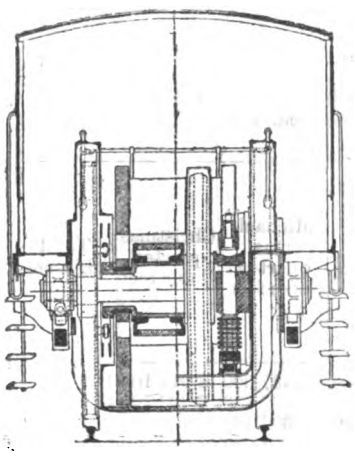

FIG. 2.

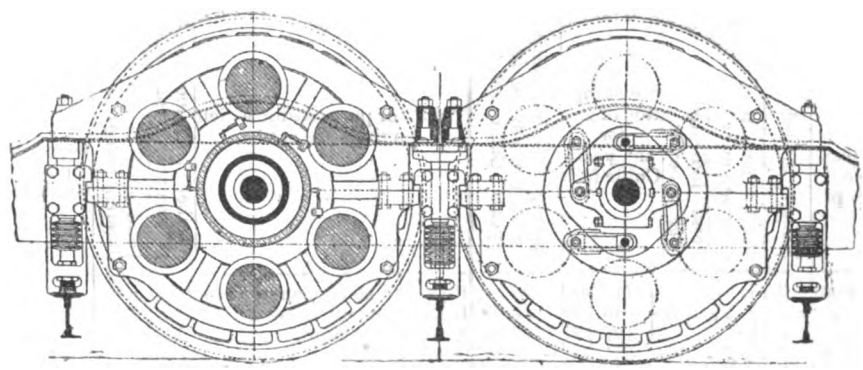

FIG. 3.

The details thus given of the new locomotive are not, perhaps, very clear; certainly they are hardly sufficient to enable an accurate idea to be obtained of the full powers and qualities of the device. Even the few particulars herein set forth, however, merit considerable criticism, more especially as electric traction is not yet in a position to be trifled with by ill-planned schemes of an over-ambitious nature.

No details are offered as to the speeds obtained with this locomotive, either normal or maximum; but as it is intended for fast passenger service, probably we shall be safe in assuming an average velocity of 45 miles per hour. This implies a speed of rotation in the driving wheels of about 160 revolutions per minute—quite a normal speed for motors of this type, considering the large output claimed for them. When, however, the weight is taken into account, we can only say that the design of these motors

Digitized by Google

must be very excellent indeed when an output of 1,200 h.p. is obtained from them.

As a general rule, large electric motors under the most favourable circumstances, require a weight of, say, at least 1cwt. per horse-power developed, so that the result in this case is most favourable when a weight of not quite 25 tons in the motors gives an output of 1,200 h.p., or more than twice the usual proportion! It would seem almost more than probable that some mistake has been made in regard to this point, for with the output named, and at a speed of 45 miles per hour, the pull on the level is about 11,000lb., or barely one-sixth of the weight on the drivers.

The main point, however, deserving of criticism is the proposal made by the designers to use accumulators or storage batteries for supplying electric energy to the motors. To suppose that rather less than four tons of accumulators will propel at high speeds a locomotive weighing 68 tons, and a train of perhaps twice or three times that weight, appears absolutely absurd. Probably not more than two ampere-hours per pound gross weight can be relied upon as the output from a good commercial battery, so that the total available output would be in this case, say, 17,000 ampere-hours. If the locomotive is in use for, say, 10 hours per charge, and the working E.M.F. of motors be taken at 100 volts, the energy developed will not exceed 250 h.p., an amount which will obviously be insufficient to propel such a train at high speeds.

It will be found in practice, moreover, that unless these battery locomotives be confined to one locality of limited area—be used, for instance, to carry out shunting operations—the cost of erecting stations at different points to recharge the batteries would probably exceed any outlay required for line conductors. The trolley wire, or its kindred types, cannot be beaten for cheapness, either for capital outlay or working expenses.

GAS-ENGINES.

In the course of his inaugural address last week before the Incorporated Institution of Gas Engineers, Mr. Alfred Colson (the new president) made the following remarks concerning the use of gas-engines.

Estimates have from time to time been made of the quantity of gas used by cooking-stoves, but I know of none with regard to that taken by the total number of engines in use in any large town. A favourable opportunity has also been afforded me for arriving at this, inasmuch as we let on hire wet meters only, which has necessitated the purchase by the consumers of the dry meters required in connection with the engines. The result is that, with scarcely an exception, we have in our books a separate registration of the gas used by every engine in the town. Table A, given herewith, for the year 1893, gives the various sizes of engines in use, the number of each size, together with the total horse-power, also the average and total consumption of gas per engine, and, in addition, the number of engines employed in different trades, and the quarterly and year's consumption of gas by each trade. For the engines fixed during the year, the full 12 months' consumption has been calculated from the actual quantity of gas consumed by each for the time being.

The table includes particulars referring to 377 engines, varying in size from one man power to 20 h.p. nominal, which engines are working most satisfactorily. It shows that the year's consumption per engine ranged from 23,050 to 1,358,800 cubic feet, and that their total consumption amounted to 82,418,100 cubic feet. In addition to the engines enumerated in the table, there are 36 others, equalling 253 h.p. nominal, which have been fixed during the present year, including five of 20 h.p. each. The consumption of gas by these will amount to at least 10,000,000 cubic feet per annum; making a total annual consumption of 92,000,000 cubic feet, the greater proportion of which will be used during daylight hours. This quantity amounts to 8·52 per cent. of last year's consumption for all purposes. I find that the engines at present are working at scarcely half their limit; for supposing them to work for 54 hours per week, as they nearly all do, and allowing 20 cubic feet of gas per indicated horse-power per hour, the consumption of gas would be over 200,000,000 cubic feet per annum. Here, then, is a source of increasing consumption without considering any prospective increase in the number of engines. It is quite evident from these figures that no pains should be spared on our part to secure the success of every gas-engine put down by seeing that mains and services are sufficiently

large, and the pressure ample for ensuring at all times an adequate supply of gas. I attribute in a measure the success of the gas-engine in Leicester, where its use is rapidly extending, to the careful attention that is paid to these requirements. As to the day pressure under which gas is supplied, my practice does not accord with the advice given in the well-known "golden rule" relating thereto. Until 10 years ago the rule referred to was carefully observed, with the object of keeping the "unaccounted-for" at a minimum; but so much trouble and annoyance were experienced with regard to the supply to both engines and cooking-stoves during the daytime, that the pressure was gradually increased from 10-10ths to 19-10ths, and with the best results. It may surprise some to learn that this increase of pressure has led to no increase in the "unaccounted-for," the average of which for the last 10 years, under the higher pressure, is 2·67 per cent.; while for the previous six years, under the lower pressure, it was 3·16 per cent. It is needless to say that the distributing plant is in first-class condition.

THE ELECTRIC MOTOR.*

BY PROF. F. B. CROCKER, COLUMBIA COLLEGE.

A single lecture cannot possibly do justice to a subject of the magnitude and importance of the electric motor. There are, however, certain salient and interesting points which, when touched, give the keynotes of the entire subject. Some of these are contained in the history of the electric motor, and others in the action of the machine itself.

In taking up the historical consideration, we have the amber of the ancients as the first electric generator, corresponding to the dynamo, and its attraction of feathers and other light bodies as the first artificial production of motion by electricity, corresponding to the electric motor. I say artificial, because lightning has from the beginning of the world caused powerful movements and disturbances in the bodies which it strikes. Thus the birth of these two important machines was simultaneous; indeed, electricity was discovered solely by the fact that it produced motion under conditions which were peculiar, and it seemed to be so different from all other natural phenomena that from those early times, even up to the present day, it is looked upon as the most wonderful and mysterious agency in Nature.

The magnetic attraction of pieces of iron by the lodestone was also observed by the ancients, and the electric motor of the present day is more directly based upon this phenomenon than upon the electrostatic attraction caused by amber.

From those early times up to the present century, particularly during the last century, numerous experiments were made with magnetic and electrostatic attraction, but no one produced any results which can be considered to be any more like an electric motor than the simple experiments of the ancients. The first apparatus which in principle and construction sufficiently resembled the machines of to-day, to be properly regarded as an electric motor, was Barlow's wheel, described by him in his work on "Magnetic Attraction," published in London in 1823. This invention is remarkable in the fact that it antedated by eight years the disc machine of Faraday (which was the prototype of the dynamo), and his discovery of magneto-electric induction in 1831. Not only was Barlow's wheel far ahead of Faraday's disc in point of time, but it was also a much better construction, because the former was made in the shape of a star with long points, so that the current was confined to the particular portion of the wheel which was between the poles of the magnet. In Faraday's disc, on the other hand, the current produced in that part of the disc actually between the poles was at liberty to flow back through all the rest of the wheel. The armature was, therefore, completely short-circuited in itself, a feature which we know to be one of the worst faults that it can possibly have, and the amount of current obtained in the external circuit was an almost infinitesimal fraction of that produced, being only sufficient to deflect a galvanometer needle. It was, indeed, a fortunate thing for science that any perceptible effect whatever was obtained, otherwise the most important discovery of the nineteenth century might have been delayed.

Joseph Henry, in 1831, was the first to construct a motor which worked by electromagnetic attraction. This apparatus really has a better right to the distinction of being called the first electric motor than Barlow's wheel. Many other inventors followed Henry in devising forms of electromagnetic motors. Jacobi in 1834, Davenport in 1837, and Page in 1838, are particularly worthy of mention. Some of these early motors were by no means mere toys, but were of considerable size and power. Jacobi, of St. Petersburg, in 1838, propelled a boat 28ft. long at a speed of three miles an hour; and Page, of Washington, in 1851, succeeded in obtaining a speed of 19 miles per hour with a car carrying a number of persons and driven by a 16-h.p. electric motor. This result, by the way, is practically the same as that obtained from the most improved trolley cars of to-day, both in speed and power.

This brief glance at the early history of the electric motor brings out the striking fact that this machine was invented eight years before the dynamo and for several decades it was considered of more importance, both scientifically and practically; the motors of Jacobi and Page, for example, being far more powerful than any contemporaneous dynamo. A search through the patent records of the United States and England would show also that more attention and greater expectations were then based upon the motor. This was undoubtedly due to the fact that inventors hoped to obtain a source of power which would rival or surpass the steam-engine. It was gradually realised, however, that the cost of electrical energy obtained from a primary battery is so high that it cannot compete with a steam-engine. The number of pounds of zinc consumed in the best battery per horse-power hour is about equal to the weight of coal required to give the same amount of energy in a steam-engine; and since zinc costs about 50 times as much per pound as coal (in fact, it actually requires several pounds of coal to produce 1lb. of zinc) it is obvious that the primary battery is far more costly than steam in the generation of power. As a matter of fact, electrical energy from a primary battery at the present time costs at least 10 times and probably 20 times as much as that obtained by the use of a steam-engine and dynamo.

The realisation of this serious difficulty greatly discouraged scientific men and inventors in regard to the electric motor. A reaction set in against it, and for many years it was comparatively neglected by the best workers. The dynamo was taken up in its stead and developed in the remarkably rapid and successful manner which is the greatest practical achievement of recent times. The neglect of the electric motor continued until about 1887, the dynamo having by that time reached a state of great perfection and being in extensive use for electric lighting. The development of the dynamo, and the laying of electric light circuits through the streets of many cities and towns, provided the very supply of reasonably cheap current which was needed for the motor, and which the primary battery had failed to give.

This fact encouraged inventors and manufacturers to again take up the motor, and since that time its progress in this country has been very rapid; but even now the motor is somewhat overshadowed by the dynamo. The number of electric motors in use in foreign countries is not very considerable, but in the United States there are probably about 50,000 stationary motors and several thousand railway motors, whereas the number in the whole of Europe is not much more than one-tenth of these figures. This last fact probably explains why the literature of the dynamo is much more complete than that of the motor, since most of the books are written by Europeans—the time of Americans being occupied rather with making and using dynamos and motors than with telling others how to do these things. The most recent history of the motor includes the invention, by Tesla, in 1888, of the two-phase alternating-current motor and the development of the two and three phase systems. These important systems are now being practically used, and an enormous electric power transmission

* Lecture delivered before the Franklin Institute, Philadelphia, January 19, 1894.

plant is being installed at Niagara Falls, which is to be operated by the two-phase system. Indeed, it may be said that the progress of the electric motor at the present time is equally as rapid as, and more interesting than, that of the dynamo.

If the dream of the electrical engineer should be realised and electrical energy could be obtained directly from coal without the use of the steam-engine and dynamo, then the importance of the electric motor would be paramount, and it would be used in practically every case where power is needed, while the steam-engine and dynamo would be relegated to scientific museums where they would be gazed upon as mere historical curiosities. This time may come in a few years, or perhaps not for centuries, but no one will dare deny its possibility, and many of the greatest thinkers and experimentalists are now working in that direction.

The points in the history of the electric motor to which I desire to call particular attention are these: that for many years it was considered of greater importance than the dynamo; that it then fell into a position of comparative insignificance, but that in the last few years it has again become very prominent, and in the future it is certain to be of still greater importance, while the dynamo may become obsolete.

In considering the construction and action of the electric motor, the first and most important fact is its great similarity to the dynamo, or, more strictly speaking, it is practically the same machine used in exactly the opposite manner. The dynamo is a machine which generates electric current when driven by mechanical power. A motor is a machine that develops mechanical power when supplied with electric current. Thus the functions of the two machines are exactly the converse of each other; nevertheless, identically the same machine can be used for either purpose—that is to say, the machine is perfectly reversible. It is also a fact that a machine that is good for one purpose is good for the other. The old idea that a good dynamo was not necessarily a good motor, and that considerable differences in construction are required, is, so far as the writer's experience goes, a fallacious one. The tendency now is for manufacturers to make exactly the same machine and use it for either purpose indiscriminately with only very slight differences in the details of winding, connections, etc.

While it is true that the two machines are practically identical in construction, nevertheless, their actions are somewhat different, and this difference is just sufficient to be puzzling. It seems to be a fact that knowledge concerning the motor is much less general and much less perfect than knowledge of the dynamo. The reason for this is probably that most persons fail to understand these slight differences in action, and are therefore apt to assume either that the two machines are exactly alike or entirely different, neither of which assumptions is correct.

The key to the action of the motor, and particularly to the difference between it and the dynamo, is its counter E.M.F. In the case of the dynamo there exists only one E.M.F., whereas in the motor there must always be two. The difference between the two cases may be expressed very simply in the following way:

One-kilowatt dynamo,

$$C = \frac{E}{R} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$10 \text{ amperes} = \frac{100 \text{ volts}}{10 \text{ ohms}}.$$

One-kilowatt motor,

$$C = \frac{E - e}{R^1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$10 \text{ amperes} = \frac{100 \text{ volts} - 90 \text{ volts}}{1 \text{ ohm}}.$$

C is the current;
E the direct E.M.F.;
e the counter E.M.F.;
R the total resistance of the circuit;
R^1 the resistance of the armature.

The current and direct E.M.F. are the same in the two cases, but the resistance is only one-tenth as much in the case of the motor, the difference being replaced by the counter E.M.F. of 90 volts, which acts like resistance to reduce the current.

The counter E.M.F. of a motor is the necessary result of the rotation of its armature, as I will now show you by the following experiment. We have here two identical machines, one of them being connected to the electric light circuit, the current from which causes the machine to run as a motor. This machine is belted to the other machine, which is thereby driven as a dynamo. Now in both cases we have identical armatures revolving at equal speed in magnetic fields of practically the same strength. It is obvious, therefore, that nearly the same E.M.F. must be generated in each machine, because in both cases practically the same number of lines of force are cut by an equal number of turns of wire revolving at the same speed. In the case of the dynamo this E.M.F. produces a current which may be used to feed a certain number of incandescent lamps In the case of the motor the E.M.F. is opposed or counter to the direct E.M.F. of the electric light circuit, and the current produced is due to the difference between the two, as expressed in equation (2).

It may be asked why this E.M.F. is necessarily a counter one. The answer is that if we trace out the direction of the motion and of the lines of force, we shall find in every case that the E.M.F. generated is opposed to that which produces the rotation of the armature. This, in fact, necessarily follows from Lenz's law. The real significance of the counter E.M.F. is that it represents the amount of electrical energy that is taken out of the electrical circuit, so to speak, and converted into mechanical energy.

This is the way in which Nature always works in converting electrical energy into any other form of energy, with the single exception of the production of heat by the passage of current through a resistance. This last, however, is not a true case of conversion, being a frittering away of energy similar to the production of heat by friction. In all other cases the counter E.M.F. is always present. For example, when electrical energy is converted into chemical energy in the charging of a storage battery, or the decomposition of water, there is in every case a counter E.M.F. In the same way, when an electromagnet is charged and electrical energy is converted into magnetic energy, there is a counter E.M.F. which opposes the magnetising current, and is commonly known as the counter E.M.F. of self-induction. Even when electrical energy is converted into heat by the Peltier effect there always exists a counter E.M.F. which represents the conversion of energy; this being a reversible process, and therefore, a true case of conversion, which, as already stated, is not the case when heat is produced by mere resistance. This counter E.M.F. is indeed a most remarkable and interesting phenomenon, and throws considerable light upon the relation of the various forms of energy and the manner in which one is converted into another.

In the case of the motor, the counter E.M.F. actually represents the amount of electrical energy converted into mechanical energy, and therefore determines the efficiency, the so-called electrical efficiency, or conversion-factor, being equal to

$$\frac{\text{Counter E.M.F.}}{\text{Direct E.M.F.}}$$

The actual or commercial efficiency is somewhat less than this owing to friction, Foucault currents, and hysteresis. The counter E.M.F. also determines the speed and many other facts in the working of the machine.

In the minds of many persons the counter E.M.F. is thought to be merely a "scientific idea" or a mathematical abstraction which has no real existence or importance. Nothing could be more erroneous than any such opinion. The counter E.M.F. is just as real as the direct E.M.F. We have already seen that it must necessarily be produced whenever the armature revolves. It is somewhat difficult, however, to actually measure or show it. From its very nature it is covered up, so to speak, by the direct E.M.F. The ordinary way to determine it is to find the value of the direct E.M.F., the resistance, and the resulting current; the counter E.M.F. is then found by the following equation, which is derived from equation (2): $e = E - CR$. It is also possible to calculate it in the same way that the E.M.F. of a dynamo is determined, if the number of turns

Digitized by Google

of wire, speed of rotation, and number of lines of force are known.

The following experiment actually shows the existence and value of the counter E.M.F. We have here a plain shunt-wound motor provided with a flywheel, and we run it from a constant-potential circuit of, say, 110 volts, and while it is running at full speed it is entirely disconnected from the circuit, but it will continue to run by the energy of the flywheel, and it will then act as a dynamo and generate an E.M.F. of nearly 105 volts, which is tested by connecting a voltmeter to the two brushes. This E.M.F. is practically identical with the counter E.M.F. which the machine was producing the moment before while running as a motor, provided, of course, the test is made immediately, so that the speed does not have time to fall appreciably. It should be remarked also that the strength of the field magnetism is slightly less, owing to the fact that it is fed by the E.M.F. of 105 volts generated by the machine itself, instead of by the 110 volts of the circuit; but if the magnetism is nearly saturated this will only reduce the number of lines of force 1 or 2 per cent. Several incandescent lamps can be connected in parallel across the terminals of the machine, and the energy in the revolving flywheel is sufficient to keep them glowing for one or more minutes. If a lamp is kept connected across the terminals of the motor while the switch controlling the circuit is alternately opened and closed, it is possible in this way to compare the direct and counter E.M.F. by the variation in the brightness of the lamp, and it will be seen that the latter is only slightly less than the former.

A still more striking demonstration of the reality of the counter E.M.F. will now be given by running the motor with a certain amount of resistance in its shunt field circuit, so that the field magnetism will be below its normal value, in which case the speed will be higher than usual. If the machine is now disconnected from the circuit, and the resistance is afterwards cut out of its field circuit, the E.M.F. produced will become actually higher than the original direct E.M.F.; in fact, it is possible to obtain two or three times the original voltage. We have here a new method of converting electrical energy to a higher potential, being a sort of direct-current transformer, which, however, is quite different in principle from the ordinary dynamotor.

The important matter of governing the speed or power of electric motors depends largely upon the phenomenon of counter E.M.F. For example, the various methods of regulating street-car motors—*i.e.*, the simple rheostat, the "loop" for short-circuiting one of the field coils, the "commutated fields," and the "series parallel controller" all act to adjust, or make up for, the variations in counter E.M.F. which result from changes in speed. The most awkward matter in working electric motors is to control the current when the counter E.M.F. is very low, due to the fact that the motor is starting or running slowly, and up to the present time there is no very satisfactory solution of this problem. The introduction of resistance in series with the armature is usually the simplest and most successful plan, but this is very wasteful of energy and involves the use of a large and clumsy rheostat.

The paradoxical fact that the speed of the ordinary shunt-wound motor increases if its field magnetism be weakened is also due to the counter E.M.F. This is easily understood if we remember that the counter E.M.F. is reduced by weakening the field magnetism, consequently the current is increased in strength, as is evident from equation (2), and the speed therefore rises until the counter E.M.F. reaches a sufficient value to shut off the excess of current.

The writer showed, several years ago, in his lectures at Columbia College, that a motor can easily be designed to run at the same, or at a higher, speed, when fully loaded than when lightly loaded. This may be done by slightly exaggerating the effect of armature reaction, so that the field magnetism will be considerably reduced by the large armature current which flows at full load, thus diminishing the counter E.M.F. and increasing the speed in the manner just explained. In this way the remarkable effect of greater speed with heavier load is obtained without any special device or construction, all that is necessary being a slight modification in design involving no increase in cost or complication.

These examples demonstrate the great significance and importance of the phenomenon of counter E.M.F. in the action of the electric motor.

THREE-PHASE TRANSMISSION PLANT AT TAFTVILLE, CONN.

The first important application of electrical power transmission to textile manufacture has just been installed by the General Electric Company at Taftville, Conn., the power being transmitted from Baltic to Taftville, a distance of nearly 4½ miles. It is a typical transmission by three-phase currents, in which motors of the synchronous type are used not only to operate one of the most interesting cotton mills in this country, but also the power station of the Norwich (Conn.) street railway. Mr. E. P. Taft, the founder of the Taftville cotton industry, long ago recognised the value of the available water power at Baltic, on the Shetugket River, near to which stood a ruined mill destroyed by fire some years ago, and having secured the property, with the water rights, determined to utilise the power as soon as a successful plan was offered.

Our contemporary the New York *Electrical Engineer* states that the Ponemah Mills are situated at Taftville, also on the Shetugket, and about three miles distant from Norwich. The original mill was operated for nearly a score of years by water power taken directly from the river, and when the new mill was erected it was found necessary to drive it from two 350-h.p. Corliss engines, the existing dam being insufficient in capacity. The generating station is at Baltic and the receiving station at Taftville. The rebuilt mill at Baltic contains in the basement the wheel and dynamo rooms of the generating plant The mill is of four storeys, built of stone, and will presently be used, as the Ponemah Mills, in the cotton-weaving industry. Four hundred feet above the mill a fine stone dam, 625ft. long, has been thrown across the river. The effective head on the turbines is 32ft., and the water available, even in the driest seasons, is sufficient to furnish not less than 1,500 h.p. The turbines are belted to pulleys on the main shaft, extending the whole length of the wheel-room, and continuing through the partition walls into and along one side of the generator-room. The pulleys are thrown into or out of action by Hunter clutches mounted with pulleys on quills, so that any or all of the wheels can be applied to driving the shafts. Similar pulleys and clutches are furnished in the dynamo-rooms for throwing in or out the various machines that may there be placed. The wheel-room contains three double 42in. horizontal wheels, and one double 27in. wheel, the former developing 800 effective horse-power each at 157 revolutions per minute, and the latter 300 h.p. at 244 revolutions per minute. The belts pass obliquely upward to the pulleys on the line shaft, and the turbines are kept at speed by Schenck electric governors, which have proved themselves capable of doing very fair service. The wheel plant and shafting were made and installed by the P. C. Home Company, of Gardiner, Maine. The line shafting is supported by heavy iron girders set on stone piers, and additionally braced by timbers.

The dynamo-room, beside the shafting, is occupied by two 250 kilowatt General Electric three-phase generators, delivering current on the line at 2,500 volts. Each machine is provided with its own exciter, a three-kilowatt bipolar dynamo. The three-phase machines run at 600 revolutions per minute, and are set so firmly on substantial foundations as to run with scarcely a perceptible vibration. The driving pulleys on the main shaft are fitted with Hunter clutches, so that either machine can be dropped out without the slightest disturbance to the service. The generators are connected to a common switchboard, and may be run in parallel whenever desirable. To this end the board is furnished with synchronising apparatus, the acoustic synchroniser being mounted on the face of the switchboard, and the equalising switch being at the back. The most interesting novelties in this switchboard are the high-voltage

Digitized by Google

switches on the lower part of the board. These are mounted on marble bases with substantial barriers erected between the switch blades, so that the circuit at full load and voltage may be broken without the slightest danger of arcing across from point to point. They have been amply tested, and have proved their ability to cope with the trying work required of them with the greatest ease. The generators fall into parallel easily and run as smoothly together as would a couple of railway generators. No artificial load is used in throwing them together, none having proved necessary. The line is a good piece of construction work on substantial wooden poles placed 100ft. apart. The wires on the upper cross-arm are of No. 0 bare copper, and form the original three-phase circuit designed for the transmission. The wires on the lower cross-arm are No. 0000 insulated wire, and are four in number. They were originally intended for a railway circuit, the generators for which were to be installed at Baltic to feed the Norwich street railway, but as the amount of copper necessary to do the work successfully appeared too great, the system was changed, a second three-phase generator and motor were added, and three of the four proposed feeder-wires were utilised for the three-phase circuit. All are supported on standard oil insulators, the fourth, No. 0000 wire, forming a convenient relay in case of accident to any of the others. At Taftville the three-phase circuits are led into the basement of the new mill, where they drive two three-phase synchronous self-starting motors, identical in size with the generators at Baltic. These motors are belted to the jack shafting previously driven by the engine, the pulleys on the shaft being equipped with friction clutches, so that the load can be thrown from engine to motor, or back again, without any interruption of service. The motors start entirely unaided, coming up to synchronous speed in about 50 seconds from the time the current is thrown on. They are, like the generators, separately excited, the exciters being driven from the pulleys on the end of the motor shaft.

The efficiency of the complete transmission at full load from the power applied to the dynamo pulley to that delivered to the motor pulley is just 80 per cent. In originally starting the mill before the second motor was ready for operation, it was the custom to bring the motor up to speed, and then gradually throw in the clutch connecting it to the shafting already running from one of the engines. When the clutch was fully in and engine and motor running together, the engine was disconnected by its clutch and the power transferred entirely to the motor. This could be done without producing the slightest disturbance in the speed, and in the same way, now that both motors are in and the engines shut down, the load can be shifted from one motor to the other if desirable. Ordinarily, however, there is work enough for both, when driving the 1,700 looms in the new mill, operating the lighting plant and the three 80-h.p. General Electric railway generators, installed in another part of the basement.

THE ELECTRICITY USERS' ASSOCIATION.

The objects of the association are as follows :

1. To provide members and the public generally with expert advice on all matters connected with the use of electricity.

2. To protect the interests of intending users, whether members or not, by supervising the erection and maintenance of all electrical apparatus they propose to use.

3. To protect the interests of users by periodically inspecting all the electrical apparatus, etc., installed, thereby minimising the cost of maintenance and the possibilities of inconvenience in the future.

4. To protect the interests of those who are served by a supply company or from a central station against inaccuracies in their charges by periodically testing the meters.

5. To protect users from losses due to leakage or other drawbacks.

6. To provide users of electricity with every facility for using their apparatus to the best advantage and with the utmost economy, especially as regards boilers, engines, and accumulators, all of which are sources of considerable waste and unnecessary trouble and expense unless they are thoroughly and periodically examined.

The members of the association participate in all the above advantages together with :

1. The annual inspection of their electrical installation free of charge, provided that the number of lamps does not exceed 100. Beyond that number special arrangements can be entered into. Inspections are made annually, the first being usually carried out immediately the work is completed. After each inspection a written report, drawn up by the engineers to the association, is forwarded by the secretary. These inspections are particularly valuable, enabling the member to judge from the first report whether the work has been properly carried out ; subsequent reports would show whether the installation is still in perfect working order or deteriorating.

2. The association will undertake to keep the installation belonging to a member in working order, exclusive, of course, of lamp renewals, and do all the necessary repairs free of charge for a period of 12 months, provided the association is allowed to draw up the specification and supervise the carrying out of the work. The rate for such work is usually 5 per cent. on the total cost of the installation, but special charges, other than those set forth in the accompanying schedule, may be obtained from the secretary. Under this arrangement, the member is enabled to obtain tenders based upon the same standard from several firms, obviously to obtain similarity in the details of the tenders, without which a fair comparison cannot be obtained ; a further advantage being that the member is relieved from any expense (for the usual extras) beyond that specified in the original estimate. By this means the best return for the money expended is ensured, together with the satisfaction of having competent supervision.

3. A member may at any time have a further inspection made should he desire it on payment of a fee to be arranged.

4. Should a member who obtains his supply from any public source consider that for any reason he is not being properly charged, the association will enquire into the circumstances and report to the member. The fee for testing a meter is £1. 1s., unless further examination be necessary.

5. The association is prepared to act as surveyors of risks in which electricity is used for the fire insurance companies, and also to make periodical inspections during such time as the risk remains on the books of the company. Such inspections are very necessary, as in the course of years experience shows that the original number of lamps is increased, and the mains becoming overloaded, heating is liable to ensue. Fuses are also replaced by inexperienced persons, and in many cases it has been found that copper wire of as large a sectional area as the main itself has replaced the fusible wire, thus rendering the cut-out not only useless but a positive source of danger. Special rates are quoted for such work, which may be obtained on application to the secretary.

6. The association is also prepared to advise on any matters connected with the use of electricity. The association does not execute repairs, but reports the nature and extent of the repairs necessary and supervises their execution if required. The saving effected by having alterations and repairs executed under such supervision is a much larger amount than is generally realised. Where practicable, the contractor who has carried out the work is asked to do the necessary repairs.

Rules of the Association.

1. The association shall be called the Electricity Users' Association.

2. The offices of the association shall be at such place as the council may determine from time to time.

3. The association shall be constituted as follows: president, vice-presidents, general council, and ordinary members.

4. The objects of the association are as follows: (*a*) To promote and protect the interests of users and intending users of electricity in the United Kingdom. (*b*) To take

Digitized by Google

such steps as the council may consider advisable to oppose fiscal or other legislation likely to be injurious to members, or restrict the application of electricity. (*c*) To provide members with expert advice on electrical matters generally.

5. A subscription of not less than one guinea per annum shall constitute membership of the association.

6. Any moneys received as annual subscriptions from members shall be applied to the payment of the expenses incidental to the general management and conduct of the association, and for the purpose of legal proceedings and other matters which may be deemed desirable to advance the interests of the undertaking. No liability shall attach to any member of the association beyond the amount of his subscription, and for this reason the association is being incorporated under the Companies' Acts. All receipts for subscriptions or other payments to the association shall be given only on the form specially prepared for the purpose and signed by the secretary, and particulars thereof shall be duly entered in the counterfoil. Every member on the payment of his subscription shall receive a copy of these rules.

The council may promote the formation of local branches of the association in all districts where such branches are likely to assist in securing the objects of the present association, or extending its influence and utility. The rules and by-laws of all such branches shall be approved by the council, and, subject to this provision, the members of such branch societies shall participate in all the advantages enjoyed by members of the parent association.

At the annual general meeting, the president and vice-presidents for the ensuing year shall be elected, who shall have the control and direction of the affairs of the society, as provided above. The council shall be summoned from time to time, as occasion may require, by the secretary. The notice of such meeting shall state the nature of the business for consideration. The president at all meetings shall have a casting vote. Three members of the council shall form a quorum.

In case of any dispute arising between any member and the association in relation to or in connection with the business of the association, the whole matter in dispute shall be referred to the president for the time being, whose decision shall be final.

Schedule of Charges—Engineering Department.

Particulars.	Current supplied from central station.	Users' own generating plant.
Examination of premises, preparation of specification and report thereon, and supervising installation during construction—		
Installation not exceeding 50 lights...	8 %	On amount of estimated cost.
50 and ,, 150 ,, ...	7 %	
150 and ,, 300 ,, ...	6 %	
300 and upwards	5 %	
Minimum charge	£2 2 0	... £4 4 0
Examination and report only upon specification submitted—		
Private houses, shops, etc.	1 1 0	... 1 11 6
Mills, factories, public buildings, etc.	2 2 0	... 3 3 0
Testing, examining, and reporting upon installations upon completion of contracts—		
Installation not exceeding 50 lights ...	1 11 6	... 2 12 6
50 and ,, ,, 150 ,, ...	2 2 0	... 3 3 0
150 and ,, ,, 300 ,, ...	2 12 6	... 3 13 6
300 and upwards	1% on contract.	

In addition to above, the association, as consulting engineers, are prepared to advise upon all matters connected with electrical work, and also to act as arbitrators upon questions of contract or other matters in dispute.

The following electrical engineers agree in the movement which has been inaugurated by this association: Messrs. W. P. D'Alton, London Electric Supply Corporation; Sydney T. Dobson, St. James's and Pall Mall Electric Light Company; R. C. Jackson, Newcastle-on-Tyne Electric Supply Company; Arthur Wright, Brighton Corporation Electricity Works; A. F. Barnard, Lancaster Corporation; J. T. Baron, St. Pancras Electricity Works; S. W. Baynes, Bradford Corporation; H. C. Buchanan, Weybridge Electric Supply Company; H. W. Cousens, Taunton Corporation; J. E. Edgcome, Kingston Corporation; F. Harman Lewis, Wolverhampton Corporation; A. H. Gebbings, Hull Corporation; W. E. Heenan, Northampton Electric Light Company, Limited; J. Hesketh, Blackpool Electric Light Company, Limited; W. D. Hunter, Newcastle and District Electric Light Company; J. A. Jeckyll, South Shields Corporation; W. Johnson, Sheffield Electric Light and Power Company; J. H. McLean, Oxford Electric Company, Limited; G. F. Metzger, Bath Electric Lighting Company, Limited; A. B. Mountain, Huddersfield Corporation; H. D. Munro, Exeter Electric Light Company; S. W. Newington, Oldham Corporation; G. W. Partridge, London Electric Supply Corporation; W. H. Patchell, Charing Cross and Strand Electric Supply Company; G. S. Peck, Scarborough Electric Light Company, Limited; H. Faraday Proctor, Bristol Corporation; G. Schultz, Notting Hill Electric Light Company; J. E. Stewart, Derby Corporation; H. Talbot, Nottingham Corporation; H. Tonge, National Electric Supply Company, Preston; F. F. Yeatman, Reading Electric Supply Company, Limited.

The solicitors to the association are Messrs. Windybank, Samuel, and Behrend, 35, Bucklersbury, E.C.; Mr. Charles H. Campbell, of 68, Victoria-street, S.W., is secretary (*pro tem.*); and the engineers are Messrs. Wilson and Clirehugh, of 3, Princes-mansions, London, S.W., and Temple-chambers, Brazenose-street, Manchester.

REVIEWS.

Electrical Measurements, and other Advanced Primers of Electricity. By Prof. E. J. Houston, A.M. The W. J. Johnston Company, New York; Whittaker and Co., London.

Electricity and Magnetism: being a Series of Advanced Primers of Electricity. By Prof. E. J. Houston, A.M. The W. J. Johnston Company, New York; Whittaker and Co., London.

Electric Transmission of Intelligence, and other Advanced Primers of Electricity. By Prof. E. J. Houston, A.M. The W. J. Johnston Company, New York; Whittaker and Co., London.

Prof. Houston has done good work in issuing these primers. He does not fall into the error of writing an advanced text-book and calling it a primer, but these papers are what they profess to be—full of instruction for that numerous class that desires to know the broad principles, to be able to utilise them in practice, and who do not desire to split hairs about the borderland of the subject. Prof. Houston, too, possesses the great advantage of having had considerable teaching experience, so that he knows what to say and what to leave unsaid. These excellent books should become as popular on this side the Atlantic as on the other.

Continuous-Current Dynamos and Motors. By Frank P. Cox, B.S. The W. J. Johnston Company, New York; Whittaker and Co., London.

We noticed the issue of this book in our number of November 3 last year, and have now merely to record it as having an English publisher. There is no doubt but that Mr. Cox has given a large amount of valuable matter, particularly intended to the younger students, in this volume.

The Popular Handbook of Finance. By A. Baines. Published by Saxon and Co., Bouverie-street. Price 1s.

In these days of limited companies and co-operative stores, when everybody who has a shilling to invest does invest it and does not follow the old-fashioned plan of keeping a snug sum of various coins in an old stocking hidden up the chimney, a book of the excellence of the one before us is certain of a wide approval. The information it contains is what everybody usually wants and is just as usually unable to find. To business men, and especially to those who have not been educated in a bank or a counting-house, the book will be invaluable. It will no doubt be looked upon as a book of general reference, as the price, being only a shilling, should ensure a very large sale. We cannot say that it contains anything electrical, except indirectly it tells us a good deal about limited liability, banks, bills, and so on; and if company work is not interesting to electrical shareholders it ought to be, seeing how great a part of the trade is carried on by such companies.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

BLUFFING AND HEDGING.

The letter of Sir John Pender to Sir Charles Tupper, which appeared in the *Times* of Wednesday, is exactly what we expected of the man. One paragraph carries out to the full our prognostications of some years back. At that time we suggested Sir J. Pender and his colleagues would exert themselves in every possible way to stop the Pacific cable. We at the time gave extracts from correspondence with their agents "down under" and others to show the methods adopted of educating the Press and public opinion to their views. At the same time we said that if the Pacific cable was inevitable, and their opposition failed to stop it, they would try to move heaven and earth to get it under their own control. This is exactly what is coming to pass, but the opposition has delayed matters till even for strategic purposes a new decision will have to be taken. France has stepped in while Englishmen have been squabbling, and if the Pacific cable is laid, it will either be to connect with the French or entirely independent. Which? is the question that has to be decided. Once more we reiterate the fact—and we in this case know exactly how far we may venture to speak—that the aim of Sir J. Pender and his friends has never had but one object—neither philanthropic nor patriotic, but immediately and intensely selfish. From first to last Governments have been played off against each other, both as regards mother Governments and colonial Governments, in order to consolidate and confirm a monopoly. Far be it from us to condemn this action from a purely business point of view. The greatest credit is to be given to Sir J. Pender and his colleagues for having so long kept competition at bay. If it were not for the one thing, that, in our opinion, they have never catered for their shareholders, but only for themselves, we could have no word against this policy from that particular point of view. It is, however, our firm belief that Sir J. Pender and his friends have enough of human nature in their constitutions to know that if they consistently pay five or six per cent., their management will not be too closely scrutinised. They will bluff or they will hedge, whichever suits their purpose. Now, we contend that from an Imperial point of view their system is vulnerable at every point. The late Sir James Anderson contended otherwise. He argued that loops along the coast from port to port were more easily maintained and repaired in troublous times than long lengths of deep-sea cable, and he was right, with an "if" given in. We insist that both ends of the cable must, for strategic purposes, be in the hands of ourselves or our friends, and not one end in our own hands while the other is possibly in the hands of our enemy, or with a sympathiser with the enemy. We quite agree with the difficulty of keeping intact a deep-sea cable against a powerful enemy determined to destroy it. Possibly our conclusions are wrong, but it seems to us that the greatest value of a cable under our own control would be in the early days of a conflict—just before and just after the final rupture. Given such a cable, every point of our empire would be prepared for hostilities, and though the destruction of a cable

Digitized by Google

after might be very inconvenient, it would have enabled the authorities to give warnings. If, however, there is no cable so controlled, these warnings would probably be impossible, or would be as well known to enemies as to friends. Sir John Pender's latest move is as 'cute as his moves usually are. It is to attempt to underbid possible rivals. We extract that particular paragraph of his letter to which we refer. It is as follows:

"If, however, the Governments concerned consider a second cable is required for strategic purposes—which I very much doubt—they must, of course, pay for it, and, as I have frequently stated, my company would be quite prepared to undertake the work on fair and reasonable terms, which terms would necessarily be more favourable to the Governments than could be obtained from any other company, owing to the exceptional facilities possessed by the existing system."

Probably, however, the voice of the charmer will, like the voices of the syrens in the olden legend, fall upon ears stuffed with materials to keep out the seducing vocal effort. At any rate, our view of the case is to have nothing to do with Sir J. Pender or any company with which he is directly or indirectly connected. If the matter falls under his control, depend upon it he will so fashion matters as to remain master of the situation.

THE ELECTRICITY USERS' ASSOCIATION.

Not many years ago sanitary engineering was in the happy-go-lucky position of being able to "go as you please." Drains were laid or not laid with a beginning and no end, or an end and no beginning. Nothing seemed very particular, and the result was usually typhoid fever. Suddenly, men began to agitate, and found out that bad drainage was, to say the least of it, unpleasant. Sanitary engineers, following Shakespeare's advice, and taking the frightened community "at the flood," managed "to lead on" to their individual fortunes. If we recollect rightly, an association was formed so that the householder paying a small amount could have his drains thoroughly examined and certified, and by the payment of a small annual amount could have them periodically examined. We do not know whether this action of the sanitary engineers gave the idea to electrical engineers to promote the association the title of which is given above, but the objects of the two associations are somewhat similar. The Electricity Users' Association professes to do for the users of electricity what the sanitary engineers profess to do for the householder—namely, to test apparatus and advise upon technical questions. The proposed association must be viewed from two standpoints: (1) the real views of the originators, (2) whether the public will obtain value for its money.

It is clear that the promoters of this association have had in their minds the obtaining of business by legitimate means—that is, while not acting unprofessionally, increasing their *clientèle* and giving full value for money. No doubt some critics will say the whole proceeding is unprofessional. We do not agree with this view, although, as is well known, we have strong opinions about the more extended use of the consulting engineer. But there are engineers and engineers, and we do not deem it unprofessional for an electrical engineer to become the consulting engineer to a company whose object is not only ostensibly, but really, to benefit the public. If the association is but moderately successful, the first result of its action will be to condemn a good deal of jerry wiring. The general public has yet to realise there are two ways of installing the electric light in houses—one (multitudinous) cheap and nasty, the other good and creditable to the installers. Unfortunately, too often the question of five pounds cheaper decides between a firm which has no reputation and one which has, and not in favour of the latter. Now, an association such as is proposed should be utterly independent of this firm or that firm, and should have one standard for all. We can quite understand that periodic inspection, if the recommendations made are duly carried out, will lead to a greater saving than the cost of inspection and alteration. Without going into detail, it is easily seen that slight leakages, meters out of repair, and such like things, may add largely to the bill, but not to the light. In fact, a concrete example will show that it may be greatly to the advantage of the user to pay his guinea and have advice. The other evening, while in the *foyer* of a theatre, a gentleman who used the electric light from the House-to-House Company's supply—Kensington way, was commenting upon the greater length of his bill during one quarter over that of the previous quarter, although he maintained that only the same number of lamps were used, and had been in use, he contended, a less number of hours during the quarter in which his bill was heaviest. Had the increase been small it would probably have passed unnoticed, but it was not small. Ordinary consulting work can hardly be said to touch such matters as this, and the field may well be filled by an association of the kind proposed. The promoters, as we say, hope to increase their business. In discussing one point we have necessarily trespassed upon the other point, and properly worked the public undoubtedly ought to get full value for its money. We have elsewhere given the full text of the objects and rules of the association with the schedule of charges. No doubt the rules will have to be varied, and the schedule of charges will not pass unchallenged, but these matters do not concern us at present. The important question in the first place is to ascertain whether the principle is to be adopted.

ELECTRICITY IN HEAVY RAILROAD SERVICE.

We have received a copy of a paper on the conditions of use of electric motors on the present steam railroads, read by Mr. D. L. Barnes at a recent meeting of the Western Railroad Club. Awaiting the preparation of engravings for use in extended abstracts from the paper, we give a short synopsis of the principal points.

Mr. Barnes first discusses the question of direct current

Digitized by Google

and plain motors and alternating currents and multiphase motors. He says that it is the hope of electricians that multiphase motors may become more practical than at present, for they have some advantages over the plain current motor, the principal one being simplicity of construction. But the alternating-current motor is not yet developed to such a point as will permit safe conclusions as to its final adaptability to railroad work, though it is probable that it will eventually be used for long-distance high-speed work. For the present, however, the plain current motor is useful, but the limit of its use for railroad work is found not so much in the motor itself or kind of current as in other matters.

The electric motor is, as compared with the steam locomotive, a simple machine, and the repairs must be correspondingly small. It has no valves to leak, boiler to get clogged with scale, firebox sheets to crack, grates to burn out, screw stays to break, crown sheets to come down, and so on through the list of annoyances to which the steam locomotive is subject. Therefore one great reason why electric motors may eventually take the place of steam locomotives will be found in the simplicity of construction, operation, and repair.

There are yet, however, serious problems to solve. One of these is that of collecting the current from the conductor. This is solved for low speeds, but for 60 miles an hour and upward it is still in question. However, there will probably be no great difficulty in arranging this matter. Another question is that of connecting the armature and axle. For the present, electricians generally have settled down to the use of gears, although motors like that on the Liverpool Overhead have been designed in which the armature shaft is the axle of the driving wheels. Electricians are still working on the problem of getting a variable connection between a revolving armature and a driving axle.

A careful analysis is made of the efficiency of plain current motors with positive connection, but this analysis cannot be intelligibly reproduced without the diagrams. It may be said, however, that the locomotives of elevated or suburban roads are constantly putting energy into a train up to the point of application of brakes, when it is immediately taken out by the brake shoes and wasted. It has been proposed to reconvert this energy into electricity during the process of braking by using the motors as dynamos, but no practical plan for doing this has yet been devised. It appears, however, from the investigation that for this kind of work the electric motor is best adapted to give good commercial results. The efficiency of the conducting line from the central station to the motors ought to be 90 per cent., that of the dynamos ought to be such as to give at their terminals a current that would represent 85 per cent. of the indicated power of the steam-engines, and the steam-engines ought to give 1 h.p. with 15lb. of steam an hour. Using the same sort of fuel on the steam locomotive as is used under the stationary boilers, and assuming it to be fair bituminous coal, each pound should evaporate into steam about 6lb. of water in the locomotive, or 8½lb. in a good stationary boiler, and the steam locomotive will generate 1 h.p. for about 25lb. of steam an hour when the locomotive is of the best type. On this basis, comparing the indicated power in the steam-cylinders of both systems, we have 1·8lb. of coal per horse-power per hour in the stationary engine, and 4·2lb. of coal per horse-power per hour in the steam locomotive. But the steam locomotive uses the power directly, and there is no further loss that has to be considered in the comparison. With the electric system there is a further loss of 15 per cent. in the dynamo and connections, 10 per cent. in the line, and 50 per cent. in the motors for switching suburban and elevated railroad work, or 20 per cent. in the motors for lines having about eight minutes between stations. The final result is the delivery of about 30 per cent. of the efficiency in the cylinders of the stationary engine, at the drawbar of the motor, for switching, suburban and elevated railroad work and 61 per cent. for the longer line assumed. The result figures out, then, 4·7lb. of coal an hour in the stationary engine for one useful horse-power delivered at the drawbar of the electric motor for short lines, which is practically the same as that required for the steam locomotive; for the longer line assumed the fuel consumption would be 3lb. an hour per useful horse-power. This is based on ordinary fuel. With anthracite burned on large grates the locomotive will do better work in proportion, and the difference in economy of fuel will be in favour of the steam locomotive on the short lines.

In elevated railroad work, using anthracite coal and compound locomotives, we may take 3½lb. of coal per horse-power per hour at the drawbar. Hence, considering only the use of fuel in actual work, there would be no saving in the weight of fuel by using electricity.

The conditions vary so much that each case must be treated by itself, but for practical comparison we may assume that the same weight of fuel per ton-mile would be used with the electric system as with the steam locomotives for short lines. If the conditions are such that a cheaper kind of fuel can be used at the central station than on the steam locomotive, there may be a considerable saving in cost of fuel, while there is none in the weight. In short, the conditions which regulate the price control almost entirely the saving in fuel cost incident to the use of electric motors. For long runs also it appears that the average conditions are such that the same weight of fuel would be used per ton-mile, and it is only where a higher priced fuel is required for the steam locomotive than for the central station that any substantial saving in fuel cost could be made.

The first cost of central-station plants and conductors for long-line work is so great per mile of track that the companies must for the present hesitate to make the experiment of changing, and prices are so unsettled that it would be valueless to attempt any estimate of the cost of changing a large steam locomotive plant to an electric one; but it would not be surprising if a year hence the cost of installing an electric plant for long-distance work would be half what it was a year ago. Only on short lines where the traffic is crowded is it now economical to substitute electric motors for steam locomotives.—*Railroad Gazette.*

DYNAMO PATENTS IN CONNECTION WITH NIAGARA.

Three patents were issued on the 1st inst. by the United States Patent Office to Prof. George Forbes, which are said to embody some of the principal features of the 5,000-h.p. dynamos about to be installed at Niagara, and which were discussed in Prof. Forbes's paper read before the Institution of Electrical Engineers.

One of the patents, according to the *Electrical Engineer* of New York, describes very clearly the objects which had to be attained. The first object was a possibility of winding the machine to get a high E.M.F. as safely in the machine itself as in a step-up transformer. This can be done in a large machine of 5,000 h.p., where the space occupied by insulation need not bear the same proportion to the space occupied by wire as in a smaller machine, and where oil circulation can be employed. It can be accomplished by having the armature stationary, especially if the shaft be vertical. The position has been taken up by Prof. Forbes that it is possible to do away with the cost and losses in a step-up transformer, that the large stationary armature is as safe to wind as is the step-up transformer, and if the difficulty of using very high electric pressures in the dynamos be shirked it must be faced in the transformer.

The next three objects were all attained by one simple expedient. These were (1) to get mechanical security having in mind the enormous centrifugal forces at a speed of 250 revolutions a minute, (2) to have a maximum of flywheel momentum with a minimum of weight, and (3) to prevent the magnetic pull from assisting centrifugal force to rupture the revolving part. These were all attained by the simple expedient of making the revolving fields external to the armature.

It is said that every one of the designs submitted to the Cataract Company had a separate flywheel, which increased the weight to be supported by the hydraulic piston in the turbine beyond what it was capable of supporting. In all

Digitized by Google

the designs the magnetic pull between the field poles and the armatures helped centrifugal force to break the revolving part, and in those with revolving fields the field coils were held in by pole faces held in place by bolts and keys—a source of weakness considering the high centrifugal forces.

Owing to the great diameter of the revolving part there is a maximum momentum with minimum weight, and all need for a flywheel is done away with. When the load is removed, and while the turbine governor is cutting off the water, this enormous momentum prevents the machine from varying its speed unduly. Moreover, the magnetic pull between the pole-pieces and armature diminishes very appreciably the tendency of the centrifugal force to break the flywheel; while the pole-pieces and their coils are all held securely by the centrifugal force against the interior of the ring which forms at once the flywheel for the turbine governor and the yoke for the field magnets. Further, the central armature, being fixed, can be wound for very high electric pressures.

Of the two other patents issued at the same time to Prof. Forbes, one refers to the notching of the armature to hold two types of coils which overlap each other; and the other a method of enclosing the armature coils with an envelope and circulating oil through the coils, to carry off the heat and to provide for high insulation.

THE GLASGOW CORPORATION ELECTRIC LIGHT STATION.

Pressure on our space has hitherto prevented us from dealing with the paper read by Mr. Wm. Arnot, A.M.I.C.E., before the Institution of Engineers and Shipbuilders in Scotland on "The Corporation Electric Light Supply." We, however, now append the following abstract of the paper and discussion thereon.

The provisional order obtained August 14, 1890, gave the Corporation two years to carry into effect the powers granted therein. Lord Kelvin was consulted October 9, 1891, and his advice was most decided on the advisability of supplying with a direct current at not more than 200 volts. It having been decided to adopt a low-tension three-wire system, Prof. A. B. W. Kennedy, F.R.S., was requested on November 12, 1891, to prepare a scheme. A site was obtained in Waterloo-street, at the corner of Mains-street, and the contract for the building was signed on April 7, 1892. On Saturday, February 25, 1893, the arc lamps on the principal streets were first lighted, and the current was switched on to the incandescent mains on Saturday, April 22, 1893.

My paper on this subject would be incomplete without reference to the work carried out by Messrs. Muir, Mavor, and Coulson, Limited, previous to that date. Of the commencement and details of their work it is not necessary for me to trouble you. Suffice it to say that on March 1, 1892, the Corporation purchased the plant of that company, which was then supplying from John-street an alternating current at 2,400 volts on the mains. These mains were all overhead, and the lamps were supplied at 100 volts, the pressure being reduced by means of a transformer in each consumer's premises. On the date of the purchase there were 36 consumers, taking current equivalent to the supply of 5,000 8-c.p. 33-watt lamps. The Board of Trade granted permission to the Corporation to continue the use of these mains on the condition that they should all be removed by August, 1893. To transfer the customers from the high-tension overhead mains to the low-tension underground mains was the first duty of the staff. This was done at the rate of about three per day, and John-street station was shut down on May 11, 1893. The site at Waterloo-street station measures about 31 yards by 31, and contains 972 square yards, having Waterloo-street to the north, Mains-street to the west, and Wellington-lane to the south, and a tenement of offices on the east side. The building stands on a layer of concrete 2ft. thick, laid throughout the entire block. The main building stands fronting Waterloo-street, and covers half of the ground. It consists of the engine-room, first floor with offices and workshop, and second floor with laboratory, drawing office, meter-room, and cable floor. Behind the main building is the boiler-house, with the battery-room above it.

Boilers.—These consist of six marine-type steel boilers, measuring 12ft. long and 10ft. in diameter, working at a pressure of 160lb. They have each two furnaces of the corrugated type, with an internal diameter of 3ft. The fire-grates are 5ft. long. There are 194 wrought-iron lap-welded tubes in each, 2¾in. external diameter and 8ft. 6in. long, between the tube plates ⅛in. thick, stay tubes ¼in. thick. A steel steam-drum, 5ft. long by 18in. diameter, is on each, with two 5in. stop-valves. The mountings are very complete, being two safety-valves, two automatic water-gauges with plate-glass guards, two shut-down feed-check valve, blow-off cock, scum cock, 12in. diameter steam-pressure gauge, attachment for test pump, attachment for engine indicator. These boilers were all tested and passed by the Board of Trade inspector. A smoke-box is on the front of each boiler connecting the tubes to an uptake which communicates with the main flue. This is led into the chimney at a height of 15ft. There are no underground flues. Each boiler is covered with 2½in. composition, and stands on two cast-iron brackets. There are two Tangyes (steam 7in., water 4½in.) pumps, each capable of delivering 4,800 gallons per hour, either through a Wright's feed heater or direct. There is an injector connected to the cold feed capable of delivering 5,000 gallons per hour. The water-tank has a capacity of 3,500 gallons. The steam-pipes are 7in. and 8in. diameter, steel, lap welded, with wrought-iron flanges screwed and brazed. In the engine-room the steam-main forms a complete ring, slung by means of rods from cast-iron brackets. Four of the boilers have a duplicate connection to this ring, the remaining two have one connection.

Engines.—These are Willans central-valve compound engines, of the following particulars: Two size G G.—Number of cranks, two; diameter of low-pressure cylinder, 14in.; high-pressure, 10in.; stroke, 6in.; revolutions per minute, 450; i.h.p., 78. Two H H S.—Number of cranks, two; low-pressure cylinder, 17in.; high-pressure, 12in.; stroke, 8in.; revolutions, 370; i.h.p., 160. Three I I S.—Cranks, two; low-pressure, 20in.; high-pressure, 14in.; stroke, 9in.; revolutions, 325; i.h.p., 222. Two I I I S.—Cranks, three; low-pressure, 20in.; high-pressure, 14in.; stroke, 9in.; revolutions, 350; i.h.p., 360; steam pressure 150lb.; the cranks of the duplex engines are set opposite at 180deg., the triple at 120deg. The engines are single acting, with a receiver between the high pressure and low pressure. The valve-rod eccentric is placed in the centre of the crank. There are two connecting rods, one on either side of the valve rod. The piston rod is hollow and contains the steam-ports. The valve rod works in the centre of the piston rod. The cross-head is contained in a trunk piston, which act solely as a guide, and by means of which the pistons are cushioned on the up stroke. Air is admitted above this piston by the ports on the guide cylinder; this is compressed and expanded again on the stroke.

Dynamos.—The dynamos are two-pole shunt-wound, with drum armatures. They are coupled direct to the engines, with a heavy disc to ensure steadiness in the running. The combined plant stands on one sole-plate. The maximum output of the several dynamos is: two 330 amperes, 140 volts, 92,400 watts; two 400 amperes, 230 volts, 184,000 watts; three 670 amperes, 230 volts, 462,300 watts; two 980 amperes, 230 volts, 451,200 watts; making a total of 1,189,900, or 1,190 units. The absolute necessity of working without making any smoke has led to the use of gas coke, obtained from the Corporation gasworks. At a preliminary trial on one boiler, in April, 1893, when working with a very light load, the water evaporated was 27,458lb. in eight hours; 3,770lb. of coke were used. Mean boiler pressure, 149; mean feed temperature, 145deg.; evaporation per hour, 3,432lb.; actual evaporation per pound of coke, 7·28; reduced to standard, 8·13. The value of this per unit generated was ·24. The analysis of the coke showed: moisture, 10·68; ash, 10·16; loss on ignition, 79·16. Assuming this to be carbon, it gives 11,416 thermal units per pound. The result of measurement in a calorimeter gave 11,286. It may therefore be taken that the evapora

Digitized by Google

tive value of this coke is 11·75lb. of water under standard conditions. These figures do not take account of the coke used at night when no work is being done. The trial only lasted for eight hours. An extended test was made by Prof. Kennedy on November 2 and 3, when the following results were obtained:

Total duration of experiments ..... hours	48
,, coke put on fires ..... lb.	61,900
,, coke used in boilers of which the stop-valves were closed ..... lb.	9,260
,, net coke used for steam ..... ,,	52,640
,, water through meter, allowing for all differences of level ..... lb.	378,970
,, water used while station was shut down ..... ,,	16,296
,, net water used during running hours ..... ,,	361,674
,, electrical work at dynamo terminal ...e.h.p. hours	8,991
Total electrical work at Board of Trade units, or kilo-watt-hours	6,708
Pounds of water evaporated per pound of coke put in fire, actual	6·12
Pounds of water evaporated per pound of coke put in fire, reduced to standard	7·38
Pounds of water evaporated per pound of net coke, actual	6·87
Pounds of water evaporated per pound of net coke, reduced to standard	7·91
Ratio of stand-by fuel to total fuel on fires, per cent.	14·96
Pounds of water used per unit generated	56·5
,, ,, ,, net water only	53·93
,, ,, per e.h.p. hour	42·14
,, ,, ,, net water only	40·2
Pounds of coke put on fires per unit generated	9·23
,, net coke used	7·85
,, coke put on fires per e.h.p. hour	6·88
,, net coke used	5 85
Total running hours during the two days	33·75
Mean load during running time ..... kilowatts	198·7
Maximum load ..... ,,	669·4
Ratio of mean to maximum load ..... per cent.	29·7
Load-factor per actual hours and engines ..... ,,	68·4
Mean steam pressure, pounds per square inch above atmosphere	151 5

During two days' trial the total coke put on the fires was 61,900, but of this 9,260 was required to supply damped fires and condensation in the steam-pipes through the night. The main steam-pipe is always under steam for the sake of the joints. The ratio of 14·96 per cent. between these figures is rather high; the water consumption is much too high. These figures will be improved, faulty traps and drain cocks being responsible for much of the loss.

The engines and dynamos combined show an excellent efficiency. The efficiency curves were taken by Prof. Kennedy at Thames Ditton before delivery here. The curves for the last large set were thought to be too good to be correct, being 88 per cent. for the combined plant at full load, a loss of only 12 per cent. between the indicated horse-power on the engine and the electrical horse-power delivered at the terminals of the machine. Before accepting the results all the indicator springs were independently tested and found correct. The results were therefore accepted. The consumption of water per indicated horse-power was 17·5lb. for every horse-power added after 40 i.h.p., which is required to drive the engine and dynamo. These curves show that with an engine load-factor throughout the station of 50 per cent., or half load, an efficiency of 80 per cent. can be maintained in the generating plant.

Accumulators.—A set of accumulators is placed over the boiler-house. This position keeps them in a suitable temperature; otherwise during the winter they would be affected by frost. The set consists of 114 cells, 57 being placed between the negative wire and the middle, and 57 between the positive and middle. Each cell has 61 lead plates, with a capacity of 1,000 ampere-hours at two volts, with a discharge rate of 200. There are six cells as repair cells, or, as they are sometimes called, milkers. From these, plates are taken to replace faulty ones in the working set, and should a cell show any weakness it is not allowed to discharge for a day, but is short-circuited by two milkers in series. It has thus four volts across it. The battery regulating switches are placed in the battery-room, and controlled by bevelled gearing from the switchboard.

Distribution.—The distribution begins practically at the switchboard. It is generated at from 210 to 230 volts, and is kept constant at the feeding points at 205 or 102 on each side of the system. The balance is maintained in the station by means of two 100-volt machines. The difference in current between the two sides does not generally exceed 200 amperes at any load. Exceptional nights have been known, such as 650 amperes, when both machines had to be run on the one side. I have put before you curves showing one of the heaviest days, and one of last month, which shows a falling off. The load-factor for these days is noted on each. This factor is the ratio between the total output and the possible total output if the plant were working full load for 24 hours. I have also noted the ratio between the amperes of current applied for and the maximum output. In December it was 54·3, and February 37·1. The real efficiency of running is shown in the plant load-factor, which in February was 68·5 per cent. It has been as high as 71 per cent. This factor is the ratio between the output and the possible output if the machines were run full load from the time each one is started till stopped. This is the percentage that tells on the costs of running, fuel, water, oil, etc. The lamp connections have progressed in a fairly steady curve. October has the largest number of applications. The maximum output has not reached more than 54 per cent. of the total lamps wired.

The underground work in the streets is, I presume, pretty well known to you. The copper strip is laid on porcelain insulators in iron culverts, which are watertight. I do not mean that under a pressure they would keep out water, but owing to their construction, the lids overlapping the culverts, the ground in which they lie must be flooded before the water could rise high enough to enter through the seam. I have never known an instance of water in the culverts. Water does collect in the brick junction-boxes, especially in Bath street, and districts where we have heavy clay soil. Provision is made in all such for their thorough drainage. Where it is not possible to lay copper strip, indiarubber-covered cables have been laid in cast-iron pipes. In distributing by three wires a network of copper is laid down. There are, generally speaking, three wires on each side of the street; in some cases there are only two wires—positive and middle on one side, negative and middle on the other. Where strip is laid the positive is always next the building, and the negative always outside. Where cable, the positive is painted blue, middle white, and negative red. The entire network is connected together throughout the city, positive to positive, middle to middle, and negative to negative. The current to this network is conveyed by means of what are termed feeders; these are marked green on the map, and are so constructed on their sectional area as, when fully loaded, to give an equal drop in the potential. There are only two conductors to each feeder—one positive and one negative. The middle wire of the network, or distributing mains, as we call them, is brought back to the station from several points, and has a sectional area of 1in. at the station. The potential is maintained constant at the points where the feeders join the network; it is therefore necessary to raise and lower the potential at the station to compensate the rise and fall of the load. For this reason, no house connections are taken from the feeders. All are taken off the distributing mains. As a rule, only two wires are taken into each consumer, either from the positive and middle, or negative and middle. Every care is taken to balance the two sides—that is, to have as many lamps connected to the one side as the other. Not only in the number of lamps has this balance to be maintained, but also in the class of customer. Early shops must be balanced against early shops, and late against late, houses against houses, and clubs against clubs. Where a large quantity of current is required, we balance such a building in itself, and take three wires to the main switchboard, where the division is effected. The joints, which are perhaps the most important in the cable mains, are all vulcanised, thus making them equal to new cable. It may be interesting to you to learn that I have some of the indiarubber cable placed underground that was used by Messrs. Mavor and Coulson overhead, and purchased by them five years ago. It seems as good and tests as well as new cable. Faults in the underground mains are easily found by means of a compass needle. The needle is placed on the faulty conductor and brought to be parallel with it by means of a strong directing magnet. The other conductor is flashed to earth, and the direction of the excess current

Digitized by Google

due to the fault is noted. In this way it is easily traced. Nearly all the faults are caused by careless workmen. The last fault was in Renfield-street on the middle wire, and was traced in half an hour.

There are now 382 consumers, who have applied for a current of 15,487 amperes, which represents, roughly, 46,460 8-c.p. 33-watt lamps, distributed somewhat as follows:

	Shops.	Ware-houses.	Offices.	Churches.	Private houses.	Clubs, hotels, and theatres.
No.....	242	21	91	3	12	13
Amperes...	7,776	2,680	3,269	229	275	1,258

I have endeavoured to lay before you in as concise a form as possible a description of the works and plant in use at the Corporation electric lighting station. We have not had a year's run yet, and it is therefore impossible to give figures as to cost of production, etc. The author would take this opportunity of stating that the successful issue of the winter's labour has been due, in a very great measure, to the working staff. They have spared no pains nor trouble. The work has been their first consideration. From the highest to the lowest all have worked well.

Discussion.

The **President** said it was rather difficult to discuss this paper adequately, bristling as it was with figures, but he hoped that some of the electrical experts present would start the discussion. The mention of Prof. Kennedy's name as consulting engineer to the Corporation electric lighting reminded him that the University of Glasgow had seen fit to confer upon him the degree of Doctor of Laws. He was one of their honorary members, and he thought it showed the discrimination with which their honorary members were selected.

Mr. Mavor said that although he considered the system adopted by the Corporation unsuitable for the work to be accomplished, he wished to compliment Mr. Arnot on the successful starting of the Glasgow electrical station, and to say that, watching critically the result of their work, he could do nothing else than say that it had been so far successful, and that the Corporation were giving the public a thoroughly satisfactory supply of electricity. The company with which he had been associated had the honour of applying for a provisional order before the Glasgow Corporation did so. In doing so they worked out a scheme for the lighting of Glasgow which differed very materially from the one now being carried out. The principal difference was that they considered that in attacking the problem of lighting the city, they must look at it not so much from the immediate position as from the probable future requirements of such a city as Glasgow. Now, that was a very large and difficult problem, and in making up their minds on the subject they devoted much care to the question, and used as much as possible the experience which had hitherto been gained upon this point. He regretted to say that Lord Kelvin diametrically differed from them, although he was their consulting engineer, as to the advisability of using high-tension alternating currents. He would not attempt to discuss the reasons here, but he thought it was not difficult to see why the Glasgow Corporation were advised to adopt continuous currents in the circumstances in which they were placed. As Mr. Arnot had pointed out, the Corporation allowed a very large amount of the two years allowed by the Board of Trade to elapse before they took any steps in the matter at all, and it had to be admitted by the most ardent advocates of the alternating-current system that it was not then so well developed as the continuous-current systems for application to public lighting. A very large amount of work had been done by the Glasgow Corporation on a system almost precisely similar to that adopted in America by the Edison Illuminating Company. They had done an amount of work which was enormously greater than anything done in alternating currents, and the experience gained handicapped the alternating currents in the race, because they were later in coming on the field; but in these days he thought no one would venture to dispute that the high-tension alternating current was making its way forward, and that the engineers who had the necessary experience to enable them to compare it with the low-tension continuous currents thought that the day was not very far distant when no one would hesitate to use high-tension alternating currents in districts which were so eminently suited for such an application as the district which the Glasgow Corporation had undertaken to light. He thought it would be evident to all engineers present that there was something wrong when the Glasgow Corporation, having undertaken to light not only the compulsory area (which is really all they had been compelled to consider up to this time), but the whole Royal burgh of Glasgow, already in their first winter, had nine separate engines running in the station. Not only that, but the station, as at present constituted, could not be very much increased in size. The answer to that was that another one would be started, and that it was better not to have too many eggs in one basket. Various other reasons which had a certain amount of cogency were pleaded in excuse. There was a limit to the size of stations, it was true, but there was also a limit to the possibility of starting electrical factories all over a city like Glasgow, and it seemed reasonable to suppose that in lighting a city like Glasgow, they should look to the experience of gas distribution as a guide as to what they might do with electricity. He contended that there should be as many stations for electric lighting as gasworks at present, because the problem was the same. He hoped at next meeting to bring forward some considerations which might interest the institution with regard to some of the points Mr. Arnot had mentioned, especially with respect to the load curves and to the efficiency of the engines. These were very interesting points indeed, and, after all, were the centre of the matter. It would be evident to anyone who looked at those curves that to use steam-engines, or any other source of power, for the production of electric lighting was not an economical thing to do, and all that could be done, as Mr. Arnot had pointed out, was to run the engines at full load for only a very short period of their existence. The rest of the time they were standing idle and doing nothing. That was a kind of industry which was not a paying one, and therefore strenuous efforts had been made to find some means of storing the work of the engines so as to apply it to the circuit when the load curves reached that very high peak which occurred during the greater part of the winter, between 5 and 6 o'clock in the evening. The attempt to do that had been so far unsuccessful. The use of accumulators was indicated in that diagram by the blue lines, and they would see how very small a part they played in the operation of the station. It was totally insignificant as compared with the work done by the engines, and although they were useful in their way, he thought that on the whole the practice adopted in America would be followed in this country, and that batteries would not be used in lighting stations. There were some other points that he would beg respectfully to differ with Prof. Kennedy upon in his arrangement of the switchboard. It seemed to him that his arrangements of the switchboard were very complicated—it seemed to him partly owing to the use of batteries, which led to more complication than was warranted by their use in working. Perhaps Mr. Arnot would be good enough to say what was the maximum loss in the feeders. He mentioned that under certain circumstances it was 25 volts, or 12½ per cent., or thereby. Now that was another matter which meant a considerable amount of complication on the switchboard. If there was a loss of 12½ per cent. between the generating plant and the most distant part of the system, that loss had got to be compensated for in the engine-room, and as the loss varied with the load the compensation would vary, and that necessitated constant watchfulness on the part of the attendant, and was one of the reasons why the continuous system was more difficult to work than the alternating-current system. As to question of the relative cost of high and low tension systems, this was a battle which had yet to be fought out, and had to be won by one side or another. There were many cases where continuous currents had a superiority over alternating currents, but the case in question was, in his opinion, not one of these. The published figures of relative costs of lighting stations were interesting in this way—they proved that the first cost of an installation of continuous currents was greater than the first cost of alternating currents per lamp, but that the cost of working the continuous system was less than that of working the alternate-current system per unit, and in balancing these two it was very difficult indeed for the most ardent partisan of either system to find very much to say on the question of economy, so that the thing resolved itself into a matter of convenience; and, fortunately, nowadays there was plenty of opportunity for gaining the experience that would determine which was the more practically convenient. There was an element in this question which was specially interesting to Clyde engineers. Prof. Biles, in his paper recently read to this institution, pointed out that there was a possible limit to the size and speed of ocean steamers. It therefore might come to be a question whether the Clyde engineers might not take up the construction of large land engines on marine lines. This had already been done to some extent, and it might be interesting to Clyde engineers to know that experience showed that the use of alternating current tended to increase the size of the engines used. The Waterloo-street station was a very good object-lesson on this point. There were already nine engines in this station, producing a total horse-power of something under 2,000, whereas the speaker thought that it was not too much to expect that the lighting of a city like Glasgow would ultimately give employment to engines of such powers as 10,000 horse, rather than the small units now employed.

Prof. Jamieson said he hoped to discuss this paper at next meeting after it had been printed. Mr. Mavor had, however, brought forward a little of the history of this installation, and consequently it might not be out of place to say that he (Prof. Jamieson) was consulted by the Glasgow Corporation Electric Light Committee, and had many meetings with them before Lord Kelvin was called in and approved of the advice which he had given—viz., that under the peculiar circumstances in which they were placed (with a dense but limited compulsory area), and seeing that they had so little time to plan, erect, and equip a central station, they should go in for the safe and sure system which Mr. Arnot had described to them that evening. He did not agree with Mr. Mavor on many points, and especially that part where he said that they should have great big engines working at one big centre. He believed rather in using comparatively small engines, and consequently in being able to put in or take out power as the public demanded the same. He complimented the author for having brought his paper before their society, for the members evidently took a great interest in such matters, and it was likely to bring out a lively and useful discussion.

Mr. Biggart said they were all interested in such a paper as the one now read, but some were more interested from the point of view of that of the consumer than that of the producer, and he thought Mr. Arnot had not given much information with regard to the cost of electrical lighting as compared with that of gas;

Digitized by Google

Now, he believed there were many who would be consumers if they could see that the light could be supplied at a moderate rate. He had heard estimates outside of what the cost was as compared with the gas light, and some of these stated the gas was only one-third of the cost of the electrical light. Perhaps Mr. Arnot would be able to confirm or contradict that next evening.

SOLIDS, LIQUIDS, AND GASES.

At the Royal Institution, on Thursday of last week, Prof. Dewar gave the second lecture of his course on the "Solid and Liquid States of Matter." In his previous lecture he dealt with the changes of matter from liquid to gas, from gas to liquid, and from liquid to solid. He explained what was meant by the critical temperature of a liquid, and showed that no substance can be induced to remain in the liquid state if heated above its critical temperature. At the critical point, too, the volume of every liquid is at its maximum, while it is a minimum just when passing into the solid state, and the ratio between these two volumes is almost the same for all liquids—viz., 3 to 1. The transition from gas to liquid was illustrated by liquefying carbonic acid gas under pressure To make a substance pass from liquid to solid it is necessary to make it part with some of its heat. Solidification in some cases may be produced by rapidly evaporating the liquid under the air-pump, and in others by the application of great pressure. In general the heat must be increased if a substance is to remain liquid under pressure. Ice, however, melts under pressure, and by this fact the phenomenon of regelation can be explained. In his second lecture Prof. Dewar used ice to illustrate the changes which may be caused by pressure in the physical properties of substances. At ordinary pressure ice is a brittle substance, but under a pressure of 30 or 40 tons to the square inch it behaves like a viscous solid and may be forced through a narrow orifice in the form of a fine wire If, however, it were cooled to 20deg. below zero, an immensely greater pressure would be required to make it act in the same way. After describing his now well-known vacuum jackets, by the aid of which he can keep liquefied gases for many hours, the lecturer proceeded successively to liquefy and solidify common air in the presence of the audience. An empty test-tube open to the air was placed in liquid oxygen contained in a vacuum jacket. When the oxygen was evaporated under the air-pump, liquid air condensed in the inner tube. This tube was then also put under the air-pump, and in a few seconds the liquid air in it became solid, at a temperature of about 210deg. C. below zero—the lowest temperature yet reached. Some illustrations of the effects of extreme cold on bodies was then given. Several of the salts of mercury, such as the iodide and red oxide, which are red at ordinary temperatures, became yellow when cooled to −180deg., showing that the conditions of the absorption of light are greatly modified at low temperatures. At −180deg. only one compound gas refuses to solidify, and that is carbonic oxide, the most volatile compound known. At this temperature some substances freeze into a glassy ice, others into an opaque crystalline solid. Methyl alcohol or wood spirit and bisulphide of carbon are examples of the latter class, amyl alcohol, the chief constituent of potato spirit, and turpentine of the former. The vapour given off by liquid oxygen boiling at −180deg. is at that temperature, and is about three times as dense as ordinary air. In it very fragile bodies can be cooled, and the pretty experiment was shown of freezing a soap bubble in it. Extreme cold has a curious effect on indiarubber, which, when under tension, contracts on heating and expands on being cooled. In conclusion, the lecturer showed how to measure the quantity of heat taken in by a liquid on expanding. This is effected by introducing a known amount of heat (as can be done by dropping in a certain quantity of mercury) and measuring how much gas is distilled off. By a slight modification of the method the specific heat of the liquid may be calculated.

COLOUR VISION.

Captain Abney, F.R.S., gave his second lecture on colour vision at the Royal Institution on Saturday afternoon. He began by showing diagrams in explanation of the Young-Helmholtz theory of colour perception, which is the one perhaps most generally accepted at the present time. It supposes that for the normal eye there are three fundamental sensations—red, green, and violet. Any colour—except, perhaps, those at the very extremities of the spectrum—excites all these sensations, but in different degrees, the colour green, for instance, especially exciting the sensation green, though it also to some extent excites the red and violet sensations. White is the effect of the equal stimulation of the sensations. This theory Captain Abney considers is capable of explaining all cases of colour-blindness that are congenital and not the result of disease. About 5 per cent. of mankind are colour-blind—that is, are deficient in their perception of one of the fundamental sensations, most commonly red. Persons have been found, too, who are wanting in two of the sensations, and, therefore, have monochromatic vision. In such cases it is usually the violet sensation that remains, but Captain Abney has found one person who sees all things green, and would much like to meet one who sees only red. With a very small illumination—say, 1-100 of a candle-power, everyone has monochromatic vision, and this fact explains why colours are seen so badly by moonlight, which is a very feeble light. Besides being unable to perceive certain colours the colour-blind man is incapable of accurately estimating the brightnesses of colours. Thus, a man who is blind to red will affirm that a certain patch of white is as bright as a given patch of red, though to the normal eye it is manifestly less bright. Captain Abney concluded by showing that the eye is not equally sensitive to the different colour sensations. Thus, if the illumination of two patches of colour, the one dull green and the other bright red, be gradually diminished, the green will be visible for some time after the red has disappeared.

CANADA IN RELATION TO THE UNITY OF THE EMPIRE.

There was a large attendance at the ordinary monthly meeting of the Fellows of the Royal Colonial Institute at the Whitehall Rooms, Hôtel Métropole, on May 8, to hear the Canadian High Commissioner's interesting address on the above subject. The Marquis of Lorne occupied the chair.

Sir CHARLES TUPPER began his address by saying that the most important event of recent years conducive to the unity of the British Empire was the confederation of Canada. Another important event pointing in the same direction was now impending. A conference of representatives of the Governments of Australasia, of the Imperial Government, and possibly of the South African Governments, would be held at Ottawa in June for the purpose of considering the best means of drawing these great outlying possessions of the Crown into closer trade relations with each other and with Great Britain. A deputation of the representatives of Australasia, South Africa, and Canada recently had an interview with the Earl of Rosebery and the Marquis of Ripon on this subject. They stated that Canada had agreed to give a subsidy of £175,000 a year to a fast steamship service between England and Australasia *vid* Canada, and would give substantial support to a cable from Vancouver to Australia, and that these subsidies would be largely supplemented by the Governments of Australasia, and they asked for the co-operation and aid of her Majesty's Government to these services on the ground of their great political, strategical, commercial, and defensive value. This movement had received, as might naturally be expected, the hearty support of a large portion of the Press of this country. Many persons had been surprised to find that Sir John Colomb, who had professed to be a friend of the unity of the empire, had assumed a position of hostility to these proposals. He was apparently not well informed of the extent to which the great colonies had rendered yeoman service to the defence of the empire—unless, as he seemed to think, the term empire applied only to Great Britain. Who, with such evidence as the trade returns before them, could question from an Imperial standpoint the importance of developing the commerce between the colonies and between them and the mother country? The present intention of the proposed steamship company was to have upon the Atlantic a weekly service of 20-knot speed all the year round, and to maintain it by the building of four exceptionally large, swift, completely equipped, express passenger steamships. On the Pacific, at present, it was only proposed to have three steamships, thus adding one steamship to those now performing the monthly service between Sydney and Vancouver. At the Ottawa Conference one of the most important subjects for consideration would be whether the time had arrived for Great Britain and the Australasian Colonies to recognise Canada as an Imperial highway for an Australasian mail service, affording the empire an important alternative route; and he ventured to hope that a favourable decision would be arrived at. Sir John Colomb had asked who was to pay and to be responsible for the protection in war of the new trade line and new submarine cable we were asked to help to establish? There was the highest authority for the opinion that the naval strength provided by these fast steamers on the Atlantic and Pacific Oceans and the proposed cable from Vancouver to Australia formed the strongest claims to Imperial support. The contract entered into by the Government of Canada with Mr. James Huddart required the four Atlantic steamships to be capable of steaming 20 knots, under favourable conditions, at sea, and this would involve a trial trip speed of 21 knots, or equal to 24 statute

Digitized by Google

miles per hour. The steamships would be upwards of 10,000 tons register, and would be built in compliance with the usual conditions necessary to secure the subvention for mercantile armed cruisers from the British Admiralty. The Colonial Conference called and presided over by the Secretary of State for the Colonies in 1887 passed a resolution that the connection of Canada with Australia by direct submarine telegraph across the Pacific was a project of high importance to the empire. Of course those who had long enjoyed a monopoly might be expected to oppose competition, and he was not surprised at the protest made by those interested parties to her Majesty's Goverment. The cable companies which controlled the existing lines between the United Kingdom and Australasia "urged that the existing service was established solely by private enterprise," and without Government aid. These lines, however, had the advantage of being the first lines established, and thus had no opposition to contend with. The Pacific cable would, however, now have to compete with these very existing lines, which, whatever the case might have been when they were initiated, were now, and for many years past had been, assisted by annual subsidies. Altogether, the existing companies which would compete directly or indirectly with the Pacific cable had received in subsidies from various sources up to the present time more than £2,100,000, an amount much in excess of the capital required for a Pacific cable. He calculated that a total traffic of £96,250 might reasonably be looked for in the first year's working of the new cable. The protest against the cable was largely based upon fallacies. If the reasons urged by those who had so long enjoyed a monopoly should result in her Majesty's Government not giving the assistance required, the competition dreaded would not be prevented, but transferred to a company under the control of a foreign power, and England would have lost its opportunity. Australasia and Canada made no "demand" upon the taxpayers of this country, but, on the contrary, proposed to unite with the Imperial Government in providing an alternative line of steam and cable communication between England and Australasia and Canada, uniting those great possessions of the Crown more closely to each other and to the mother country, and furnishing in the best manner possible the means of expanding the trade and strengthening the unity and defence of the empire.

The discussion was opened by Sir JOHN COLOMB, who congratulated Sir Charles upon his address, and assured him that he had not taken up a hostile attitude to the Pacific cable and steamship services. Australasia and Canada were two portions of the empire which desired, and rightly desired, to come closer together. They wanted a mail route and a cable, and they asked the people of the United Kingdom to find a considerable portion of the money. They rested their claim on the ground that these things would contribute to the safety of the empire in case of war. As a cable or sea line could not protect itself, who was to protect it in such a case? He was not really opposed to these schemes, but merely asked who was to pay for the defence of the line. Canada paid less for naval and military defence than she ought to pay.

Mr. R. R. DOBELL, of Quebec, spoke next, and in the course of his observations said that Sir Charles Tupper's address would tend very much to strengthen the bonds already existing between the colonies and the mother country. He believed we were reaching a more intelligent conception of the grand scheme of Imperial federation, and, going back as he was to Canada in a few days, he should be able to carry back with him a very hopeful feeling that the people of this country were paying greater attention to their colonies.

The Hon. DUNCAN GILLIES (Agent-General for Victoria) warmly supported the proposal, and said that the colonies did not ask anything unreasonable in the matter from the Imperial Government. The Pacific steam route and cable were eminently desirable in the interests of the whole empire. As to who would protect the cable, he took it that England would never allow even the existing cable, which belonged to a company, to be interfered with, and he took it that, as a matter of honour, the Imperial Government would look after this cable, should it be laid. If the conference that was to be shortly held at Ottawa came to a conclusion in favour of the proposals, he was perfectly sure that the colonies would not be behindhand in their contributions.

Sir LAMBERT DOBSON (Chief Justice of Tasmania) said that the question resolved itself into one of whether the propositions put forth by the High Commissioner for Canada were beneficial to the empire. He had no hesitation in saying that the proposed line of communication would be valuable both to the mother country and the colonies, and if they agreed that the thing was good in itself, let them not be frightened by a possibility of what might occur in the event of war.

Sir GEORGE S. CLARKE followed, and warmly supported the propositions made by Sir Charles Tupper.

Mr. G. R. PARKIN, M.A., observed that the question Sir John Colomb had asked would have to be answered some day so far as the navy was concerned; but the time was not now ripe, and the tone in which it was asked was not a politic one. So far as military defence was concerned, remembering 1812, when 300,000 Canadians were more than a match for 3,000,000 invaders, he should say that Canada could take care of herself in any event. The Imperial interest in these cable and steamship lines was paramount.

The Hon. RICHARD O'CONNOR, M.L.C., of Sydney, and the Rev. Dr. LUCAS, of Canada, also spoke.

Lord LORNE having summed up the discussion, a vote of thanks to Sir Charles Tupper was unanimously adopted. A hearty vote of thanks was also given to the Marquis of Lorne for presiding, and the meeting terminated at rather a late hour.

Sir John Pender has addressed the following letter to Sir Charles Tupper:

"Winchester House, London, E.C., May 15, 1894.

"Dear Sir Charles Tupper,—I have carefully looked through the paper which you read last week at the meeting of the Royal Colonial Institute, and had I been well enough to attend the meeting I should have made an effort to be present.

"I cannot, however, allow your statement to pass unchallenged that the 'protest against the proposed cable is largely based upon fallacies,' feeling convinced that if you would carefully study our figures and arguments, which are based on actual facts and practical experience of cable working, and compare them with those furnished by Mr. Sandford Fleming, you would come to the conclusion that the fallacies are not on our side, but on your own.

"For instance, to take the first point in your paper relating to amortisation, you are entirely mistaken in stating that 'some 5,350 miles (or about 30 per cent.) of the 18,000 miles of cable now forming the system of the Eastern Extension Telegraph Company is more than 20 years old, and is still in working condition, the balance of about 12,650 miles being duplications and extensions laid since 1874.' As a matter of fact, nearly the whole of the cables orginally laid by the Eastern Extension Company have been renewed, some entirely, and in a considerable shorter period than 20 years.

"Then, as to your estimate of traffic for a Pacific cable, you have quite ignored the fact that at the Wellington Conference it was decided that the ordinary tariff should be 3s. per word, instead of 3s. 3d. as proposed by Mr. Sandford Fleming; consequently, after the necessary outpayments are deducted, which would probably amount to 1s. 6d. (1s. for the Atlantic cables and 6d. for the Canadian and Australian land lines), there would be only 1s. 6d. left for the Pacific cable instead of the 2s. relied upon by Mr. Sandford Fleming, and this discrepancy materially affects your figures.

"Moreover, any calculations based upon such an unknown quantity as the 'normal increase of traffic' cannot be at all reliable, as the circumstances are constantly changing. For example, the growth of traffic with Australasia during the year ending April 30, 1892, was only 8·34 per cent. over that of the previous year, and in the following year, ending April, 1893, it was less than 6 per cent., as compared with 1892, showing that Mr.

Digitized by Google

Sandford Fleming's estimate of a minimum 12½ per cent. is quite misleading.

"It is equally unsafe to rely too closely on calculations of increase resulting from reductions of tariff, experience having unfortunately shown that on more than one occasion a falling off of traffic has actually taken place after a substantial lowering of rates, instead of a considerable increase such as your paper indicates would result if the Australian tariff were reduced from 4s. 9d. to 3s. 3d. per word.

"Then, again, your description of the existing system as a 'monopoly' cannot be justified, seeing that it has never received any exclusive landing rights from the Australian Governments, but has had to rely upon the business-like and economical principles upon which it has been established and worked for its freedom from competition. In fact, the field has always been open to all comers to compete with us, and upon equal terms I should have nothing to say against it, but supported by Government aid it would be quite another matter, and if a Pacific cable were established on this basis and the pioneer company, which has done so much for the Australasian colonies in providing them with perhaps the best submarine service in the world, were ignored, it would certainly be disastrous to private enterprise, and the Governments interested could not in common fairness adopt such a course without granting similar pecuniary assistance to the existing system.

"No doubt a single cable could be constructed and laid for £1,800,000, and it would undoubtedly materially benefit the cable manufacturers, but no company who knew anything about the business and would be held responsible for carrying it through could undertake the work with any prospect of making it pay on the terms of the Wellington Conference resolution.

"At the present moment, however, the proposed cable is not really needed for commercial purposes, and therefore the expenditure of nearly two millions sterling, when neither the Imperial nor Colonial Governments can well afford it, would, in my opinion, be an unwarrantable waste of money.

"If, however, the Governments concerned consider a second cable is required for strategic purposes, which I very much doubt, they must, of course, pay for it, and, as I have frequently stated, my company would be quite prepared to undertake the work on fair and reasonable terms, which terms would necessarily be more favourable to the Governments than could be obtained from any other company, owing to the exceptional facilities possessed by the existing system.

"The probability of opposition arising from foreign sources does not in the least alarm me, but should competition be brought about through English and colonial agencies on the proposed terms the result must inevitably be that no dividend would be forthcoming for the new company, and little, if any, for the pioneer service.

"I have thought it only fair to yourself as well as to the companies which I represent that you should be placed in possession of the above information, as you will doubtless be making further reference to the Pacific cable movement, and, with so much attention now being paid to all public utterances on the subject, it is of the greatest importance that all figures bearing on the question should be as accurately stated as possible.

"I am sending a copy of this letter to the *Times*.

"Yours faithfully,

"JOHN PENDER.

"Sir Charles Tupper, Bart, G.C.M.G., C.B., etc."

TELEGRAPHS AND TRADE ROUTES IN PERSIA.*

BY LIEUT.-COLONEL HENRY L. WELLS, R.E.

The interest taken in the paper on "Telegraphic Communication between England and India," which was read to this society in February last, led to my being asked to give an account of the Indo-European telegraphs in Persia, and of the local telegraphs in that country from the time that I became acquainted with their administration—viz., January 1881; and secondly, to bring the history of the trade routes in Persia up to date, a subject which has attracted much attention on the part of my predecessors, as evinced by papers read thereon by three successive directors of telegraphs. The Indo-European Telegraph Company comes from London *vid* Lowestoft, Emden, Berlin, Warsaw, Odessa, Kertch, Sukumkaleh, Tiflis, and enters Persia at the passage of the River Araxes, which forms the frontier between that country and Russia. Since 1880 a great improvement has been effected in the working of their line, by carrying two of the wires on bare porcelain insulators, supported at either end of an oaken arm, which is attached to the iron standards of the Siemens pattern. This system of insulation is the very best yet devised for long-distance land lines in Central Asia. The third wire is still carried as formerly on a Siemens iron hooded insulator, which is attached underneath the oaken arm above referred to, and is for the use of the Persian Government. The companies' lines are well constructed and admirably maintained. The Persian portion of their system traverses a very elevated plateau; for instance, at Zenjan, the whole surface of the country has an elevation varying from 5,000ft. to 6,000ft. above the sea. The distance from Djulfa, where the line crosses the Araxes, to Teheran is 440 miles. The line runs parallel to the main mountain chains, which protect it from the north winds. Throughout the above-mentioned distance, the altitude of the country passed over by the line does not vary more than 3,000ft. This fact, together with that of its being protected by the mountain ranges, accounts for the singular immunity from interruptions it enjoys.

Since I was placed in charge of the construction branch of the lines in 1881, the whole length has been bit by bit overhauled, the supports being in many instances placed closer together, and the direction of the line changed where experience showed such change advisable. The result has been a vast improvement, as shown by the wonderful immunity from interruption the line now enjoys. The system of insulation, moreover, has been improved, and all three wires are now carried on porcelain insulators, supported on malleable iron brackets, which are bolted round the Siemens standards. The third wire is here also for the use of the Persian Government. At Teheran, the capital, the Indo-European Company's administration terminates, and that of the Government commences. The Indo-European line runs south from Teheran to Kom, skirting the great desert on its western extremity. The distance by this route from Teheran to Kom was 84 miles. From Kom the line skirts the desert to Kashan and passes through villages which used to be liable to be pillaged by Turcomans. The altitude of Kom is 3,100ft. From Kashan, which has an altitude of 3,200ft., the line following the shortest route to the south rises 5,500ft. in 32 miles to the summit of the Kohrud Pass, which has an altitude of 8,750ft. This is a difficult piece of line to keep free from interruption during winter, and it took several years to find the best direction for the wires, and overcome the difficulties due to the intricacies of the rock-bound defiles, and the sudden gusts of snow-laden wind that rush through them. The third sub-section extends from Meshad-i-Moorgab to Mian-Kotul, a distance of 131 miles. The fourth section extends from Mian-Kotul to the sea, and is the only one which is below the winter snow line—distance 102 miles. The total length of line is 675 miles.

Gradually, by substituting poles of cypress wood—which white ants do not touch—for those of poplar, by cutting out the bad wire and making good joints, fitting up the offices, and renewing the instruments, and, by transferring the utterly worthless members of the staff, the period of interruption has been reduced from 1,600 hours in 1887 to 543 in 1893. The system of dual control, which is now producing results with which H.I.M. the Shah expresses himself highly pleased, is feasible, thanks to the large-mindedness and liberal spirit of his Excellency the Mukhber-ed-Dowleh. The line suffers most severely from camels. These animals, when casting their coats in the autumn, go for the telegraph line. Nothing but iron standards, with spreading foot-plates, will overcome this difficulty. If this line is to be kept up, and in the future prolonged through Herat and Candahar to the British frontier at Chaman, it must be entirely reconstructed with Siemens iron standards ere it can be considered an efficient or thoroughly reliable means of communication.

* Abstract of paper read before the Society of Arts.

ELECTRICITY IN MINING OPERATIONS.

A number of pumping, haulage, and lighting contracts at various collieries, in addition to a number of mills, factories, shops, and complete plants for country residences, has recently been carried out by Messrs. John Davis and Son, of Derby.

In the case of the combined lighting and haulage plant erected by that firm for the West Hallam Colliery Company, near Derby, the dynamo is compound wound, of 50 h.p., and is driven by an endless belt from a pair of horizontal engines. This machine supplies current for lighting the offices, shops, pit banks, yards, etc., on the surface with incandescent and arc lamps, the main roads underground with incandescent lamps protected by special damp and dust proof fittings, and also for a 10-h.p. motor employed for haulage. Since the motor was started, not a single ton of coal has been lost, and, moreover, this one machine has displaced 14 horses in the pit, besides dealing with a much larger quantity of coal than previously. This plant is now being extended to a 20-b.h.p. combined pumping and haulage plant, for hauling by day and pumping by night, and a separate 10-h.p. motor and pump for dip pumping. Another colliery pumping plant recently installed for the Ackton Hall Colliery Company, near Pontefract, consists of a 25-h.p. motor and pump forcing 12,000 gallons per hour up a vertical height of 240ft.; the cables are of the concentric type insulated with vulcanised indiarubber and carried down the shaft in wrought-iron pipes as an extra precaution

Digitized by Google

against mechanical injury. Another small pump and motor to force 360 gallons per hour up a vertical height of 1,200ft. is also at work.

Messrs. John Davis and Son are putting down electric motors provided with their safety commutators at long distances from the pit bottom in districts in which the use of locked safety lamps is imperative. A combined lighting and pumping plant, with the motor constructed under the firm's patent, has been erected for the Clay Cross Company at their Morton Colliery. The lighting consists of lamps varying from 16 c.p to 150 c.p. on the surface, and underground. in addition to a number of lamps, there is laid down a 3-h.p. safety commutator or motor driving a three-throw pump forcing 600 gallons per hour up a vertical height of 128ft. through 2,400ft. of 2in. pipes. The motor and pump are situated one mile from the dynamo, and are now doing in one quarter of the time three times the work originally done by horses. Another pumping plant, with spare power for lighting, has just been erected for the Wingerworth Colliery Company, near Chesterfield, for clearing the flooded workings. It is situated one mile from the dynamo, and is forcing 1.200 gallons per hour up a vertical height of 150ft. through 2,400ft. of 7in. pipe. In order to deal with the water quicker, a duplicate plant is now being constructed to deliver its water on the surface. As a type of export plant we may mention that supplied by Messrs. John Davis and Son to the St. John Del Rey Mining Company, for lighting their stamp mills, shops, yards, engine-houses, mines, and managers' residences with arc and incandescent lamps. The plant consists of a compound-wound dynamo specially constructed for transport driven by a Pelton waterwheel, switchboard with regulating and controlling switches, measuring instruments, lamps, brackets, fittings, etc., complete. The dynamo is situated one mile from the nearest lamps; the pressure is, however, kept constant at all loads by means of a special arrangement of connections. These are only a few of the most recent plants erected by the firm, the list of work executed during the last 12 months containing, amongst others, the Lea lead-works of Messrs. Wass and Sons, and a number of collieries and works.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION'S STANDARD RULES FOR ELECTRICAL CONSTRUCTION AND OPERATION.

(Concluded from page 443.)

CENTRAL STATIONS.

CLASS C.—OVERHEAD CONDUCTORS—INCANDESCENT (LOW PRESSURE) SYSTEMS (300 volts or less).

Outside Overhead Conductors.

1. Must be erected in accordance with general rules for arc (series) circuit conductors.
2. Must be separated not less than 6in. where they enter buildings as service conductors, and be provided with a double-pole fusible cut-out, as near as possible to the point of entrance to the building, and outside the walls when practicable.

Underground Conductors.

1. Must be provided with suitable protecting devices at the ends of tube or conduit services inside the walls of buildings, as a guard against moisture and injury.
2. Must be terminated at a properly placed double-pole house cut-out.
3. Must be of specially insulated conductors after leaving the tube or conduit, and separated by at least 10in., until the double-pole cut-out is reached.

Inside Wiring.

1. Where practicable wire, should be so placed that in the event of the failure or deterioration of their insulating covering the conductors under this condition will still remain insulated.
2. At the entrance of every building there shall be a double-pole switch placed in the service conductors, whereby the current may be entirely cut off.

Conductors.

1. Must not be of sizes smaller than No. 16 B. & S., No. 18 B.W.G., or No. 3 E.S.G.
2. Must not be paraffin covered.
3. Must not be covered with soft rubber tube.
4. Must not be laid in mouldings of any kind in damp places.
5. Must not be laid in mouldings with open grooves against the wall or ceiling.
6. Must not be laid in mouldings where less than ¼in. of solid insulation is between parallel wire, and between wires and walls or ceilings.
7. Must not be laid in plaster, cement, or similar finish, without an exterior metallic protection.
8. Mouldings, where admissible, must have at least two coatings of waterproof paint, to be impregnated with a moisture repellent.

Cleatwork.

1. Cleatwork is not desirable, and cleats must not be used unless in a very dry place.
2. Must not be used unless in a place perfectly open for inspection at any time.
3. Must not be used unless they are of porcelain, or well-seasoned wood, filled, to prevent absorption of moisture.
4. Must not be used unless they are so arranged that wires of opposite polarity, with a difference of potential of 150 volts, or less, will be kept at least 2½in. apart, and that where a higher voltage is used this distance be increased proportionately.
5. Must not be used unless there is a backing provided of wood at least ½in. thick, well seasoned and filled to prevent absorption of moisture.

Metal Staples.

1. Metal staples must never be used to fasten conductors unless provided with an insulating sleeve or saddle rigidly attached to the metal of the staple, and having such strength and surface as to prevent mechanical injury to the insulation of the conductor.
2. Must never be used to fasten conductors unless under conditions in which cleatwork would be acceptable, or where driven into a moulding specially adapted for open work.

Special Wiring.

1. Whenever conductors cross gas, water, or other metallic pipes, or any other conductors or conducting materials (except arc light wires), they should be separated therefrom by some continuous non-conductor at least 1in. In crossing arc light wires the low-tension conductors must be placed at a distance of at least 6in. In wet places an air space must be left between conductors and pipes in crossing, and the former must be run in such a way that they cannot come in contact with the pipe accidentally. Wires should be run over all pipes upon which condensed moisture is likely to gather, or which by leakage might cause trouble on a circuit.
2. In rooms where inflammable gases may exist, or where the atmosphere is damp, the incandescent lamp and socket should be enclosed in a vapour-tight globe. This is not to be understood to include rooms where illuminating gases are used in the ordinary manner.
3. In breweries, stables, dye-houses, paper and pulp mills, or other buildings specially liable to moisture, all conductors, except where used for pendants:
4. Must be separated at least 6in.
5. Must be provided with a durable moisture-proof covering.
6. Must be carefully put up.
7. Must be supported by porcelain or glass insulators.
8. Moisture-proof and non-inflammable tubing may be accepted in lieu of such construction.
9. No switches or fusible cut-outs will be allowed in such places.

Interior Conduits.

1. Must not be combustible.
2. Must not be of such material or construction that will be injured by plaster, cement, or other surrounding material, or that the insulation of the conductor will ultimately be injured or destroyed by the elements of its composition.
3. Must not be so constructed or placed that difficulty will be experienced in removing or replacing the conductors.
4. Must be continuous from one junction-box to another or to fixtures, and of non-inflammable material, and of a substantial character, as in the case of the existing gas and water pipes, in order to afford mechanical protection from injury by saws, chisels, or nails.
5. Whenever practicable, pipes for all purposes must be kept from the conduits or wire-ways, and under no circumstances must steam-pipes be placed therein.
6. Architects and builders should provide suitable wire-ways or openings in all buildings at the time of their construction, in which could be placed electric wires and conduits according to the requirements of the building.
7. Prior to the insulation of the wires, powdered soapstone should be blown through the conduit tubes to facilitate the drawing in of the same.
8. Must not be depended upon for insulation. The conductors should be covered with moisture-proof material.
9. The object of a tube or conduit is to facilitate the insertion or extraction of the conductors, to protect them from mechanical injury and, as far as possible, from moisture.
10. Conductors passing through walls or ceilings must be encased in a suitable tubing, which must extend at least 1in. beyond the finished surface until the mortar, or other similar material, be entirely dry, when the projection may be reduced to ½in.

Double-Pole Safety Cut-Outs.

1. Must be placed where the overhead or underground conductors enter a building and join the inside wires.
2. Must be placed at every point where a change is made in the size of the wire (unless the cut-out in the larger wire will protect the smaller). This includes all flexible conductors. All such junctions must be in plain sight.
3. Must be constructed with bases of non-combustible and moisture-proof material.
4. Must be so constructed and placed that an arc cannot be maintained between the terminals by the fusing of the metal.
5. Must be so placed that on any combination fixture no group of lamps requiring a current of six amperes or more shall be ultimately dependent upon one cut-out.
6. Must be, wherever used for more than six amperes, or (where the plug or equivalent device is not used) equipped with fusible strips or wires, provided with contact surfaces or tips of harder metal, soldered or otherwise, having perfect electrical connection with the fusible part of the strip.

Safety Fuses.

1. Safety fuses must be so proportioned to the conductors they are intended to protect that they will melt before the maximum safe carrying capacity of the wire is exceeded.
2. All fuses, where possible, must be stamped, or otherwise marked, with the number of amperes equal to the safe carrying capacity of the wire they protect.

Digitized by Google

3. All cut-out blocks when installed must be similarly marked.

4. The safe carrying capacity of a wire changes under different circumstances, being about 40 per cent. less when the wire is closed in a tube or piece of moulding than when bare and exposed to the air, when the heat is rapidly radiated. It must be clearly understood that the size of the fuse depends upon the size of the smallest conductor it protects, and not upon the amount of current to be used on the circuit. Below is a table showing the safe carrying capacity of conductors of different sizes in Birmingham, Brown and Sharpe, and Edison gauges, which must be followed in the placing of interior conductors.

Brown & Sharp.		Birmingham.		Edison Standard.	
Gauge No.	Amperes.	Gauge No.	Amperes.	Gauge No.	Amperes.

Switches.

1. Must be mounted on moisture-proof and incombustible bases, such as slate or porcelain.

2. Must be double pole when the circuits which they control are connected to the fixtures attached to gas-pipes, and when six amperes or more are to pass through them.

3. Must have a firm and secure contact, must make and break readily, and not stick when motion has once been imparted by the handle.

4. Must have carrying capacity sufficient to prevent heating above the surrounding atmosphere.

5. Must be placed in dry accessible places, and be grouped, as far as possible, being mounted, when practicable, upon slate or equally indestructible back-boards.

Motors.

1. In wiring for motive power, the same precautions must be taken as with the current of the same volume and potential for lighting. The motor and resistance-box must be protected by a double-pole cut-out, and controlled by a double-pole switch.

Arc Lights on Low-Potential Circuits.

1. Must be supplied by branch conductors, not smaller than No. 12 B. & S. gauge.

2. Must be connected with main conductors only through double-pole cut-outs.

3. Must be furnished only with such resistances or regulators as are enclosed in non-combustible material, such resistances being treated as sources of heat.

4. Must be supplied with globes protected as in the cases of arc lights on high-potential circuits.

Fixture Work.

1. In all cases where conductors are concealed within, or attached to, fixtures, the latter must be insulated from the gas-pipe system of the building by an insulating joint, the material of which shall not be affected by gas or changes of temperature.

2. When wired outside, the conductors must be so secured as not to be cut or abraded by the pressure of the fastenings or motion of the fixtures.

3. All conductors for fixture work must have waterproof insulation that is durable and not easily abraded, and must not in any case be smaller than No. 16 B. & S., No. 18 B.W.G., or No. 3 E.S.G.

4. All burrs or fins must be removed before the conductors are drawn into a fixture.

5. The tendency to condensation within the pipes must be guarded against by sealing the upper end of the fixture.

6. No combination fixture in which the conductors are concealed in a space less than ¼in. between the inside pipe and the outside casing will be approved.

7. Each fixture must be tested for possible "contacts" between conductors and fixture, and for "short-circuits," before the fixture is connected to its supply conductors.

8. The ceiling blocks of fixtures should be made of insulating material.

Electric Gas Lighting.

Where electric gas lighting is to be used on the same fixture with the electric light:

1. No part of the gas-piping or fixture shall be in electrical connection with the gas lighting circuit.

2. The wires used with the fixture must have a non-inflammable insulation, or, where concealed between the pipe and shell of the fixture, the insulation must be such as is required for fixture wiring for the electric light.

3. The whole insulation must test free from "grounds."

4. The two installations must test perfectly free of connection with each other.

Pendants and Sockets.

1. No portion of the lamp socket exposed to contact with outside objects must be allowed to come into electrical contact with either of the conductors.

Cord Pendants.

1. Must be made of conductors, each of which is composed of several strands insulated from the other conductor by a mechanical separator of carbonisable material, and both surrounded in damp places with a moisture-proof and a non-inflammable layer.

2. Must be protected by insulating bushings where the cord enters the socket.

3. Must be so suspended that the entire weight of the socket and lamp will be borne by knots above the point where the cord comes through the ceiling block or rosette, in order that the strain may be taken from the joints and binding screws. All sockets used for wire or cord pendants should have openings at least equal to ¼in. gas-pipe size.

4. Must be allowed to sustain nothing heavier than a four-light cluster, and in such a case special provision should be made by an extra heavy cord or wire, as a mechanical reinforcement.

5. Must be equipped with keyless sockets, as far as practicable, controlled by wall switches. In no case may a lamp giving more than 50 c.p. be placed in a key socket on a flexible pendant.

Electric Heating and Cooking.

1. In general the same precautions should be taken in the installation and operation of electric heating and cooking appliances as are applicable to circuits for electric light and power.

2. The practice of attaching heating and cooking appliances to lamp-sockets must not be permitted where said appliances require over three amperes. Proper circuits must be provided, fully protected by double-pole safety fuses and switches, and the appliances themselves should be kept from contact with inflammable materials.

3. Flexible cords should be used with strands separately covered with non-inflammable insulation, and both wires or strands covered with a water-proofing, and that by a braiding, and especial care should be taken to make proper connections on all appliances, and each should be plainly marked with the maximum volts and amperes they will safely carry.

CLASS D.—ALTERNATING SYSTEMS.

Converters or Transformers.

Converters.

1. Must not be placed inside of any building, except the central station, unless as hereinafter provided.

2. Must not be placed in any but metallic or non-combustible cases, which cases should be connected to earth when wires are underground.

3. Must not be attached to the outside walls of buildings unless separated therefrom by substantial insulating supports.

4. Must not be placed in any other than a dry and convenient location (which can be secured from opening into the interior of the building, such as a vault), when an underground service is used.

5. Must not be placed without safety fuses at the junction between main and service conductors, and safety fuses in the secondary circuits where they will not be affected by the heat of the converter.

Primary Conductors.

In those cases where it may not be possible to exclude the transformers and primary wires entirely from the building, the following precautions must be strictly observed:

1. The transformer must be located at a point as near as possible to that at which the primary wires enter the building.

2. The primary lead of a transformer should be heavily insulated with the highest-class insulation—such as vulcanised pure indiarubber of the best quality, preferably covered with a high-class outer covering, and such leads should have a minimum length of 18in.

3. Between these points the conductors must be heavily insulated with a coating of moisture-proof material, and, in addition, must be so covered and protected that mechanical injury to them or contact with them shall be practically impossible.

4. The primary conductors, if within a building, must be furnished with a double-pole switch, and also with a double-pole cut-out where the wires enter the building, or where they leave the main line on the pole or in the conduit. These switches should, if possible, be enclosed in secure and fireproof boxes outside the building.

5. The primary conductors, when inside a building, must be kept apart at least 10in., and at the same distance from all other conducting bodies.

Secondary Conductors.

1. The conductors from the secondary coil of the transformer to the lamps, or other translating devices, must be installed according to the rules for "inside wiring" for "Low-Potential Systems."

2. Section 1 under primary conductors and referring to primary leads, applies with equal force to the secondary leads.

CLASS E.—ELECTRIC RAILWAYS.

Power Stations.

1. All rules pertaining to arc light wires and stations shall apply (so far as practicable) to street railway power stations and their conductors.

Railway Systems with Ground Return.

Electric railway systems in which the motor cars are driven by a current from a single wire, with ground or floor return circuit, are prohibited, except as hereinafter provided.

Digitized by Google

1. When there is no liability of other conductors coming in contact with the trolley wire.

2. When the location of the generator is such that the ground circuit will not create a fire hazard to the property.

3. When an approved automatic circuit breaker, or other device that will immediately cut off the current in case the trolley wires become grounded, is introduced in each circuit as it leaves the power station. This device must be mounted on a fireproof base, and be in full view of the attendant.

Trolley Wires.

1. Must be no smaller than No. 0 B. & S. copper, or No. 4 B. & S. silicon bronze, and must readily stand the strain put upon them when in use.

2. Must be well insulated from their supports, and in case of the side or double-pole construction, the supports shall also be insulated from the poles immediately outside the trolley wire.

3. Must be capable of being disconnected at the power-house, or of being divided into sections, so that, in case of fire on the railway route, the current may be shut off from the particular section and not interfere with the work of the firemen in extinguishing the flames. This rule also applies to feeders.

4. Must be safely protected against contact with all other conductors.

Car Wiring.

1. All wires in cars must be run out of reach of the passengers, and shall be insulated with a waterproof insulation.

Lighting and Railway Power Wires.

1. Lighting and power wires must not be permitted in the same circuit with trolley wires with a ground return, except in street railway cars, car-houses, and power stations. The same dynamo may be used for both purposes, provided the connection from the dynamo for each circuit shall be a double-pole switch, so arranged that only one of the circuits can be in use at the same time.

2. The lines of any electric railroad system employing a ground return must under no circumstance be taken into any building for light, power, or other purposes, save in the house of the power and car houses of the company.

3. Where light or power is supplied from the railway circuits employing a ground return for use in the power-house or car-house of the company, only the highest class of approved insulated wire must be used, the same to be supported on insulators and readily accessible at all times. Inflammable moulding or casing concealing the wires must not be used.

4. Switches constructed for 50 and 100 volts potential must not be used upon railway circuits, particularly where current is used for lighting purposes.

CLASS F.—BATTERIES.

Primary or Secondary Batteries.

1. Secondary batteries or accumulators should be placed in a light and well-ventilated place, preferably upon racks, and thoroughly well insulated.

2. Frequent examinations should be made of the connections and the specific gravity of the solution.

3. When current for light and power is taken from primary or secondary batteries, the same general regulations must be observed as apply to such wires fed from dynamo generators developing the same difference of potential.

CLASS G.—MISCELLANEOUS.

1. The wiring in any building must test free from "grounds" before the current is turned on. This test may be made with a magneto bell that will ring through a resistance of 20,000 ohms where currents of less than 250 volts are used.

2. No ground wires for any purpose may be attached to gas-pipes within the building.

3. All conductors connecting with telephone, district messenger, burglar alarm, watch clock, electric time and other similar instruments, must, if in any portion of their length they are liable to become crossed with circuits carrying currents for light or power, be provided near the point of entrance to the building with some protective device which will operate to shunt the instruments in case of a dangerous rise of potential, and will open the circuit and arrest an abnormal current flow. Any conductor normally forming an innocuous circuit may become a source of fire hazard if crossed with another conductor through which it may become charged with a relatively high pressure.

PHYSICAL SOCIETY.

At a meeting of this society on the 11th inst., Mr. Walter Baily, M.A., vice-president, in the chair,

A mathematical communication **"On Electromagnetic Induction in Plane, Cylindrical, and Spherical Current Sheets, and its Representation by Moving Trails of Images," Part I.: "General Equations,"** by **Mr. G. H. Bryan, M.A.**, was read by Dr. C. V. Burton, who also explained some of the parts in greater detail. After mentioning that the magnetic field due to induced currents in thin conducting sheets placed near moving magnetic poles could be represented by moving trails of images of those poles, the author goes on to say that in the paper the surface conditions which hold at the surfaces of the sheets are deduced directly from the fundamental laws of electromagnetic induction. I.: "The total current across any enclosed portion of a surface which always contains the same particles is equal to $\frac{1}{4}\pi$ of the line integral of the magnetic force round the curve bounding the surface"; and II.: "The rate of decrease of the surface integral of magnetic induction across any enclosed surface, which always contains the same particles, is equal to the line integral of E.M.F. round the curve bounding the surface." In addition to the above laws, the author makes the usual assumptions that displacement currents in the dielectric are so small as to be negligible, and that the induced currents are distributed uniformly through the thickness of the sheet. On these suppositions the surface conditions satisfied by the potentials at the two sides of a plane, cylindrical, or spherical sheets are determined, and, with an additional limitation as to the thickness of the sheet fulfilling certain conditions, extended to current sheets of other forms. In the latter part of the paper a synthetic determination of the images in a plane sheet is given and expressed in the form of a definite integral. In reading the paper to the meeting, Dr. Burton pointed out several misprints in the proof. **Prof. Minchin** showed that equation (1) of the paper ($\Omega_2 - \Omega_1 = 4\pi\phi$ + constant, where Ω_2 and Ω_1 are the magnetic potentials at the two sides of the sheet, and ϕ the current function) could be deduced by purely mathematical reasoning, instead of being based on the laws of electromagnetic induction. Moreover, it was true for any function whatever, and did not depend on ϕ being the current function. Equation (2) $\left(\frac{d\Omega_2}{d2} = \frac{d\Omega_1}{d2}\right)$ followed immediately from the fact that the magnetic force was continuous. The latter part of the paper might be simplified by integrating the linear partial differential equation (15) $\left(\frac{d^2\Omega^1}{dz\,dt} - R\frac{d^2\Omega^1}{dz^2} = -\frac{d^2\Omega_0}{dz\,dt}\right)$ in the ordinary way, for the form was one for which the auxiliary equations are well known. **Dr. Burton**, in reply, said he thought Mr. Bryan's reason for developing the equations from the laws of electromagnetic induction was to give his work a physical rather than a mathematical basis.

A paper **"On Dielectrics"** was read by **Mr. Rollo Appleyard**. In testing the insulation resistances of celluloid by having a sheet pressed between two metal plates, the author noticed that the resistance, which was very high, *decreased* as the time the testing battery was left on increased. The "electrification" (using the word to indicate the rate of diminution of galvanometer deflection) was, therefore, *negative*. The resistance also diminished greatly with increase of battery power, and a considerable amount of hysteresis was observed in the resistance at any given voltage, after a minute's electrification, depending on the previous history of the specimen. On making contact with the surfaces of the celluloid by mercury instead of by solid metal, the abnormal results disappeared, little or no resistance, hysteresis, or "electrification" being present, and only a small diminution of resistance with increase of voltage. For a six-mil sheet the resistance between opposite faces 5½in. diameter was of the order 30 megohms, and one specimen broke down at 1,200 volts. The celluloid condensers used in the experiments were found to discharge slowly at first, and after a certain time the deflections of the galvanometer became reversed and attained a steady negative value. This the author attributes to an E.M.F. of about 0·0006 volt between the mercury and celluloid. Similar experiments on guttapercha tissue showed no such E.M.F., and the "electrification" was normal. The resistance usually attained a maximum for voltages between 600 and 800. Although the tissue had a thickness of only two mils (0·002in.), it stood a pressure of 1,200 volts, and offered a resistance between circular faces 5½in. in diameter of about 3,000 megohms. The opaque white spots seen in celluloid under the microscope led the author to test the behaviour of mixtures of conducting and insulating materials. A strip of guttapercha was warmed, and coarse brass filings scattered over it as thickly as possible. In spite of this the resistance was practically infinite even when tested with 750 volts. A number of rods were made from mixtures of brass and guttapercha in various proportions, and on testing these it was found that if the weight of filings exceeded about twice that of the guttapercha, the resistance of a rod 20in. long, ⅜in. diameter, was small (sometimes a fraction of an ohm), whereas a slightly smaller proportion yielded rods having resistance measured in thousands of megohms. Such rods were found to be affected by oscillating discharges in a manner similar to Prof. Minchin's "impulsion" cells and M. Branby's tubes of filings. Experiments were also made on the behaviour of such rods when subjected to high alternating pressures. This caused small local arcs to form along the rods, but did not permanently destroy their high resistance.

In connection with Mr. Appleyard's paper, **"A Note on the Behaviour of Certain Bodies in Presence of Electromagnetic Oscillations,"** by **Prof. G. M. Minchin, M.A.**, was read by Mr. Elder. Referring to the employment of impulsion cells, metallic films, etc., for detecting the nodes of electromagnetic vibrations, he says that so far the physical states of such bodies are too variable to be of service. Metallic surfaces, formed by embedding fine metallic powders in films of gelatine, shellac, or sealing-wax, are, as described in a previous communication to the society, found to act as insulators, but become conducting when subjected to strong electromagnetic disturbances. After a current has once passed through such a film its resistance is changed by very feeble impulses, whereas previously it failed to respond to strong ones. On breaking contact by removing the electrode from the surface, the film loses its conductivity, the time necessary to do this depending on the hardness of the matrix. The resistance of a film containing tin powder, measured between the rounded tips of two platinum wires 1cm. apart, varied under the electromagnetic impulses from ∞ to 130 ohms. In conclusion, the author points

Digitized by Google

out that with films and tubes the whole phenomenon relates to change of resistance, whereas impulsive cells may have currents from external sources passing through them whilst in either the sensitive or insensitive states. **Mr. Bright** and **Mr. Enright** asked questions as to the electrification of guttapercha and the bridge connections in the resistance tests of the semi-conducting rods respectively, to which **Mr. Appleyard** replied.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,891.

Toxteth.—The Board of Guardians are considering the question of lighting the workhouse by electricity.

Guildford.—The Town Council have again discussed the question of the provisional order, referred to in our last issue.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 13th inst. amounted to £824.

Dundee.—During the past month 504 Board of Trade units of electricity were supplied to the four arc lamps on High-street, at a cost of £10. 10s.

Winchester.—The county surveyor is to report to the County Council on the question of introducing the electric light into the new offices.

Coatbridge.—The Town Council are to ask the electric lighting company to estimate for the lighting of the streets over the area covered by their plant.

Birkenhead.—The Mersey Docks and Harbour Board intend to construct a new jetty at Birkenhead at a cost of £7,500. It is to be lighted by electricity.

Wolverhampton.—The Local Board of Health of Heath Town, Wolverhampton, propose to consult an electrical engineer on the subject of electric lighting.

Worcester.—The tender of the Brush Electrical Engineering Company has been accepted, at £1,861, by the Town Council for laying mains for 26 arc lamps.

Weston-super-Mare.—The Town Commissioners have sent out papers asking for the names of those willing to take the electric light. A number of favourable answers has now been received.

Burnley.—Various alterations have been made at the Central Club, and the electric light has been installed by Messrs. Spagnoletti and Crookes, under the local management of Mr. E. H. Berry.

Removal.—Messrs. King and Co. inform us that they have removed from Edinburgh to new business premises in Leith, and that their address is now at Leith Electric Works, Prince Regent-street, Leith.

Derby.—Messrs. J. Davis and Son have received instructions from the Corporation of Derby to instal arc and incandescent lamps, with distributing boards, measuring instruments, etc., for lighting the Market Hall, galleries, and approaches.

Wrigley's Patent, Limited.—This Company has been registered with a capital of £60,000 in £1 shares. The object is to acquire certain patents granted to Thomas Wrigley, and to carry on business as ironfounders, mechanical and electrical engineers.

Electric Lighting Concessions.—"Malaysia," care of Messrs. Street and Co., Cornhill, announces that he has electric light concessions for disposal for Oriental towns of 120,000 and 30,000 inhabitants, with contingent Government contracts or subsidies for lighting.

Chertsey.—At a meeting of the Rural Sanitary Authority Mr. Chambers said the Weybridge Parochial Committee had decided to call the attention of the electric lighting company to the poles in the village. They thought something ought to be done in reference to pulling them down

Ballymena.—The Town Commissioners, in connection with the proposed lighting of the locality by electricity, have expressed an opinion that until a much less expensive scheme than the one which they had been recently asked to consider were put forward, they would not be in a position to entertain it.

Eton.—The Local Board have received a communication from the Windsor Electric Lighting Committee of the Town Council suggesting a consultation with the Board on the subject of electric lighting. A committee of five members of the Board has been appointed to meet a sub-committee from Windsor.

Tenders for St. Pancras.—The Vestry of St. Pancras invite tenders for the buildings to contain the electric lighting plant (engines, dynamos, boilers, etc.) to be carried out at the electric lighting and refuse destructor station, King's-road, Camden Town, N.W. Tenders are to be sent in by Monday, 21st inst.

City and South London Railway.—The receipts of the Company for the week ended May 13 were £905, against £787 for the same period last year, or an increase of £118. The total receipts for the first half-year of 1894 show an increase of £364 compared with those for the corresponding period of 1893.

Stafford.—The Electric Lighting Committee of the Town Council have received the report of Dr. Hopkinson on the engines for the electric lighting station. The committee advised the purchase of three horizontal compound steam-engines from Messrs. Marshall, Sons, and Co., for £2,420. The report has been adopted.

British Aluminium Company, Limited.—This Company has been registered with a capital of £100,000 in £10 shares. The object is to acquire any mineral, clay, and other deposits suitable for the production of aluminium, sodium, and other metals; also the rights for getting the same, and the production and supply of electricity.

Church-Lighting.—Messrs. Rashleigh Phipps and Co. have received instructions from the Marylebone Presbyterian Church, Upper George-street, Edgware-road, to instal an additional 200 lights in the church. This is the second order placed in the hands of this firm, who lighted the vestries and committee-rooms in the autumn of last year.

County of London and Brush Company.—The Board of the County of London and Brush Provincial Electric Lighting Company have passed resolutions appointing the Right Hon. D. R. Plunket, Q.C., M.P., and Mr. Anthony Noel Denny, directors of the Company. The directors also passed a resolution electing the Right Hon. D. R. Plunket as chairman of the Board.

The Strand District.—The Strand District Board of Works have referred to the Works Committee an application of the secretary of the Charing Cross and Strand Electricity Supply Corporation for the Board's sanction and approval to a provisional order from the Board of Trade, so as to enable the corporation to supply electrical energy within the parish of St. Paul's, Covent Garden.

Bolton.—The electrical engineer to the Corporation has been requested by the Gas and Electricity Committee to prepare a scheme for carrying out a hire-purchase system of electrical fittings, by which consumers can both hire and purchase the fittings simultaneously. Good progress is being made with the electricity works, and the laying of the underground mains has been commenced.

Tenders for Tunbridge Wells.—The Corporation invite tenders for the construction, supply, and laying down of the necessary plant and mains for the supply of electricity in the borough, in accordance with the specifications, plans, and form of tender which can be obtained from Mr. W. C. Cripps, town clerk, Town Hall, Tunbridge Wells, on payment of £2. 2s. Tenders, endorsed "Electricity," are to be delivered at his office not later than June 6.

St. Bride's Church, Kelvinside, Glasgow.—This church is to be lighted by electricity. The supply will be taken from the mains of the Kelvinside Electricity Company. This is the first church in the district to be lighted by electricity; the plans and specifications were drawn out by Mr. W. Elsdon Dew, resident engineer to the supply company, and the contract has been placed in the hands of Messrs. Claud Hamilton, Limited, Glasgow. Other churches in the district have been considering the advisability of keeping up with the times.

Windsor.—The Town Council have received a memorial with regard to the electric light. The Mayor, at a meeting last week, suggested that the memorial should be referred to the Electric Lighting Committee. The substance of the memorial was a request that the Council would urge matters on as quickly as possible with regard to the supply of the electric light. Councillor Reavell said it would be sufficient if the reference to it was seen in the newspapers' record of the meeting.

Edinburgh.—A deputation has been received by the Town Council on the subject of the recent order concerning the removal of overhanging signs and lamps. It was pointed out by one of the deputation that as they were about to get the electric light, and a great many traders intended to have arc lamps placed outside their business premises, it would be a very great hardship for them to go to the expense of £50 or £60 for lamps and then get an order afterwards for their removal.

Larne.—Mr. J. D. A. Norris, the receiver and manager of Messrs. J. H. Gordon and Co., Limited, electrical engineers, has acknowledged the receipt from the Town Commissioners of £112. 10s. on account of lighting the town to April last. The Commissioners have spent considerable time in going over the clauses contained in an agreement to be entered into with Messrs. J. H. Gordon and Co., Limited, for the lighting of the town for the ensuing three years. Several clauses which had been struck out or amended by the receiver and manager of Messrs. Gordon and Co., have been reinserted by order of the Commissioners.

Brighouse.—At a meeting of the Town Council, held under the chairmanship of the Mayor (Alderman William Smith), a letter has been read from Mr. George Furniss, solicitor, Brighouse, asking for the consent of the Corporation to the obtaining by a proposed local company of a provisional order to take over the plant of Mr. A. B. Brooke, Brighouse, and to supply electricity in the borough for lighting or other purposes. The Mayor proposed that the consent of the Corporation be withheld, and spoke strongly in favour of the Council taking the electric lighting of the borough into its own hands. Alderman Kershaw seconded this, and the motion was carried.

Cheltenham.—The borough surveyor has been authorised, as he required assistance in the electric light department, to employ an assistant at a cost not exceeding £20 per month, such assistant to hold office until the appointment of a permanent electrician at a commencing salary of £200 per annum, rising by annual instalments of £10 to £250. The surveyor has also been authorised to obtain 15,000 yards of tubing for carrying the electric cables, at a cost of 35s. 5d. per 100ft., from Mr. W. C. Hawtayne, of Victoria street, S.W. The Town Council have resolved to postpone the question of providing a gas-testing station till the question of providing an electric light testing station comes up for discussion.

Chagford and Devon Company.—The shareholders of the Chagford and Devon Electric Lighting Company met on Friday, Mr. Eaton presiding. The manager (Mr. G. H. Reed) reported that fresh applications for additional light were constantly being

Digitized by Google

received, and that the light continued to give satisfaction. The Company was now making satisfactory progress, and was expected shortly to be in a position to pay a dividend. Mr. Reeves, a director, stated that he had examined the works thoroughly, and, as a practical electrician, had pleasure in reporting that the works had been carried out and the cables laid in a manner highly creditable to Mr. Reed, and that the whole was now in a satisfactory condition.

Coventry.—At a recent meeting of the Town Council, the Electric Lighting Committee reported that Mr. Hammond and Mr. George Steane had attended the committee with plans and specification of the proposed electric lighting station, which were approved. It was ordered that advertisements for tenders should be inserted. The General Works Committee reported last week that at their meeting on the 1st inst. a letter was read from Mr. Graff Baker with respect to the tramways, asking that the question of giving notice to terminate the agreement of April 17, 1893, be postponed for a further period of one month. The committee ordered that the matter be postponed for one month from the 1st inst., and that Mr. Baker be informed that the committee cannot consent to the system of cross suspension in the Warwick-road.

Taunton.—Mr. Harold W. Cousens, the electrical engineer to the Taunton Town Council, reports that the staff have erected the small engine and alternator, and are working them regularly on Sundays, and during the hours of light load. No. 1 transformer sub-station is now in full working order, and there are 480 16-c.p. lamps connected to the low-tension cable. Steam has been raised in the boiler. All consumers on the incandescent circuits (save eight with an average of three lights each) are now charged by meter. During the past quarter 124 additional 16-c.p. lamps have been added to the mains. Mr. R. W. Phillips and Mr. E. B. Thornhill, assistant electricians, have received an increase in their salary of £15 per annum. Tenders for the supply of 1,500 tons of coal to be supplied during the ensuing year are to be advertised for.

Electric Lighting at Cardiff.—The Corporation Lighting Committee, who met on Tuesday, had before them a letter from Mr. W. H. Massey, the electrical engineer, reporting progress of the work in connection with the electric lighting of Cardiff. All the pipe-laying was finished, and the outside work would be finished as soon as Mr. Harpur could fix the exact position of a few refuges still to be made. All the machinery would soon be delivered. At the suggestion of Mr. J. M Gerhold, it was decided to advertise for four mechanical engineers to attend to the electric light plant. Mr. S. Brain asked when it was probable that the works would be opened. Mr. Fletcher (Mr. Massey's deputy) stated that they would be ready to supply the town about the middle of July. The Mayor stated that most of the profit of the undertaking would accrue from the lighting of business premises, and not from street-lighting. Alderman Jacobs said they had previously agreed that a pamphlet dealing with the advantages of lighting by electricity should be printed, and he suggested that such pamphlets be got out forthwith and distributed. The Mayor also asked if the time was not opportune to go into the charges for the supply of electric light It was decided to proceed with the arrangement of the pamphlet at once, and it was suggested that a scale of charges be embodied therein.

Buckingham.—The Lighting Committee of the Town Council have considered the following letter and tender sent in by Messrs. Parr and Gillies on the subject of electric lighting: "We have carefully considered the above matter, and beg to inform you that we are prepared to light the town either on the arc or an improved incandescent system. In the former, we propose to use 34 lamps of 1,200 c.p. nominal, distributed about the town in such position as we deem would give the best effect. The cost of this system would be £165 per annum. On the incandescent system, we suggest about 60 lamps, varying from 16 c.p. to 100 c.p., according to position. The cost of this system would be £145 per annum. We have experienced considerable difficulty in working out the best system, as there are several points in each scheme which would require to be discussed with you, and which might probably reduce the cost. In either case, all the lamps would be controlled from the central station, and have the same lighting hours. In the event of either scheme, or some modification thereof, being accepted, we should require a contract for a period of not less than five years. We would suggest that a committee be deputed to discuss the matter with us, when we shall be pleased to explain fully the plans and details of each scheme." The Town Council decided to adjourn the matter in order to enable the Lighting Committee to have an interview with Messrs. Parr and Gillies; and also to make enquiries from towns where paraffin-oil lamps are used for public lighting.

Ayr.—The Ayr Town Council have further considered the question of introducing the electric light into the burgh. An exhaustive and elaborate printed report, drawn up under the instruction of the Council by Mr. Hammond, was submitted, and the town clerk read a letter from Mr. A. F. Carmichael, on behalf of the Caledonian Electric Supply Company, Edinburgh, containing an offer to introduce an installation of the electric light under transfer of the rights of the Corporation contained in their provisional order obtained some years ago. A long discussion ensued. Mr. James Smith, convener of the Lighting Committee, moved, and Mr. Ure seconded, that the Council proceed with the installation of the electric light under the provisional order obtained several years ago. Mr. W. Beveridge moved, and Mr. W. Smith seconded, that a plebiscite of the inhabitants be taken on the question; Bailie Willcock moved, and Captain Galloway seconded, that the offer of the Caledonian Company or some other company should be considered, and overtures made to them by the Council. In the course of the discussion, Mr. W. Auld, a representative of the Third Ward, stated that he had taken a plebiscite of the ratepayers in that ward on the question, and the result was that he had found 75 per cent. of those who had voted were in favour of the introduction of the electric light. After divisions had been taken it was agreed to instruct Mr. Hammond to proceed with measures for the introduction of the electric light, and it was remitted to the Lighting Committee to act along with Mr. Hammond. It is estimated that the first cost of the installation will be about £15,000.

Lighting of Mills and Country Residences.—Messrs. John Davis and Son are engaged upon a large lighting and power plant for Messrs. F. Longdon and Co.'s mills in Derby, the number of lamps being over 500, of candle-powers varying from 8 to 32. There are motors of from ½ h.p. to 5 h.p. for working sewing machines, lifts, etc., and with a view to economy, a special change-over arrangement is fixed in the engine-house, so that should only a few lamps be required at any time in any part of the building, connection can be made to the Corporation supply mains without putting out the light even for a moment. The firm are also engaged on several complete plants for country residences. One completed at The Cedars, Breadsall, consists of an oil-engine, dynamo, a set of 53 accumulators, and switch-board, complete with regulating and starting switches, automatic safety fuses, alarms, etc. The oil used is paraffin, of the Royal Daylight brand; this is converted into a vapour by being pumped through a red-hot tube, then automatically mixed with a correct amount of air, and passed into the cylinder, where it is exploded in the same manner as coal gas is in the now well-known gas-engines. Every detail of the plant has been most carefully studied and designed for economy. Gas and oil engines being sometimes a little difficult to start, Messrs. John Davis and Son have overcome this difficulty by an arrangement on the switchboard, by means of which the current from the accumulators is made to drive the dynamo as a motor, and this in turn drives the engine until it has attained its speed, when it automatically takes up its work and charges the accumulators. There are nearly 100 lamps of various candle-power installed in the house. In this age of £ s. d. an idea of the cost of working such a plant may be interesting. From tests recently made it was found that the cost of the oil used in the engine was ½d. per horse-power per hour, and the cost of the light equal to gas at 2s. 6d. per 1,000 cubic feet, full allowance being made for the depreciation of the plant. Another point in connection with this plant is that by a single and ingenious contrivance the firm have almost entirely done away with the noise which is, as a rule, a disagreeable adjunct to all moving machinery. So far successful is this arrangement that within five yards of the engine-house neither smell nor noise is discernible. An almost identical plant is now being installed at the Duffield residence of Mr. Abraham Woodiwiss.

St. Pancras v. City Lighting.—Mr. H. H. Bridgman, in the course of a communication to the *City Press*, says: "A contemporary has called attention to a statement by Mr. Preece, the electrical adviser to the Commission, wherein he is represented as saying that the electric lighting in the City costs £27 per lamp, whilst in St. Pancras the cost is only £17 per lamp, and suggests by way of explanation that the City should have undertaken its own electric lighting the same as St. Pancras did, instead of allowing contractors to do it, and so reap all the benefit. I have not read the actual statement said to have been made by Mr. Preece, but as I consider him to be as discreet and accurate as he is capable as an electrician, I feel satisfied he would not have given utterance to such an expression without duly qualifying the same. In the first place, the contract price of the City lamps is not £27, but £26 each per annum, and the answer to the alleged statement as to the difference of cost per lamp will give a very different complexion to the subject; but for the fact, however, of the City electric light contractors having the private lighting of the City as well, the cost would not be so low as £26 per lamp. I happen to be a member of the St. Pancras Vestry as well as a Commissioner of Sewers, and I very much question the accuracy of the price named per lamp in St. Pancras. I have not the reports by me, but my impression is that the cost is very considerably higher than £17 per lamp. The figures given, however, are sufficient for my present purpose, as I may have to return to the subject again. In St. Pancras, 86 arc lamps displaced 479 gas lamps. In the City 479 arcs displaced 1,258 gas lamps, or, in other words, each arc lamp in St. Pancras displaced 5½ gas lamps, whilst in the City each arc displaced only 2⅝ gas lamps. This means that practically in the City the arcs are only half the distance apart that they are in St. Pancras. If therefore the number of lamps in St. Pancras were doubled, the cost of lighting would practically be doubled. The lamps I should say are the same nominal power—viz., 2,000 candles—both in the City and St. Pancras, whilst the distance between the gas lamps was about the same. Now a simple calculation will show that, distance for distance, the St. Pancras arc lamps compared with those of the City ought only to cost £13 per annum each, whereas £17 per lamp shows an excess in cost of 31 per cent. on the cost of the City lamps. I do not write with the slightest thought of disparaging St. Pancras. On the contrary, I think it says much for the pluck of the Vestry that they should be the first of the metropolitan parishes to embark in so bold an enterprise as to light the streets by their own installation; but personally I have always considered in this matter of electric lighting that it is rather beyond the province of the local authorities to risk the ratepayers' money in enterprises which must be largely experimental, whilst there are so many public

Digitized by Google

companies with private funds at their back to compete for the work of developing the principle of electric lighting. Monopolies are not created thereby, because there is ample provision made by Act of Parliament enabling local authorities to buy up the electric light companies on fair and equitable terms if purchase should be deemed desirable. This option is very important to public authorities. The public and private lighting of the City by electricity is a great work, and, including the cost of the sites of the generating stations, has involved an expenditure of very nearly a million capital (£972,000). This includes the erection of buildings, the equipment of the three stations, and the distribution, and provides for 515 arcs and 906 incandescent lamps of 200 watts each for the public lighting of the streets, as provided for in the contract with the Commissioners of Sewers, as well as for equipping the stations and providing plant for the supply and conversion of current for private lighting in accordance with detailed specifications and schedules of prices approved by the Commission, necessitating an output of 1,000 kilowatts for public and other arc lighting, and 12,100 for private lighting—in all 13,100 kilowatts; and the cost has worked out at £75 per kilowatt. The carrying out of the work, with the exception of the delay and inconvenience occasioned chiefly by the laying of the mains in such crowded thoroughfares in the City, has been, on the whole, considering the enormous amount of work done, very satisfactory; and this satisfaction, so far as the public lighting is concerned, is emphasised by the fact that the gas lamps are now being removed from all the main thoroughfares. The public lighting is practically perfect, the failures, if they can be so called, being infinitesimal, and in my humble opinion, taken as a whole, the action of the Commissioners of Sewers throughout has been so sensible and businesslike that if the entire business had to be now begun I do not see how they could much improve on the lines they have followed. The delay in the carrying out of the private lighting has been also, to a large extent, consequent on the difficulties of obtaining sites for the numerous transforming stations for regulating the supply, of which there are, I think, 42 equally distributed over the City, being in nearly every instance placed underground, involving necessarily great expense in construction and elaborate fitting. Now that the work is practically completed, I think the City may be congratulated that it has been entrusted to such an enterprising and energetic company."

PROVISIONAL PATENTS, 1894.

MAY 7.

8982. **Improvements in dynamo-electric machines.** Thomas Barnet Grant, 15, George-street, Mansion House, London.

MAY 8.

9117. **Improvements in and relating to electromagnetic tools.** Peter Jensen, 77, Chancery-lane, London. (G. Fonda, ——.) (Complete specification.)

9123. **Improvements in and relating to electric railways.** Hiram Stevens Maxim, 45, Southampton-buildings, Chancery lane, London.

9129. **Improvements in electrolysis.** Henry Blumenberg, jun., 4, South-street, Finsbury, London.

MAY 9.

9178. **An electrolytic meter for measuring electric currents.** Addison Goodyear Waterhouse, 33, Old Broad-street, London.

9184. **Improvements in conductors for the distribution of electrical energy and the insulation thereof.** George Wilkinson, 73, St. Stephen's-road, Upton Park, London.

9215. **Improvements in the system of circuit control for electric machines.** Charles Ervin Davis, 321, High Holborn, London. (Complete specification.)

MAY 10.

9285. **Improvements in or relating to electrodes and method of manufacturing the same.** Carl Kellner, 46, Lincoln's-inn-fields, London.

9292. **Improvements in or connected with electrolytic cells.** Edward Augustus Allen, 47, Lincoln's-inn-fields, London.

9295. **Improvements in electric lamps for bicycles and similar vehicles.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (George Mayr, United States.)

MAY 11.

9328. **An improvement in and relating to apparatus for electrolysis.** Benjamin Hooker, Pear Tree-court, Farringdon-road, London.

9342. **Improvements in the methods of electrically coating wire tubes and similar articles.** Richard Heathfield and William Stepney Rawson, 1, Leadenhall-street, London.

9348. **Improvements relating to electric lighting.** Alexander Wilson, 124, Chancery-lane, London.

9350. **Improvements in apparatus for electric lighting by means of primary or secondary batteries** Arthur Ford-Lloyd, 2, Phœnix-place, Mount Pleasant, London.

9351. **Improvements in apparatus for testing telephone lines.** Charles Herbert Elliot, Elmer's End, Beckenham, Kent.

9357. **Improvements in and relating to electric arc lamps and their construction.** Walter Rowbotham and Euphemia Rowbotham, Tintern Lodge, Upper Chorlton-road, Whalley Range, Manchester.

9362. **Electric alarm clocks with advertising spaces.** Samuel Sidney Bromhead, 97, Newgate-street, London. (Franklin Beuner, United States.) (Complete specification.)

9364. **An improved lubricant, chiefly designed for use on the collectors of dynamo-electric machines.** David Young, 11, Southampton-buildings, Chancery-lane, London. (Jacques Marius, Italy.)

9368. **Improvements in electric fuses.** Frank Brain, 1, Furnival-street, Holborn, London.

MAY 12.

9399. **A combination of the electric overhead trolley system and the electric accumulator system for railways and tramways.** Alfred Dickinson, Birmingham-road, Darlaston.

9410. **Improved means of gripping cords, wires, or the like, for electrical or other purposes.** Charles Henry Cutting, George Hawkins Ctuting, and Isabella Cutting, Imperial-chambers, Albert-street, Derby.

9437. **Improvements in the method of and apparatus for regulating the amount of light from electric glow lamps.** Henry Lea, 18, Southampton-buildings, Chancery-lane, London.

9456. **Improved junction or fuse box for electric wires.** Charles Newton Russell, 166, Fleet-street, London.

NOTES.

Newport (Mon.).—The site of the central station is in Canal-parade.

The Kinetoscope.—Mr. Edison is reported to be now completing this apparatus.

Telegraphy.—The telegraph line between China and Burmah will be completed this year.

Dover.—An exhibition of electrical apparatus has this week been held in the Connaught Hall.

Budapest Lighting.—Large extensions are to be made this year in the laying of electric light mains.

Electric Lighting in Gorlitz.—The local authorities have decided to introduce the electric light into the town.

A Car on Fire.—An electric car caught fire a short time ago in Brussels, but the flames were soon extinguished.

Calcutta.—The Calcutta Electric Lighting Bill and the Calcutta Tramways Act are being considered by the Indian Government.

Electric Clocks.—The journal *L'Electricien* of May 19 contains an illustrated description of the Cauderay system of clock regulation by electricity.

Central London Railway.—The Central London Railway (Extension of Time) Bill was read a third time in the House of Commons on Monday.

Karlowitz.—Messrs. Egger and Co. are fitting the palace of the Servian Patriarch with the electric light. There will be 200 incandescent lamps.

Wolverhampton.—As mentioned in another column, the Mayor of Wolverhampton laid the foundation-stone of the municipal electricity works on Monday.

Dear Gas.—At Moy, in Ireland, the price of gas averages about 8s. 6d. per thousand. There should be an opportunity here for a supply of electricity.

Concert.—The fourth of the series of concerts given in Belfast under the auspices of the National Telephone Company was given in the offices of the company last Friday.

The Solent.—The Royal Engineers have completed a system of electric search-lights for illuminating the Solent at night, thus affording protection against night attacks.

Jena.—Telephonic communication is to be established between Jena and Weimar, with connections with Erfurt, Gotha, Eisenach, Naumburg, Halle, Weissenfels, and Leipzig.

The Foreign Office.—The Foreign Office is being wired for the electric light, which will be switched on on the occasion of the official celebration of the Queen's birthday.

Another Eiffel Tower.—It is proposed to build an Eiffel tower outside Copenhagen. It will be lighted electrically, and it is possible that the lifts will be operated by electricity.

Transylvania.—Telephony is making considerable progress in Transylvania. A telephone system has been established between Klausenburg and Gyalu. Other extensions are in progress.

Electric Lighting in Krone.—A commission has been appointed by the Municipality to consider the question of lighting the town electrically. There is 300 h.p. of water power available.

Water Power.—The Société Lyonnaise des Forces du Rhone is about to commence operations in the carrying out of the undertaking for the utilisation of the waters of the Rhone for electric light and power purposes.

Newington.—The Local Government Board have sanctioned the loan of £33,000 for the erection by the Newington Vestry of baths and wash-houses, which, it will be remembered, are to be lighted by electricity.

Offenbach-on-the-Maine.—The municipal authorities are going to erect a small electric lighting station, the plant to be driven by gas-engines. The price for incandescent lamps per hour is to be 4pf., or, say, about ½d.

Award.—In connection with the recent distribution of prizes in the Glasgow and West of Scotland Technical College, Mr. J. Fred. Nielson has been awarded the Sir John Pender medal for excellence in electrical engineering.

Steam Traction in Paris.—A French contemporary in its current issue describes and illustrates the Serpollet system of steam traction for tramways, and which it is proposed to introduce in Paris in competition with the electric cars.

West Metropolitan Tramways.—The West Metropolitan Tramways will be put up to auction on the 13th prox. by Messrs. Edwin Fox and Bousfield. It will be remembered that it was on these lines that the Lineff system was to have been tested.

Electric Tramway at Nuremberg.—Messrs. Schuckert and Co. are preparing plans for an electric tramway between Nuremberg and Erlangen. The State railway system makes a long detour, but the tramway will be carried by a direct route.

Electric Power Pumping Station.—At Babolna, Hungary, a small electric power station is being erected in order to pump from a stream, about three-quarters of a mile distant, water for agricultural purposes. Messrs. Egger and Co. have the work in hand.

Newcastle Tramways.—The Newcastle Tramways Committee have again considered the question as to the best system to be adopted for the working of the tramways. A long conversation took place concerning the electric and cable systems, and it is reported that the general feeling seemed to favour the latter.

News by Telephone.—The account of the execution of the Anarchist Henry in Paris, which appeared in the evening papers on Monday, was sent to London by telephone. It was sent by the Central News, who often use the telephone for the transmission of important news from Paris. The telephone is dearer, but much quicker than the telegraph.

French Civil Engineers.—The members of the Société des Ingenieurs Civils de France will make their annual excursion this year to Belgium, commencing on July 15, and terminating on the 22nd idem. Visits will be paid to various works, and those intending to be present must acquaint the secretary by June 20, the offices being at 10, Cité Rougemont, Paris.

Electricity v. Gas.—Alderman Pollock, in bringing up on Tuesday the report of the Gas Committee to the Birmingham City Council, which showed a decrease of consumption of gas last year, said that it was evident that the competition of the electric light was seriously checking the consumption of gas, and that the application of electricity for illuminating purposes would grow.

Vienna Electric Tramways.—We have referred at various times to electric traction projects in Vienna, and now note that the *Zeitschrift für Elektrotechnik* of Vienna remarks that there is no scarcity of schemes, but that if the practical carrying out of the projects continues to go on as in the past, the Viennese public will be using the Wellner air-ship before they travel by an electric line.

Digitized by Google

Municipal Electric Lighting at Nuremberg.—The Municipality have decided that the central electric lighting station shall be erected outside the town at Tullnau. Mr. Oskar von Miller has been instructed to work out plans for an alternating-current scheme, and for alternating current transformed into continuous current.

Curtice's Newspaper Index.—A copy of the first volume relating to the quarter July-September has reached us. It is an index to practically everything published during that period in the *Times*, the London morning and evening papers, and in a number of weekly and provincial newspapers. The volume may be of use to public men, but to the majority of the community it does not appeal.

The Leipzig Electrical Exhibition.—The list of applications for space at the electrical exhibition which is to be held at the Crystal Palace, Leipzig, from June 8 to June 17 has now been closed. In spite of the short duration of the exhibition, and of people being tired of exhibitions, the show promises to be a very good one. Dr. Wiedemann has been elected president and Dr. Föppl vice-president of the exhibition.

Electric Colouring of Hides.—According to *Electricité*, a new process for colouring hides consists in spreading the skin on a metal table, covering all the surface with the exception of the edges with the colouring liquid, and passing an electric current between the liquid and the table. The effect of the current is, as in electric tanning, to open the pores of the hide, thus allowing the solution to penetrate better and to give a more durable colour.

A Convivial Gathering.—On the 5th and 6th June, just before the opening of the meetings of the Union of German Electrical Engineers, the third annual gathering will take place, at Leipzig, of the Freie Vereinigung der Vertreter von Elektricitätswerken. This society meets every year for the purpose of a convivial assembly, and for an interchange of opinions between the representatives of German electricity works. No papers are read at the meetings.

Electric Lighting at Mittewald.—A small but interesting central electricity station is being erected by Messrs. B. Egger and Co., of Vienna and Budapest, at Mittewald, near Villach, a favourite health resort. The various public buildings are to be lighted electrically from this station, and power is obtained from a high-pressure turbine working under a head of about 800ft. The turbine will be coupled direct to a dynamo running at 900 revolutions per minute.

Underground Railways in London.—We understand that no very decided step will be taken at present with regard to developing the various projects so far authorised for railways on the Greathead system, excepting only the Waterloo and City line. The extensions of the City and South London Railway are dependent mainly upon financial arrangements not yet completed, whilst the Central London Railway promoters are waiting to bring their scheme before the public for financial support at the most favourable opportunity.

Personal.—Mr. Graham Harris, Sir Frederick Bramwell's partner, has been asked by the Electric Lighting Committee of the Derby Town Council to deliver an address in connection with the electrical exhibition now being held in that town, and to which reference was made in our last issue. The lecture given by Sir Frederick Bramwell last week is reproduced in another part of the present issue. Mr. F. Uppenborn, who, we believe, is about to retire from the editorship of the *Elektrotechnische Zeitschrift*, has been appointed municipal electrical engineer to the city of Munich.

Search-Lights for Armoured Trains.—A new armoured train has been tested on a branch line between Newhaven and Seaford. Colonel Boxall, to whom credit is due for the new arrangement, considers that the ideal train is a battery of four or six heavy guns, mounted on two, three, or four trucks, with heavy armour plate, another truck with a powerful search-light and dynamo attached, which truck would follow immediately after the engine or be in front of it, and would, of course, be taken away with the engine before the battery was brought into action, and two or three coaches full of men, ammunition, stores, etc. An application which has been made for the search-light has not yet been granted.

The Hampstead Station.—Preparations have been for some time in progress, under the direction of the Hampstead Vestry, for lighting that suburb by means of electricity. The cost of plant for lighting the whole parish is estimated at £80,000, but at present provision is only being made for lighting the compulsory area under the provisional order obtained by the Vestry. The cost of the buildings now approaching completion is about £7,500, and that of the electrical plant for lighting the compulsory area is £19,794. Mr. Churchwarden Thwaites, chairman of the Vestry's Electric Lighting Committee, on Wednesday performed the ceremony of placing a memorial-stone in position at the new buildings in the presence of a number of the members of the Vestry and others interested in the undertaking.

Telephone Working and Electric Tramways. The subject of disturbances set up in telephone wires by the working of electric tramways is discussed by Messrs. O. E. Meyer and K. Mützel, in the *Elektrotechnische Zeitschrift* of May 17. The authors investigated the question as to whether the cause of disturbances in telephone wires is due to the overhead conductor or the return through the ground. They made a series of experiments in Breslau, and state that the noises heard in the telephones arose from the current induced therein from the trolley wire, due to the changes in the current strength in the conductor. The authors conclude that the earth currents contribute but little to the noises heard in the instruments, and they leave to practical men the provision of an effective insulator for telephone wires.

Thomas Parker, Limited.—In a recent issue we referred to the registration of this Company, and we now note that it is inviting subscriptions to shares. The capital of the Company is £75,000, divided into 7,500 shares of £10 each. Of these, 4,500 shares have already been taken up, and the balance of 3,000 shares has been offered for subscription. The Company has been formed to carry on the business of manufacturers of plant for electric lighting, electric transmission of power, electric railways, electric tramways, electro-chemical, electro-metallurgical, and other purposes. The vendor and promoter is Mr. Thomas Parker, founder and managing director of Elwell-Parker, Limited, and for five years works director and chief engineer of the Electric Construction Corporation. The directors of the Company are Messrs. C. Tertius Mander, J.P., Thomas Graham, J.P., William Thomas, and Thomas Parker, J.P.

Engineering Trade Section.—In the annual report of the London Chamber of Commerce reference is made to the proceedings of the Engineering Trade Section. The report states that this section, at its two meetings, discussed the desirability of effecting reforms in the present Patent Law procedure, and came to the conclusion that it was not expedient to attempt to bring about any alteration in the Patent Law as at present administered. On behalf of the

Digitized by Google

section, the council of the Chamber was requested to oppose the proposal embodied in Mr. Fenwick's Merchandise Marks Act Amendment Bill, which required the name of the manufacturer and the place of manufacture to be shown on all manufactured goods within the United Kingdom. Other subjects discussed included the Employers' Liability Bill and the discrepancy frequently found to exist between the specification and pattern in tenders for Government contracts.

Working Results of Electric Tramways.—The electric tramway constructed at Clermont-Ferrand, and which has been in operation for two or three years, was laid down by M. J. Claret, who has since transferred the line to the Compagnie des Tramways Electriques de Clermont-Ferrand. The report of this company, presented at a meeting on the 14th ult., states that the tramway legally passed into the hands of the company on December 13, 1893. The length of the line, which is served by 20 cars, is 4·34 miles, and it extends from Montferrand to Royat through Clermont, with a branch to the railway station. The number of passengers carried in 1893 was 2,492,483, the receipts amounted to £13,783, and the mileage run reached 259,062 miles. The increasing traffic has necessitated the provision of two new cars, which are to be delivered in July. The amount standing to the credit of profit and loss account was £3,875, out of which a dividend of £1 a share has been paid on the ordinary shares.

Conduit Systems in the United States.—Although the Metropolitan Traction Company would not part with the £10,000 prize it offered, it is reported that it has under consideration offers from two companies to lay down an underground conduit street railway, and that it has accepted the proposition of one of them. This is the Siemens-Halske Company, who have undertaken to put down an experimental line. The details of the system have been examined by engineers of the Traction Company, and, on the strength of their favourable report, a trial of it will be made on Lenox-avenue, where the company has recently obtained the right to lay lines upon an understanding with property owners that an underground conduit system would be used. Three miles of road altogether will be laid at the expense of the Siemens-Halske Company, and, if accepted, four miles more will be built at joint expense. The system proposed by the Siemens-Halske Company is the one that has been in use in Budapest.

The Paris Underground Electric Railway.—It appears that there is at last some hope of a definite decision being shortly arrived at concerning the projected electric railway in Paris from the Bois de Boulogne to the Bois de Vincennes. This railway, which is proposed to be carried out according to the designs of M. Berlier, who has already obtained a concession for its construction, is to form a complement of the metropolitan railway which has been discussed in Parisian circles for many years past. On Wednesday of last week, M. Jonnart, one of the French Ministers, attended before the French Railway Commission, in company with M. Colson, to furnish particulars regarding the proposed electric railway. At the same sitting the municipal engineers, councillors, and the promoter, M Berlier, gave evidence on the subject. The opinions of the General Council of the Bridges and Ways Department and of the municipal engineers was favourable to the scheme, which proposes a railway line carried in an iron tunnel 20ft. in diameter. The Chamber of Deputies is now on the point of deciding definitely on the scheme.

Niagara Falls Power Transmission.—The annual report of the Westinghouse Electric and Manufacturing Company contains the following statement: "The awarding to your company by the Cataract Construction Company of the contract for three 5,000-h.p. generators for the transmission of the power of Niagara Falls to Buffalo and other points was an event of more than ordinary importance. The officials of the Cataract Construction Company had employed the most renowned electrical engineers of the world, and had spent some years in a full investigation of the subject, and finally contracted with your company because of a belief in its ability to successfully carry out such an important undertaking. The transmission of power by means of these generators involves the use of your company's Tesla patents covering the system of multiphase motors, and therefore the successful starting of this plant cannot fail to have a great influence in the development by your company of other plants for the transmission of power from waterfalls to remote points, by reason of the experience gained in this instance, and by reason of the ownership of the controlling patents. The three generators contracted for will soon be completed and put in operation."

Measurement of Power in Three-Phase Circuits.—In discussing this subject in the columns of a German contemporary, Dr. O. Frölich deals with circuits grouped in the manner known as the link connection. If A B C are the currents in the three circuits, and P_1 P_2 P_3 the values of the absolute potential at the respective points where the power is delivered, he finds that the total power is given by the expression

$$W = A (P_1 - P_3) + B (P_2 - P_3),$$

or $$W = B (P_2 - P_1) + C (P_3 - P_1),$$

or $$W = C (P_3 - P_2) + A (P_1 - P_2).$$

If each of these three points be joined by a wire of resistance with a junction common to all, we obtain a star connection, and the sum of the currents in the three wires is zero.

$$i_\alpha + i_\beta + i_\gamma = 0.$$

Since $(i_\alpha - i_\beta)\, r = P_1 - P_2$, and similarly for the other circuits,

$$\frac{W}{r} = A\, i_\alpha + B\, i_\beta + C\, i_\gamma.$$

This formula shows how the total power is divided between the three circuits, and might be used to measure the power separately for each. For this purpose a wattmeter must be inserted in each circuit, the movable coil being traversed by the main current and the fixed coil by the current i. If the total power only has to be measured, a single instrument may be used, containing three fixed and three movable coils, the latter being, of course, fixed relatively to each other.

Union of German Electrical Engineers.—As we have already announced, the second annual meeting of the Verband der Elektrotechniker Deutschlands will be held at Leipzig on June 7, 8, and 9. The programme has now been issued. The following papers will be read: "The Scientific Electro-Chemistry of the Present Day and the Technical of the Future," by Dr. Ostwald; "Development and Position of English Electrical Engineering," by Mr. Gisbert Kapp; "The Nissl Main Telephone Exchange Switch," by Mr. F. Ross; "The Disturbances of the Physical Institute by Electric Tramways," by Dr. Budde (co-reporter with Dr. Wilhelm Kohlrausch); "The Control of Rotary-Current Plant and of Rotary-Current Direct-Current Transformers," by Mr. W. Lahmeyer; "Lead Safety Fuses," by Mr. Clarence P. Feldmann; "The Conductivity of Copper: Proposal for Introduction of a Standard System of Description," by Mr. J. Teichmüller; "Some Direct Indicating Electrical Measuring

Digitized by Google

Instruments," by Dr. Th. Bruger; "The Pressure and Current Curves of Various Types of Alternate-Current Machines, and their Influence on the Illuminating Power of Alternate-Current Lamps," by Dr. W. Wedding and Dr. G. Rössler; "Demonstration of Some New Galvanometers," by Dr. H. Du Bois; and "Continuous-Current Machine for the Three-Wire System," by Herr von Dolivo-Dobrowolski. Among the other business of the Union is the reception of a report from the committee on the introduction of standard sizes for contacts and screws.

Electric Transmission of Power in Italy.—Signor Boselli, the Italian Minister of Agriculture, Industry, and Commerce, has brought in a Bill for the regulation of the electric transmission of power over private property, and to which reference was made in a previous issue. Clause 1 provides that every proprietor shall allow overhead and underground conductors to pass over or through his property when carried out by any person who has temporary or permanent right to use the conductors for industrial purposes. Exceptions are made to this rule for houses (but the façades in public streets are not included), and the courtyards, gardens, and lawns attached to same. Clause 2 provides that those erecting conductors on private property shall carry out the work so that there is no danger. They can also be called upon to use any appliances which may have been erected by the proprietor for such purposes, to compensate him for the use of the same, and bear a proportion of the cost of maintenance. Clause 3 provides for conductors being carried across canals, aqueducts, and other works, provided no loss is caused to the owner. By Clause 4 it is provided that where public streets, rivers and roads are crossed, or where the façades of houses are used, the special regulations of local authorities must not be infringed. By Clause 5, those desirous of carrying conductors across private property must be able to state the value and advantage of the scheme, and that the route proposed is the most suitable. Clause 6 provides that before the work is carried out, the owner of the property shall be compensated for any depreciation which would be caused to his property. By Clause 7, for any system put up for less than nine years, the property is to be restored to its original condition. Clause 8 provides that the conductors must be carried out according to existing laws and correspond to the regulations in force with respect to telegraph and telephone traffic.

Electrically-Operated Pumps.—The question of combining centrifugal pumps with electric motors is discussed by M. J. A. Montpellier in *L'Electricien* of May 19, where illustrations are given of such combinations as laid down at the Altai mines by M. L. Dumont. The author points out that by arranging the pumps, as it were, in series, it is possible to lift water to a greater height than would otherwise be the case. For instance, the delivery-pipe of a pump at one level is connected to the suction-pipe of the second pump arranged at a higher level. In this manner it is possible to lift the water to a height double that obtainable with a single pump. The lifting work would be divided equally between the two pumps, provided, of course, that their speed is the same, a difficulty which is easily overcome by the use of electric motors. M. Montpellier says that by replacing the driving pulley by means of an electric motor, the two pumps can be directly coupled to the shaft of the motor, one being arranged on each side, and the speed of each being equal. Two pumps laid down in this manner and connected in series are at work at the Altai mines, where water is being lifted a height of 67ft. The delivery of this combination at a speed of 1,300 revolutions is 600 litres per minute. The electric motor driving the pumps takes 58 amperes at 110 volts. Another combination comprises four pumps, also arranged in series, at the same mines, where the lift of water is 148ft., and the quantity 300 litres per minute. This combination is driven by a motor consuming 80½ amperes at 115 volts. The author points out that centrifugal pumps can be operated equally well with a vertical as with a horizontal shaft, an arrangement which may frequently be found useful in mines. M. Dumont has carried out an installation of this kind, where a group of centrifugal pumps placed at the necessary depth are actuated by an electric motor arranged at the mouth of the shaft, and connected to the pumps by means of a vertical shaft.

The Electrical Trades Section.—The annual report of the London Chamber of Commerce states that during the past year the Electrical Trades Section and its committees held 12 meetings. The section has again had under its consideration the regulations of the Board of Trade on overhead wires. The Board have hitherto refused to modify these regulations, on the ground that they were drafted in consultation with the Institution of Electrical Engineers, and until alterations were recommended by that body they saw no reason to depart from the attitude already taken up. The report states further that it is satisfactory to record that the Institution of Electrical Engineers has now recognised that, looking to the commercial aspects of the industry, it is absolutely necessary that these regulations should be to some extent modified, and negotiations were in progress at the end of the year which it was believed would remove the disabilities from which the industry now suffers in this respect, consistently, of course, with a due regard for the public safety. Another question considered by the section during the year was the position of the electrical industry in reference to the telephone company's monopoly of the use of earth. Recognising that this position was a serious hindrance to the development of the traction industry, the section resolved upon the appointment of an electrical traction committee, which should have power to raise funds, engage counsel, and take such other steps as might be, in the opinion of the committee, necessary for the advocacy or propagation of traction interests. This committee was in due course constituted, and presented its case before the Joint Committee of the Houses of Lords and Commons on Electrical Power, with results entirely satisfactory to the traction industry. At the close of the year the Traction Committee were in communication with the Board of Trade as to the regulations under which the industry might be carried on consistently with the recommendations in the report of the Parliamentary Joint Committee already referred to. The section also directed its attention to the National Telephone Company's Powers Bill, railway rates on electrical goods, and the desirability of the promotion of lectures on the commercial aspects of the industry during the winter months.

A Water-Pail Forge.—Raising iron and steel to a welding heat by plunging it into a bucket of water is one of the more recent electrical accomplishments which has excited no end of interest and admiration. The phenomenon was illustrated experimentally to thousands of spectators at the Columbian Exposition last year, but instead of being simply an interesting scientific demonstration, as it was there regarded, it has latterly, according to *Cassier's Magazine*, been applied in a practical way as an every-day substitute for the time-honoured forge-fire. At the Edison Illuminating Company's Pearl-street station, at Brooklyn, N.Y., the "water-pail forge," as it has been aptly named, can be seen

Digitized by Google

in daily operation, and the practical value of its astonishing performances has there been demonstrated beyond all doubt. The apparatus there used consists in arranging across the top of an ordinary wooden water-bucket a bar of iron to which the negative pole of a dynamo is attached by a wire. The other pole of the machine is connected with a plate of copper in the bottom of the bucket. To bring the end of any desired bar of iron or steel to a welding heat, all that is necessary is to rest it against the bar across the top of the bucket and to dip the point into the water within. This closes the electric circuit, and in a few moments the end of the bar becomes hot enough to be readily worked under a blacksmith's hammer. What actually happens when the circuit is closed is this: the water in the bucket, under the action of the passing current, immediately begins to decompose into its component gases, oxygen and hydrogen, and the latter adheres in a film to the submerged part of the metal bar, protecting it from contact with the surrounding water. If now the electric current were not very strong it would cease to flow, because of the break in the circuit made by the hydrogen accumulation. With a sufficient strength of current, however, the resistance of the hydrogen envelope is overcome, and in doing this heat is developed—sufficient in this case to quickly bring the end of the bar to a white heat. That the water does not quench the bar is readily explained by the fact that the hydrogen film prevents the two from coming into actual contact. How great the possibilities of this water-pail forge are can easily be imagined. The ordinary forge and blower, and the necessarily attendant coal and smoke and dust, all are entirely dispensed with, and the whole outfit may be a likely feature of the ideal blacksmith's shop of the near future.

Electrical Sign Throwing.—In Trafalgar-square, on Saturday last, between the hours of 9 and 11 p.m., Captain Ronald A. Scott gave an exhibition of electric sign throwing by means of his patent electrical signalling projector. He selected for purposes of illustration the titles of a large number of newspapers, and when we arrived *Judy* was dancing, in letters about 6ft. long, and with an activity reminiscent of Lottie Collins, from Nelson's Column to the front of Morley's Hotel, and even flouting the sacred cupola which in an unobtrusive way relieves the stern outlines of the National Gallery. A little later we felt a guilty pleasure in seeing the *Electrical Engineer* executing a delirious fandango on the house-tops as if it had been to an Electro-Harmonic supper and found in the neighbourhood of Charing Cross the last straw which broke the back of its respectability. It was a new experience. The *Electrical Engineer* on the rampage. Inviting all London to "tread on the tail of its coat, bedad!" and conducting itself with a reckless disregard for the proprieties which was nothing less than shocking. At one moment it absorbed into itself, so to speak, the Hotel Métropole, reducing that palatial edifice to a mere hoarding for the display of its own entity. A second later and it blazed out on the front of Morley's, lit up the sombre elevation of the National Gallery, and cavorting madly the while made a probable bid for external space by soaring upwards and omitting to come down again. In these tactics it was succeeded by the *'Tiser*. We were not surprised at an exhibition of levity or of undue ambition on the part of the *'Tiser*, but when the *Morning Post* and the good old *Globe* so far forgot themselves as to urge on the same wild career, we thought it high time to step in to Messrs. Lombardi's reception-room, where Captain Scott was explaining his invention to a number of other journalists, and urge him to temper justice with mercy. Seriously, however, this method of advertising may be expected to find favour. The idea is not altogether new, but the means adopted by Captain Scott are as simple as they are effective. He uses a 15,000 c.p. to 20,000-c.p. projector of the usual pattern, fitted with a spherical reflector and cooled by a water-jacket. The designs to be thrown are in the form of stencil-plates and are placed one by one in a carrier fixed just behind the arc. Anything more striking than a poster of this kind, or the announcement of So-and-so's soap in gigantic letters of dazzling white light, it is difficult to conceive. For electioneering purposes also, Captain Scott's method should be extremely useful, while as the cost, in comparison to the result obtained, is moderate, electric sign showing will, no doubt, soon become popular among those who wish to call public attention to their wares.

The £10,000 Prize.—It appears that the competition opened by the Metropolitan Traction Company of New York for an improved system of electric traction to supersede the trolley method has turned out to be a fizzle. The following note, quoted from the New York *Electrical World*, throws some light on the matter: "In our last issue we referred to the passage of a Bill at the closing session of the Legislature on the subject of a prize for the inventor of the most economical street railway traction system. As predicted, the Bill, which has been signed by the Governor, is one authorising the State Railroad Commissioners to act as umpire in the alleged competition of the Metropolitan Traction Company. The Bill was signed on Wednesday of last week, and on Thursday the president of the Metropolitan Traction Company gave the following statement to the Press: 'Last fall we sent a letter to Messrs. Alfred C. Chapin, Michael Richard, and S. A. Beardsley, the State Railroad Commissioners, asking them to act as judges in a competition we proposed setting on foot. We offered a prize of 50,000dol. to any inventor who would offer an economical system of street railway traction which could be made available in this city, where the overhead system would not be permitted. The competition was to be open to all the world. We were flooded by letters from inventors. Between three and four thousand methods were sent us from all over. We could not wait for the Legislature to decide the question of the commissioners acting for us, however, and our offer had to be withdrawn.' In other words, several thousand American inventors were put to an expense which, in time and money, would amount to the value of the prize offered several times over by what, in the light of subsequent events, can only be denominated a sham competition. As remarked by us before, the time limit was so manifestly short that all who entered into the competition doubtless took it for granted that the company, which was presumably acting in good faith, would accord the necessary extension. The condition that the Railroad Commissioners should act as umpires was recognised by many as an impossible one in the absence of special legislation, but this was regarded, wrongly it now seems, as an oversight. The entire proceedings have an equivocal appearance, so much so, in fact, that it is probable that inventors who submitted plans will scrutinise with some interest the details of any system which the Traction Company may finally lay down. As to the Railroad Commissioners, it would be interesting to know in what light they regard the part which they have been made to play in the matter, particularly as their selection as umpires gave the appearance of good faith to the competition." Our contemporary's remarks, to say the least, are too mild for such a method of procedure on the part of the Metropolitan Traction Company.

THE EXETER ELECTRIC LIGHT STATION.

Although the supply station at Exeter has been in operation for some time, a short description of its chief engineering features, together with illustrations, should prove interesting at the present moment. The station is situated in New North-road, belongs to the Exeter Electric Light Company, Limited, and the supply of current, which was commenced in September, 1889, has steadily increased since that date. The incandescent lighting is on the high tension alternating system, whilst the arc lighting is arranged on the series system. The boiler plant at present fixed is as follows: three Babcock and Wilcox boilers giving 150 h.p. each at 150lb. pressure; the supply of water is obtained from the city mains through a Kennedy meter, the tank being capable of storing about 7,000 gallons. The feed is effected by means of a Worthington pump through a feed-water heater supplied by Messrs. John Fowler and Co., and two injectors furnish a reserve in case of accident to the pump. The steam before reaching the engines is passed through a Boys and Cunningham separator, which effectually prevents water from being carried over into the cylinders.

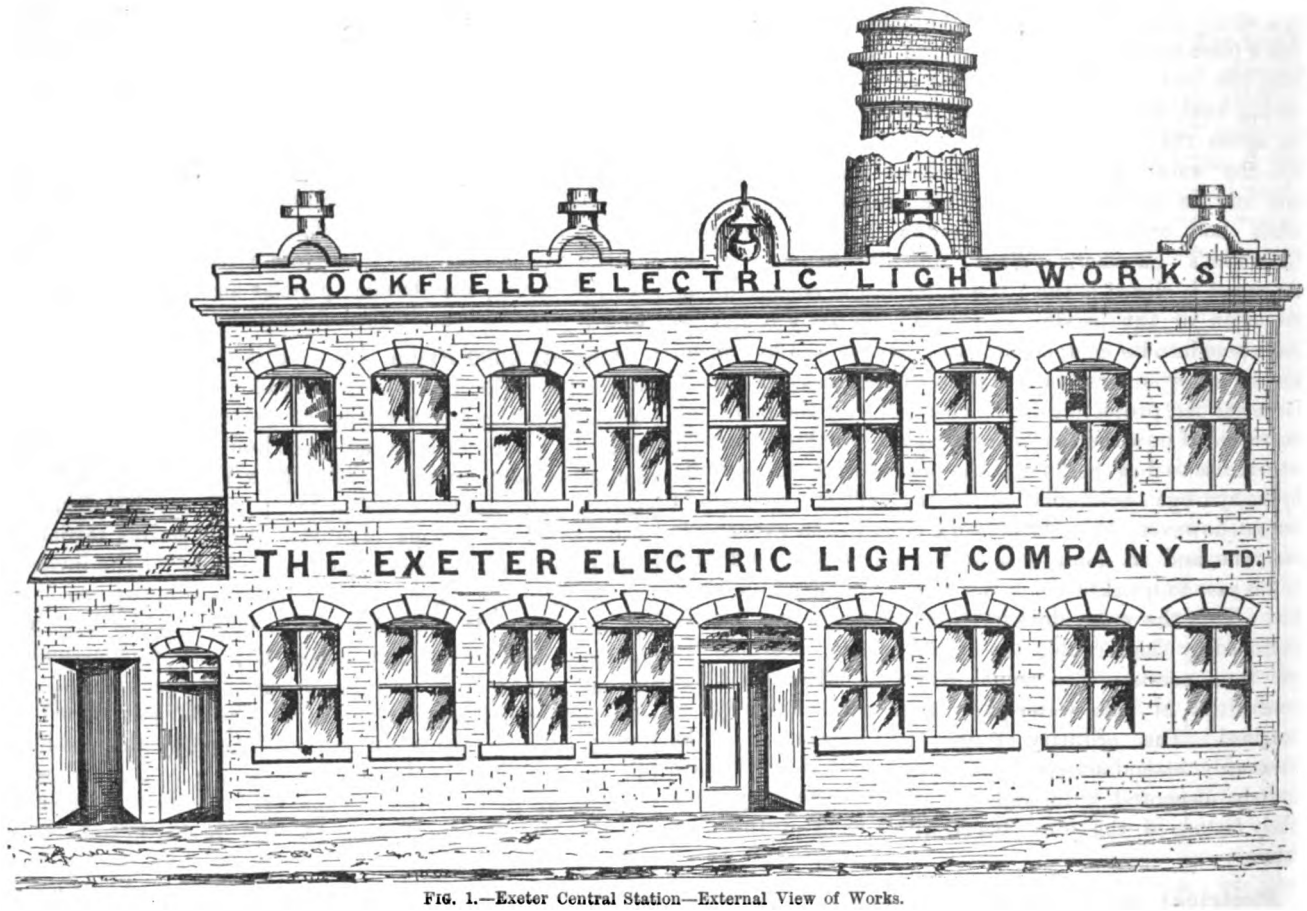

FIG. 1.—Exeter Central Station—External View of Works.

The engines comprise three horizontal compound engines by Messrs. John Fowler and Co., for the incandescent lighting; two of these are capable of developing 150 h.p. each, and the third 80 h.p. The two large engines have the high and low pressure sides on separate beds, but driving a common shaft with a flywheel between them. The small engine is on one bed with an overhung flywheel and outer bearing, and is provided with balanced valves. These engines drive by cotton ropes three Mordey

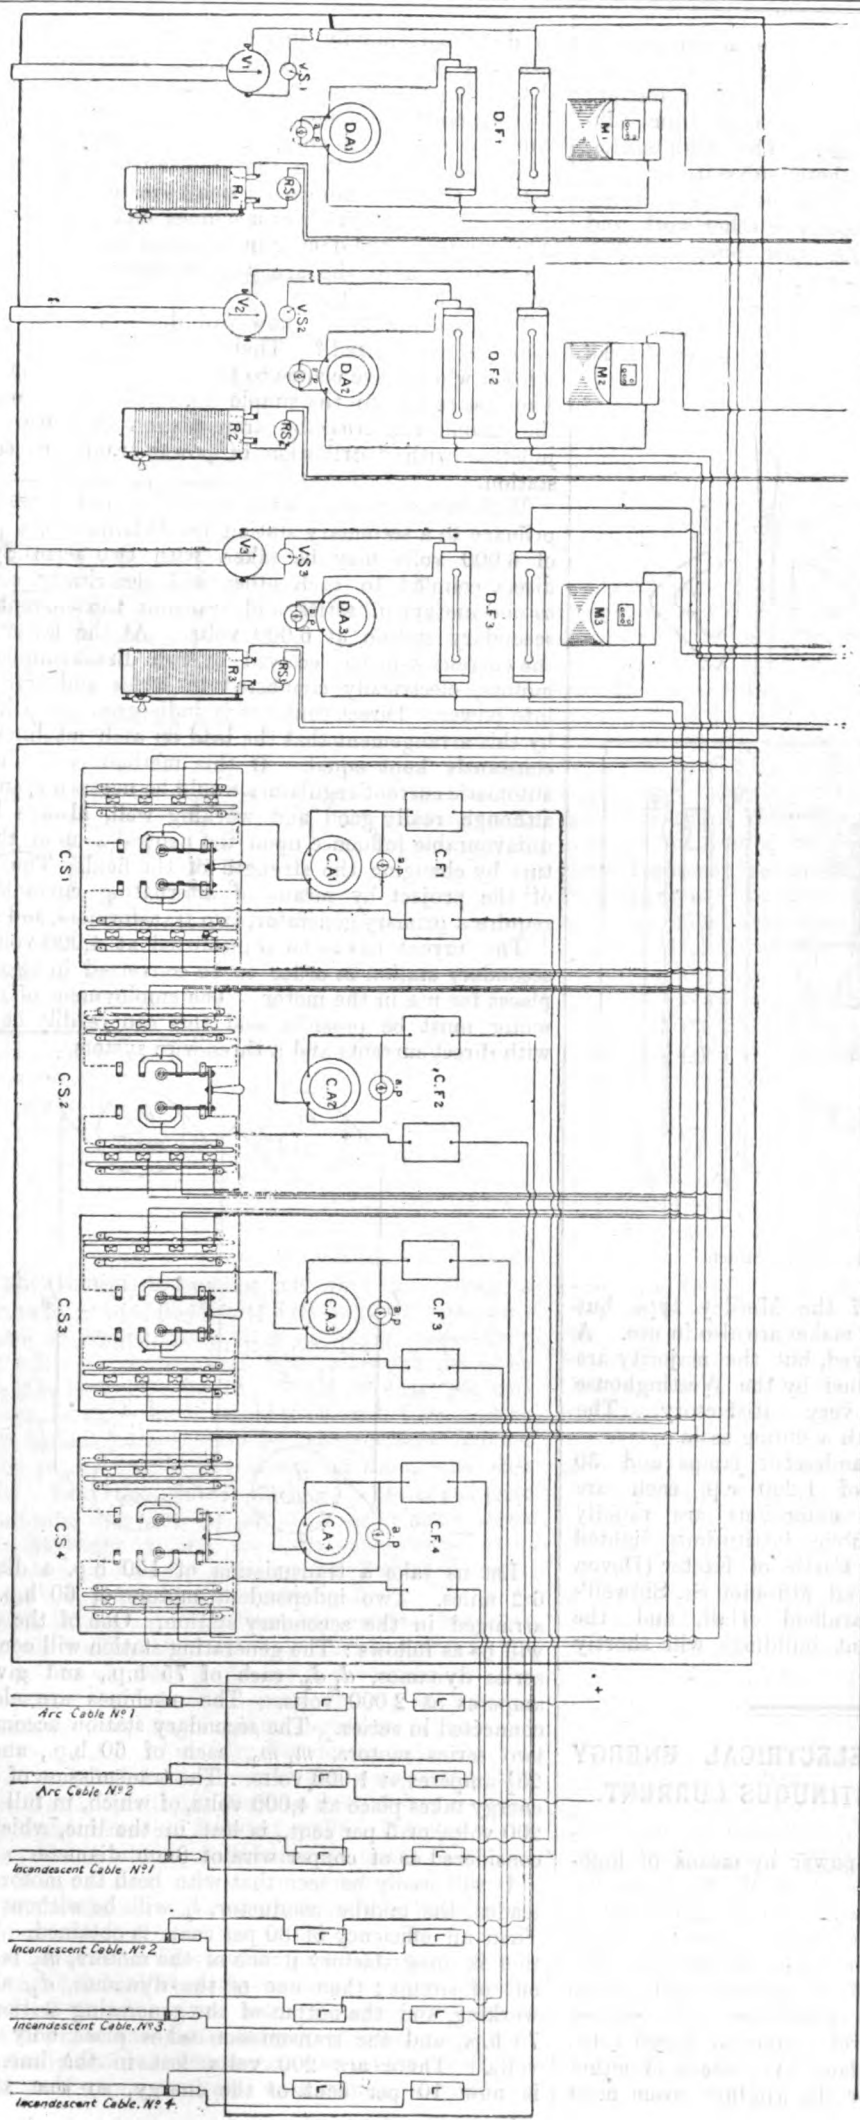

FIG. 8.—Exeter Central Station—Diagram of Dynamo, Circuit, and Test Boards.

alternators; two of the latter are of 75 units, and the other of 50 units capacity. The two larger machines have recently been fitted with new armatures of the latest type, having the two halves in parallel, with the addition of an "equaliser" to balance the output of each half. Each alternator drives its own exciter direct from its shaft by means of a claw coupling. The voltage is regulated by a resistance in the field of the exciter, which is shunt wound. This plant is used for the incandescent lighting.

There is also a series arc lighting plant, consisting of two vertical triple-expansion Westinghouse engines of the closed-in type by Messrs. Alley and McLellan, of Glasgow. These engines drive, by leather link belts, two 30-light arc dynamos of the Thomson-Houston type, supplied by Messrs. Laing, Wharton, and Down. These engines will develop 25 h.p. each at 500 revolutions, and their governing is almost perfect, especially when combined with the sensitive regulation of the Thomson-Houston controllers and regulators. A double-pole switch of special design is used to throw the load from one of these dynamos to the other.

On the switchboard each alternator is provided with double-pole long-break fuses, an Evershed ammeter, a Shallenberger meter to measure the output, a Cardew voltmeter with special transformer, and a hand regulator and switch for the exciter. The distributing or circuit switchboard was specially designed by the company s engineers, and made by Messrs. Newton, of Taunton. It comprises a main double-pole throw-over switch for each of the four main feeders, with arrangements by which any alternator may be connected independently with each circuit. These arrangements are made clear by the illustrations attached. In the diagram of the dynamo board, D F is the dynamo fuse; D A, the dynamo ammeter; *a p*, the ammeter short-circuiting plug; V, the voltmeter; *vs*, voltmeter switch; R, regulator resistance in shunt circuit of exciter; R S, regulator switch; and M, the meter. On the circuit board, C S is the circuit switch; C A, the circuit ammeter; and C F, the circuit fuse. At L on the test-board links are shown for testing purposes. The various circuits can thus be transferred from one machine to another with ease and without any perceptible variation in the light, and therefore parallel running

Digitized by Google

has not yet been found necessary. The mains for the alternating circuits comprise four main feeders, and two series circuits are carried from the station for arc lighting. Most of the distribution is now from sub-stations with low-tension networks. The high-tension cables are led in and out of these sub-stations, and breaking devices of special design are used to shut the current off from any section for repairs or other work, and the cables can also be looped for this purpose. The feeders, mains, and service lines (about 9½ miles in length) are of the Fowler-Waring concentric lead-covered and armoured type, differing only in the amount of insulation provided. It is intended to lay about 1½ miles of fresh mains this summer.

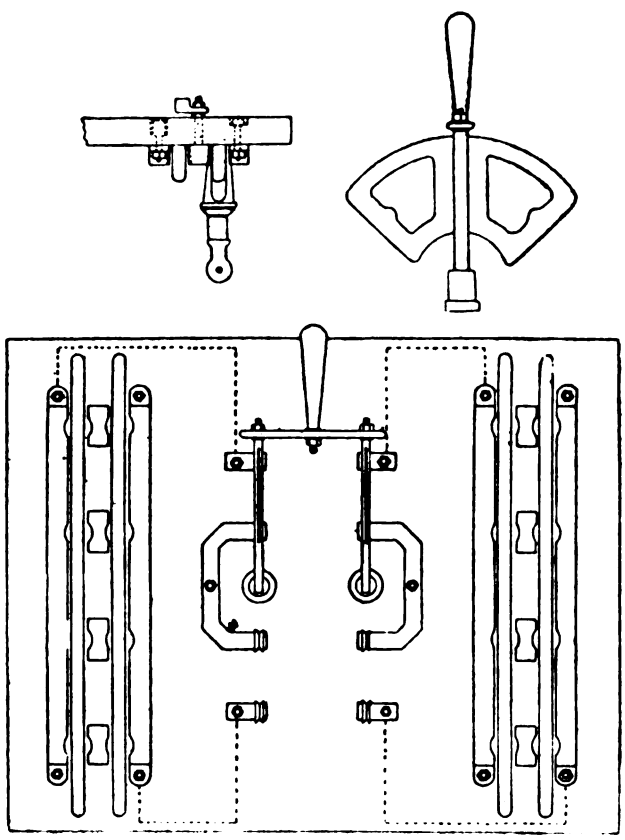

FIG. 4.—Main Double-Pole Throw-Over Switch.

The converters are mostly of the Mordey type, but "Hedgehogs" and a few of other makes are also in use. A few Thomson meters are employed, but the majority are of the Shallenberger type supplied by the Westinghouse Company, and have proved very satisfactory. The present charge is 6d. per unit with a sliding scale.

At present about 5,500 incandescent lamps and 30 Thomson-Houston arc lamps of 1,200 c.p. each are connected to the mains, and extensions are rapidly being made. Among the public institutions lighted throughout are: Theatre Royal, Castle of Exeter (Devon County Council), Albert Memorial Museum, St. Sidwell's Church and two chapels, Barnfield Hall, and the Athenæum; and other important buildings will shortly be connected.

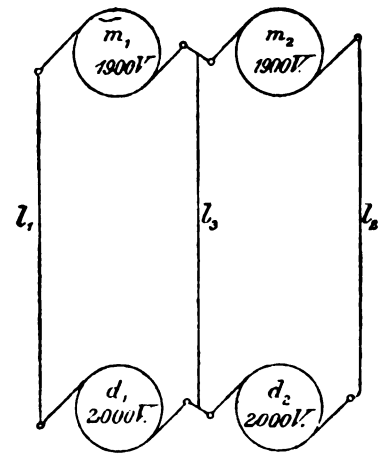
THE TRANSMISSION OF ELECTRICAL ENERGY BY HIGH-PRESSURE CONTINUOUS CURRENT.

The subject of transmitting power by means of high-tension direct currents is discussed by Mr. Ernst Schulz, of Aix-la-Chapelle, in the *Elektrotechnische Zeitschrift* of May 17. He points out that the danger of working high-tension continuous current machines and motors lies essentially in the winding of the field magnets and of the armature. Self-exciting shunt generators and motors cannot be well constructed for over a limit of 1,000 volts. By overstepping this limit the danger is present of either breaking down the shunt wire or the winding space must be disproportionately increased by the use of heavily-insulated wire. Thus from 1,000 volts we have been obliged to exclusively confine ourselves to series machines, in case preference is not given to special excitation of the shunt by low-tension current, as is necessary in the distribution of power. Both the primary and the secondary stations then contain each a small low-tension dynamo for this purpose. With series machines and specially excited shunt dynamos the danger in the shunt is avoided, although the insulation of the armature winding does not allow of exceeding 3,000 volts.

The question arises, how can direct current of 6,000 volts be transmitted? There are two cases to be considered which have claims to the execution of the scheme. The first relates to the simple transmission of power, and the second concerns the transmission of power in conjunction with distribution of power from the secondary station.

With regard to the simple transmission of power from a primary to a secondary station for distribution, a pressure of 6,000 volts may be taken with two series dynamos, direct coupled to each other and electrically connected to one another in series, and transmit the current to the secondary station at 6,000 volts. At the latter station the current will be received by two direct-coupled series motors, electrically connected in series and transformed into power. Direct coupling is indispensable, as it is only by this arrangement that the load on each machine can be constantly kept equal. If this method is not adopted, automatic current regulators would be necessary, and these, although really good and working well, always have an unfavourable influence upon the neutral zone of the armature by changing the strength of the field. The solution of the project by means of alternating currents would require a primary generator, two transformers, and a motor.

The current has to be transmitted at 4,000 volts to the secondary station in order to be converted in two distinct places for use in the motor. The employment of only one motor must be possible, and this can readily be effected with direct currents and a three-wire system.



Let us take a transmission of 150 h.p. a distance of 6·2 miles. Two independent motors of 60 h.p. will be arranged in the secondary station. One of the solutions will be as follows: The generating station will contain two series dynamos, d_1 d_2, each of 75 h.p., and giving 25½ amperes at 2,000 volts. The machines are electrically connected in series. The secondary station accommodates two series motors, m_1 m_2, each of 60 h.p., and giving 25½ amperes at 1,900 volts. The transmission of electrical energy takes place at 4,000 volts, of which, in full working, 200 volts, or 5 per cent., is lost in the line, which is here considered as of copper wire of 8mm. diameter.

It will easily be seen that with both the motors equally loaded, the middle conductor, l_3, will be without current. Then an efficiency of 80 per cent. is obtained. The position is unsatisfactory if one of the motors, m_2, is switched out of circuit; then one of the dynamos, d_2, also stops working, and the output of the generating station is only 75 h.p., and the transmission takes place only at 2,000 volts. There are 200 volts lost in the line, but this is now 10 per cent. of the energy, so that the motor

Digitized by Google

only receives 1,800 volts and 25½ amperes, and its output amounts only to 57 h.p. Moreover, the speed of the motor diminishes, but in practice the reduction in the efficiency of the motor is so insignificant that it may be neglected.

If the transmission is effected at 6,000 volts and 17 amperes, with a loss of 300 volts, or 5 per cent., in the line, the diameter of the conductors will be reduced to 5·2mm.; whilst a four-wire system would in many cases be practicable. The author has tested a three-wire system on the lines described.

MR. BARNES ON ELECTRIC RAILROADS.

BY FRANK B. LEA.

There is no small pleasure in reading the opinions and comments of a well-informed and unprejudiced railway man upon the question of employing electric energy for locomotive purposes, and one can hardly avoid such a feeling after the perusal of Mr. Barnes's notes respecting the use of electricity in heavy railroad service, as given in abstract form in the last issue of the *Electrical Engineer*. Mr. Barnes is a well-known authority throughout the United States upon all railroad topics, and whilst, of course—like all others in his position—his training and experience have been more particularly in the direction of steam locomotive work, yet he approaches the subject of electric equipments for railways in an unbiassed manner, which offers a strong contrast to the blind prejudice too often characteristic of railway officials against any new devices or improvements made available by the progress of invention.

The mere fact that a leading railway man should bring before the meeting of a railroad officials' club some speculations upon the possibilities of electric working for the heavy service of main lines—not to speak of its actually replacing steam locomotion—is in itself enough to show a disposition to discuss the matter fairly upon its merits, and not to dismiss the whole question with a wave of the hand as a visionary madness too much in the air for sensible men to entertain for a moment.

Whilst, however, speaking thus favourably of the tone characterising Mr. Barnes's remarks, and of the final conclusions which he draws, electrical engineers must not be contented with allowing his figures to pass without question, and as though they represented the utmost, or even average, powers of electrical working in railway service. Mr. Barnes is perhaps not very far wrong in taking the average consumption of fuel in good stationary engines and in steam locomotives as being respectively 1·8lb. and 4·2lb. per horse-power hour, although the latter is by no means too high a figure. What requires pointing out, however, is that these amounts of coal consumption refer to the *indicated* horse-power in the cylinders, and not at all to the actual brake horse-power at the driving axle on the line. Yet if Mr. Barnes deducts 15 per cent. up to the dynamo terminals, and 10 per cent. for electric waste on the line, he ought at least to make some reduction in the steam-locomotive efficiency as between indicated horse-power in the cylinder and the drawbar pull.

Even the much-abused Prof. Kennedy went so far as to give the steam locomotive a drawbar efficiency of only 80 per cent. of the cylinder indicated horse-power, and in average working 20 per cent. waste in engine friction, hauling dead-weight of engine, etc., would not prove a bit too much to assume. For Mr. Barnes to take the full efficiency of indicated horse-power in the steam locomotive is therefore hardly fair to the electric motor when instituting comparisons between drawbar pulls. Moreover, the percentages of loss which he gives for an electric line are higher than is actually shown by daily working. An efficiency at the electric generator terminals of 85 per cent. of the engine indicated horse-power has been exceeded in practice for some time now, whilst the line conductor is poorly arranged indeed when the loss thereon is as much as 10 per cent. of the energy put into it. Five per cent. is nearer the mark, as the South London and Liverpool lines have practically shown. The motor loss cannot with any attempt at satisfactory results be averaged, for obviously it must vary in a great degree with the character of the line and traffic.

But even with the three alterations thus proposed in Mr. Barnes's figures, a much more favourable result is secured for electric working. In the first place, the steam locomotive burns at least 5¼lb. per horse-power hour, reduced to drawbar pull, whilst on the electric line the corresponding coal consumption should not be more than about 3lb., full load being assumed in both cases. In one of his concluding paragraphs, however, Mr. Barnes puts the whole matter very neatly, the kernel of the nut being this: "The conditions which regulate the price (of fuel) control almost entirely the saving in fuel cost incident to the use of electric motors."

If a moral is to be found, let it be the following: "Look after your coal bill, and the dividends will look after themselves."

CONTINENTAL CENTRAL STATIONS.

Some statistics were given to the Berlin Electrotechnical Society on April 24 by Mr. F. Uppenborn. These statistics, which relate to central stations, were embodied in the first annual report of the Statistical Commission of that society, and Mr. Uppenborn, on behalf of the commission, read the report to the meeting. It appears that questions were sent out and 27 replies were received from the most important electricity works in Germany and abroad. We extract the following details from the report: If the central stations are classified according to the systems in use, five groups will be found. These are (1) direct current without the employment of accumulators; (2) continuous current in conjunction with batteries; (3) alternators with transformers and without a secondary distributing system; (4) alternators with transformers and a secondary network; (5) rotary current. The stations belonging to the first group comprise those of the Berlin Electricity Works, Elberfeld, Neuhaldensleben, and Traben-Trarbach. An accumulator sub-station has recently been erected in Berlin to serve a distant district, but this need not now be considered. The stations included in this group have a high efficiency of distribution. For instance, that of the Elberfeld works, measured between the terminals of the generators to the consumers' electricity meters is almost 99 per cent., the yearly loss being only 1 per cent., whilst many German gasworks experience a loss of between 10 and 22 per cent. of the total production. The stations included in the second group are those at Altona, Barmen, Darmstadt, Düsseldorf, Gablonz, s'Gravenhage, Gummersbach, Hagen, Hamburg, Mulhouse, Stettin, Stockholm, Vienna—Mariahilf. Of these electricity works, Düsseldorf, Gablonz, Gummersbach, and Stettin have battery sub-stations. The employment of accumulators necessitates particular electrical losses, but they have a satisfactory effect upon the working of the machines, and according to statistics and reports of the managements of the electricity works, their use brings about the highest utilisation of the fuel. The best result obtained is in the case of the Altona station, where a useful work of 4·13 hectowatt-hours was obtained from one kilogramme of fuel on an average for a year. This question is to be more fully discussed in the next report. The three-wire system is most generally used in the case of direct-current stations, the only exceptions being Hamburg, Hagen, and Gummersbach. With regard to the third group, the stations at Innsbrück, and of the International Electricity Company in Vienna, belong to this. The dispensing with a secondary distributing network increases the losses, but ensures greater security against disturbances in telephone wires. The fourth group includes the works at Burghausen and at Furstenfeld-Bruck, and the fifth solely the Lauffen-Heilbronn station. It will be seen that the direct-current stations are the most numerous. It must, however, be noted that the Cologne station and two small electricity works are not included in the statistics, and as a large station on the alternating system is being erected at Frankfort-on-the-Maine, one will be able to judge of the economy of the system on the basis of working experience. A large table is then given in which the electricity

works are grouped according to the population of the towns. The names of the towns are first given, the population and the number of lamps installed represented in hectowatts, together with detailed information.

ON THE MEASUREMENT OF THE RESISTANCE OF ELECTROLYTES.*

BY F. J. A. MCKITTRICK, PHYSICAL LABORATORY, DALHOUSIE COLLEGE, HALIFAX.

During the present session at Dalhousie College, I wished to make a series of experiments determining the electrical resistance of certain electrolytes. Not having the apparatus necessary for Kohlrausch's method at my disposal, I employed that used by Ewing and MacGregor (*Trans.* R. S. Edin., vol. xxvii., 1873, p. 51), which, according to the tests applied to it by Prof. MacGregor (*Trans.* R. S. Can., vol. viii., 1890, sec. iii., p. 49), seemed capable of giving results sufficiently accurate for my purpose.

Since this method, for its most successful application, especially if used in the way suggested by Prof. MacGregor in the latter of these two papers, requires some training of the eye in observing the motions of a spot of light, I undertook a series of preliminary experiments. In the course of these experiments, certain improvements suggested themselves to me. These improvements, and their effect on the working of the method, this paper attempts to point out.

As the above method has been fully described by Prof. MacGregor in the paper already referred to, I need give but a short sketch of it here. The electrolytic conductor is introduced by platinum electrodes as one of the arms of Wheatstone's bridge, and the process of determining its resistance is the same as in the case of a metallic conductor—viz., by a gradual adjustment of the arms. The indications of the galvanometer, however, will not be the same as in that case, owing to the fact that the electrodes become polarised through the passage of the current. The effect of this polarisation on the galvanometer is the same as if, during the passage of the current, the resistance of the electrolytic cell gradually increased.

Imagine the arms of the bridge so adjusted that, on the passage of the current, the light spot of the galvanometer moves off to the right and remains there, such a deflection having been ascertained to mean that the resistance being measured, if metallic, was too small to give zero deflection. If we gradually change the adjustment of the arms in such a way as to diminish this deflection to the right, it will not be found possible to obtain an adjustment making the deflection zero, but an adjustment will be reached with which the light spot moves first to the right, stops, moves back and off to the left, showing that though at the beginning of the flow of the current, the resistance of the cell was small enough to give a deflection to the right, it has been virtually increased by the polarisation until it is so large as to give a deflection to the left. We have thus a double deflection. As we continue changing the adjustment so as to diminish the initial deflection to the right, the double deflection will grow less and less, until finally we shall have only the deflection to the left.

If we had a magnet and mirror of indefinitely small moment of inertia, hung by a fibre offering no resistance to torsion, so that it would at any instant indicate the direction of the current flowing through it, this double deflection would only just vanish when the adjustment of the arms indicated the exact resistance of the cell—*i.e.*, when the resistance of the cell, calculated in the ordinary way from the resistances in the other arms, would be its exact resistance.

With an actual mirror and magnet of finite moment of inertia, no appreciable motion can be observed till the current has acted for some time. If the adjustment of the arms be such as to indicate a resistance for the cell only slightly greater than its real value, the first current flowing through the galvanometer will be very weak, and, before it will have had time to produce an appreciable deflection of the mirror, the electrodes will have become polarised, and our only deflection will be one to the left. If, then, we take the resistance of the cell to be that indicated when the double deflection has just vanished, we make an error, and conclude the resistance to be greater than it really is. Whether, with any magnet and mirror yet manufactured, this error can be made small enough to be neglected, can be determined only by experiment. In their experiments, Ewing and MacGregor assumed that the light mirror and magnets of Lord Kelvin's dead-beat galvanometer would give a close approximation to accurate results. In order to reduce polarisation, they used as current generator only one Grove cell, and introduced large resistances into the arms of the bridge. Their determinations, however, when compared with those given by more elaborate and accurate methods, were found to be too large, differing from Kohlrausch's, in some cases by as much as 12 per cent.

As their experiments were made when they were students and had acquired little experience in experimental work, the discrepancy may have been due to other causes than the defects of the method. Hence Prof. MacGregor, in order to test the method, made a series of experiments described in the paper cited above, comparing the resistances of solutions of zinc sulphate as given by this method and by the use of non-polarisable electrodes. To reduce polarisation he also used weak currents and, in addition, electrodes of large area. He found that if the mere vanishing of the double deflection were taken as the test of adjustment, the resistances determined would be too much greater than their real values to be regarded as a sufficiently close approximation. He noticed, however, that when he could no longer observe a double deflection, he yet could notice a distinct hesitation at the beginning of the single deflection. That this should be so is evident. For, after the double deflection has just vanished, the first current passing through the galvanometer still tends to cause a deflection to the right, but is overpowered by the polarisation current. Hence the mirror does not begin to move as soon as contact is made, but for a short time remains at rest. Clearly, then, if the adjustment of the arms be changed until we can observe not only no double deflection, but also no hesitation, we shall get more nearly accurate results. By observing the vanishing of the hesitation, Prof. MacGregor was able to get results which, in the case of high resistances, differed from their true values only by from 0·1 to 0·4 per cent.

I began, therefore, by endeavouring to observe the vanishing of this hesitation, testing my results in the same way as Prof. MacGregor had done in the paper cited above. The electrolytic cell which I used consisted of strips of window glass cemented together with marine glue. Its length was about 16cm., breadth 8cm., depth 9cm. It was divided transversely into two equal compartments by a glass partition cemented in so as to be watertight. Passing through the centre of this partition, and cemented at right angles to it, was a glass tube with its ends open. Its length was 1cm., the diameter of its bore 0·3cm. At each end of the box I placed my platinum or amalgamated zinc electrodes, as the case might be. They were each about 7cm. square, and had narrow strips projecting above the box. To these strips of the zinc electrodes thick copper wires had been soldered without the use of acid; to the platinum electrodes, thick platinum wires had been welded. By these wires the cell could be joined up as an arm of the bridge. The electrodes were, in all cases, placed as close as possible to the ends of the box. Since, however, the resistance of the column of liquid in the tube was about 1,000 times that of a cross-section 1cm. in length of the liquid in the box, slight differences in placing the electrodes made no appreciable difference in the resistance of the box. The part of the box above the surface of the liquid (especially that of the glass partition) was kept clean and dry, and during the experiments, except where the narrow strips of the electrodes projected upwards, the box was kept covered.

With this cell (1) it was the same liquid, whose resistance was measured whether the platinum or zinc electrodes were used, and (2) the tube being in the centre of a large mass of liquid, that liquid being approximately at the temperature of the laboratory, and the time intervening between two measurements—one by the platinum the other by zinc electrodes—being small, any change in the resistance

* From the *Transactions* of the Nova Scotian Institute of Science.

Digitized by Google

due to change in temperature might be neglected. The box of resistance coils used was a small one. The coils were arranged so as to form three arms of a Wheatstone's bridge. Two of them contained two coils each, 10 and 100 Siemens units respectively. The third contained a number of coils ranging from 500 to 1 Siemens units, together with a rheochord for measuring fractions of a unit. The coils had been accurately calibrated in legal ohms by White, of Glasgow. The galvanometer used was a "dead-beat" one of Lord Kelvin's, having a resistance of 400 ohms. The mirror, with magnets attached, weighed 0·035 gramme. For making and breaking contact I used a "rocker," like that described by Ewing and MacGregor in the paper referred to above. It was so designed that the battery wire was joined up a small fraction of a second before that of the galvanometer.

I found that I was unable with any certainty to detect the vanishing of the hesitation. To my eye it did not seem to vanish even when the adjustment of the arms indicated less than the actual resistance of the cell. The motions of the magnet certainly became quicker then, but none the less did I think I could detect a hesitation. Nor is this other than we would expect. The current must always act for a certain time before any appreciable motion of the mirror occurs. The length of this time will vary with the strength of the current. With a weak current the magnet always starts slowly, while with a strong current it may seem to start almost instantaneously. With a certain current and a certain resistance of our cell, there will be a particular hesitation corresponding to the adjustment of the arms indicating the exact resistance of the cell. With considerable practice we may train the eye to recognise this particular hesitation, so that, within a short range of this resistance of the cell, we may be able to make almost perfect measurements. This was the only way in which I was able to use Prof. MacGregor's method, and the result was unsatisfactory. For when the resistance of the cell was changed to any extent, the strength of the current changed and I found that my familar hesitation was no longer that which corresponded to the adjustment of the arms indicating the resistance of the cell.

In my experiments I noticed, however, what is clearly evident, that the stronger the currents the greater was my double deflection, that if, for certain resistances of the arms, with a certain current I could get a double deflection, then with a stronger current I would get a larger deflection, and, what to me was more important, if, in the former case, the double deflection had just vanished, in the latter case it was distinctly visible. I immediately tried still stronger currents, and found that in every case the stronger the current the nearer would be the adjustment of the arms, when the double deflection had just vanished, indicate the true resistance of the cell. It appeared, therefore, that I had merely to increase the strength of the current to make my error as small as I pleased. In attempting, this, however, difficulties arose:

1. As the battery current was increased, so was the polarisation current. To lessen this, my electrodes were made as large as possible. As I have stated above, they were about 7cm. square. I might have platinised them, after the manner of Kohlrausch; but as the method under consideration, owing to the simplicity of apparatus required, is especially useful for measuring resistances of electrolytes in ordinary laboratory work, I was more interested in knowing what degree of accuracy was attainable by it with apparatus which is always at hand.

2. Since the motions of the mirror are indicated by those of the spot of light reflected from it to a screen, in proportion as the double deflection gets smaller and smaller, the difficulty in observing it gets greater and greater. Especially is this so if the current be strong, for then the motions of the spot become so rapid that, unless the double deflection is distinctly made, we are not able to observe it. This difficulty I completely removed by placing a rectangular sheet of zinc 3in. or 4in. in front of, and hiding from my eye, the left side of the screen. It was easy to place this so that, on looking past its right edge, I could just see the faintest glimmer of the spot of light. Since I always sent the current in such a direction that the double deflection was to the right, it is evident that even the least tremble of the spot to the right could be at once observed. More especially was this so, as the sheet of zinc was much nearer to the spot of light than to my eye. It is necessary, of course, that the edge of the spot of light that we are observing should be very clearly defined, and that no motion of the head should be made at the instant of observation.

3. With strong currents electrolysis of the solution goes on at a rapid rate, and, again, there is danger of the coils becoming heated. During the final measurements, then, when we are using the strongest currents, contact in the battery wire must last only for a small fraction of a second. The "rocker" thus became too slow a means of making and breaking contact. By joining up the galvanometer first and by a separate key (a method to be justified later) the solution of this difficulty became easy, for then we have only to make and break contact rapidly in the one wire. This I accomplished by slightly flattening a piece of thick copper wire, and sinking it into a board till its flattened surface was only slightly above that of the board. This wire I connected with one of the battery wires. The end of the other battery wire I flattened, and by simply drawing it over the board and across the wire, contact could be made and broken as rapidly as desired.

I found it quite impossible, as did Ewing and MacGregor, and Prof. MacGregor, to obtain platinum electrodes which in themselves did not constitute a voltaic cell. In every case my electrolytic cell was found to be a voltaic cell with a small, and, apart from polarisation, practically constant E.M.F. It is evident that with this method the adjustment of the arms which would give no double deflection would not be exactly the same as if the electrolytic cell were not behaving as a voltaic cell.

Both Ewing and MacGregor and Prof. MacGregor overcame this difficulty in this way. Call e the E.M.F. of the cell. Pass a current through the cell in such a direction as to produce a polarisation current greater than and opposite in direction to that produced by e. Then, as this polarisation slowly dies away, there will be a short time during which it will neutralise e. During that time they considered that the test could be made without error due to e.

To this procedure there are objections. In order to produce the necessary polarisation so that it will die away slowly, the current must pass for a certain time, and thus a certain amount of electrolysis goes on—the more, the stronger the current. Then there is the great difficulty in making the test at the instant at which e is exactly neutralised. In my very many trials I am not certain that I succeeded in making one test with which I was perfectly satisfied. In any case we do not entirely eliminate error due to e. For we have neutralised e only by covering our electrodes with gas, which must make the resistance of our cell appear greater than it really is. Since, however, e can always be made very small, this error is in practice negligible.

In his paper Prof. MacGregor pointed out one result of which he made no use, but which suggested to me an easier solution of this difficulty. What he showed was, in effect, that if the galvanometer wire be joined up first and the spot of light be allowed to take up a new position due to e, and if the adjustment of the arms corresponds to the exact resistance of the cell, then, on making contact in the battery wire, the current through the galvanometer due to e will remain unaltered. It seems reasonable to suppose, therefore, that if the adjustment of the arms nearly corresponds to the exact resistance of the cell, and if e be very small, then under these circumstances any change in the current due to e flowing through the galvanometer, which occurs when contact is made in the battery wire, will be very small. If, then, we should join up the galvanometer wire first, and make our measurements as if e had the value zero, would the error be negligible? To test this, I simply made several measurements, first by this method, and then be neutralising e. I varied both the size and the direction of e, but in no case was I able to notice any difference in the two measurements.

To proceed in this way, however, the galvanometer must be joined up first. Rigorously this will not give accurate results; for the principle on which measurement of resist

Digitized by Google

ances by Wheatstone's bridge rests, requires that the current shall have attained a steady value. Whether, practically, with circuits such as I was using, any error would be introduced by this method could be decided only by experiment. To test this I simply measured the resistance of a solution of zinc sulphate, using amalgamated zinc electrodes, first joining up the battery wire before the galvanometer wire, and then *vice versâ*. The experiments that I made perfectly satisfied me that the error, if there was one at all, was clearly negligible.

During my experiments the resistance of my cell varied from 100 to 10,000 legal ohms. The accuracy with which I could determine the resistance is shown in the following table, which gives a few average results :

No. of Grove's cells used.	Resistance as determined by— Amal. Zn. electrodes.	Pt. electrodes.	Error. %
1.	6360 legal ohms	6430 legal ohms	1·1
2.	6360 ,,	6420 ,,	·94
3.	6360 ,,	6407 ,,	·74
8. Of low internal resistance	177·3 ,,	178·2 ,,	·51
,,	634·9 ,,	637·8 ,,	·46
,,	1893 ,,	1900 ,,	·37
,,	4585 ,,	4595 ,,	·22
,,	7439 ,,	7450 ,,	·15
,,	9139 ,,	9151 ,,	·13

As stated above, Prof. MacGregor's error in the measurements of high resistances varied from 0·1 to 0·4 per cent. With low resistances, however, his error was as great as 6 or 7 per cent. The first three entries of the above table show, then, that, with a comparatively weak battery as current generator, the errors in the resistances determined by employing the vanishing of the double deflection as test of adjustment, are comparatively large, considerably larger than they would be according to Prof. MacGregor's experience, if the vanishing of the hesitation were taken as the test. The last seven show that, with a strong current, the employment of the vanishing of the double deflection as test of adjustment gives results which in the case of high resistances are considerably more accurate, and in the case of low resistances very much more accurate than those given by a weak battery with the vanishing of the hesitation as test.

It would thus appear that the above modifications render this method capable of measuring all resistances with increased accuracy and low resistances with greatly increased accuracy, while they render it also capable of application without any previous training of the eye, and diminish very materially the time required for its application. The error in the measurement of high resistances is still greater than that of Kohlrausch's method—viz., 0·05 per cent. The only mirror, however, which was available for my experiments, though it weighed but 0·035 gramme, was much heavier than some which I believe are now manufactured. With a lighter mirror the inevitable error would doubtless be still further diminished.

GAS VERSUS STEAM ENGINES.

A paper was read before the recent meeting of the Incorporated Institution of Gas Engineers by Mr. Bryan Donkin on "Motors for Lighting or Generator Gas *v.* Engines with Saturated or Superheated Steam." We quote the following from the paper :

The figures contained in the following table have been taken from Prof. Witz's report, and they have been rearranged and put into the present form by the author :

Cost per Day of 10 Hours for Steam and Gas Engines with about 76 B.H.P.

(As given by Prof. Witz.)

Steam.				Gas.			
Depreciation, repairs, and interest.....	£0	13	6	Depreciation, repairs, and interest..	£0	13	6
Welsh coal, 2·6lb. per b.h.p. for 10 hours, at 23s. per ton	1	0	0	1·34lb. per b.h.p.	0	12	0
Oil and grease	0	1	3	Oil and grease	0	2	0
Driver	0	5	0	Driver	0	5	0
				Battery, etc.	0	0	4
Total.....	£1	19	9	Total..... ...	£1	12	10

But he cannot altogether agree with these figures, as, with a more economical steam-engine of the best type, only 1¼lb. of best coal per brake horse-power would be sufficient at a moderate speed and steam pressure, or a difference for 10 hours' work of 6s. 11d. per day in favour of gas, or, say, £100 a year taking 300 days. This is the calculated saving for these particular motors, exclusive of getting up steam or gas, and during gas trials at constant full load.

With this latter consumption the cost per day with steam and gas would be about the same. But then it may be said that the best large modern gas-engines, with generator gas, would only require about 1lb. to 1¼lb. of good fuel; so that the above proportion would not probably be altered materially. Much will depend on the price of fuel in the particular town under consideration. Mr. Dowson has done much, and was the first to make and introduce cheap generator gas, and to bring its advantages well before the public. He has written several excellent papers comparing steam and gas engines. A few extracts from trials, etc., from his last paper at the Institution of Civil Engineers are here given. According to Mr. Dowson, gas-engines for electric lighting, developing about 7,000 h.p., have been sold in England, and "Otto" engines for 11,000 h.p. in Germany. Doubtless the majority of these work with town gas. Messrs. Crossley say the number of "Otto" gas-engines in use in England is now about 20,000, and we may assume, perhaps, nearly double this number for all kinds of gas-engines. To give the best economy, a gas-engine should be worked at full load. There are no high-power gas-engines for electric supply stations yet working in England or in large cities on the Continent, all the existing central stations using steam. In London, mostly quickly-running compound and triple Willans engines are employed; but there are also other types, chiefly non-condensing. Mr. Dowson advocates the use of gas motors and generator gas instead of steam for central electric stations. A Dowson gas-generator usually consists of a small steam-boiler giving superheated steam, a generator, a cooler, a sawdust scrubber, and a holder. The gas passes through water twice, and finally through the coke and sawdust. For an 80-b.h.p. plant, the cost erected is about £325; for 530 h.p., about £1,100. At "Chateau Say," with 650 incandescent lamps, an "Otto" engine, with Dowson gas, consumed 1·2lb. of fuel per indicated horse-power hour. At the Chelsea Flour Mill, a 60 nominal horse-power twin-cylinder gas motor, with Dowson gas, 17in. diameter and 2ft. stroke, going at 156 revolutions, and giving 118 i.h.p., has been about two years at work. The amount of anthracite and coke used during a constant full load test was about 0·87lb. per indicated horse-power per hour. The governing is said to be satisfactory, and the cost of wages and lubrication is about the same as with a steam-engine. The gas consumption is 63ft. per indicated horse-power per hour.

The following is taken from the recent and very interesting Howard lectures of Prof. W. C. Unwin, F.R.S., at the Society of Arts, on the "Development and Transmission of Power": Many of the disadvantages of solid fuel are diminished by employing coal to produce gas, and using it in internal furnaces or gas-engines. Gas motors work with a higher thermal efficiency than steam-engines. The cost of ordinary lighting gas is increased, both by the need of a large generating plant to meet the great fluctuations in the demand for lighting and heating, and by the large distributing charge involved in supplying a great number of small consumers. If gas were made especially for heating and power purposes, either coal, water, or producer gas could probably be distributed to power users at less than half the present price of coal gas. From test trials made on a large pumping-engine of the London Hydraulic Power Company, the consumption was 2·2lb. of coal per indicated horse-power hour, but in ordinary intermittent work it is one-third more. This includes keeping the boilers hot, getting up steam, stoppages and starting of the engine, and with very different loads by day and by night.

Prof. Kennedy says that, at half load, the consumption with gas or steam engines per brake horse-power hour is about 40 per cent. more than at full load. It was mainly here that the loss in the engine due to "load-factor" comes in. A steam-boiler does its best at half to three-quarter

Digitized by Google

power; and at quarter power it works very wastefully. When a boiler is only kept hot, but not supplying steam, it may be called the "stand-by" loss. The professor adds that, from his experiments with boilers, by shutting down the stop-valve, he reduced this loss to 10 per cent.; or the consumption of fuel in a boiler not making steam was about 10 per cent. of the whole consumption. In case of fog, in electric stations or in large gas-works, it is often necessary to keep up steam, so as to be ready for an engine start at any moment. Prof. Kennedy uses in the electric supply stations under his charge non-condensing engines, giving on test trials 24lb. of steam per electric horse-power = 32lb. of steam per unit. His boilers give 11lb. of steam per pound of good coal, and 9⅓lb. reach the engine during a test. This works out to 3·4lb. of coal per electric unit delivered on a test. Instead of this, the actual figures for three to four weeks gave 5·3lb. This important difference between a test trial and several weeks' run is due to all losses at the station; keeping boilers and pipes under steam, and engines running at different loads, etc. As to a saving, by improving the engine load-factor a gas-engine would not, he considers, help at all. Such an engine has exactly the same drawbacks as a steam-engine in this respect; and more information is needed as to losses in a gas-generator over several weeks, corresponding with the losses in the steam-boilers mentioned.

The author has lately made some experiments with Mr. C. C. Carpenter on a compound horizontal condensing steam-engine at the Vauxhall works of the South Metropolitan Gas Company, using saturated steam. Six trials were made—three with, and three without, steam in the jackets. The results of these experiments gave from 12 to 16 per cent. gain due to the jackets in use. With 60lb. pressure in the boiler, and with all the jackets in use, 19⅓lb. of steam per indicated horse-power hour were consumed. The Cornish boiler used gave an evaporation of 8lb. to 10lb. of dry broken coke from a temperature of feed-water of 212deg. F. Dry coke per indicated horse-power hour, 2·5lb.; coke per brake horse-power hour, 2·7lb. Taking the price of coke at 1s. 1d. per cwt., this will give 0·3d. per brake horse-power per hour. The indicated horse-power varied from 43 to 63 in different tests, but the load was kept fairly constant during each eight hours' run. The thermal efficiency of the engine, with 60lb. steam and all jackets on, was 12½ per cent. The boiler efficiency varied from 63 to 79 per cent., according to the method of stoking. The boiler was not forced. The calorimetric value of 1lb. of gas coke varied from 12lb. to 13lb. from 210deg. F. per cent.; ash and clinker in coke, 9 to 14 per cent. The priming of the boiler was under 0·5 per cent., or practically nil. Mr. Holgate gives the following figures as to the first cost of steam and gas motors for an electric plant of 1,160 i.h.p. for 10,000 incandescent lamps: area available, 880 square yards; steam—five 160-h.p. boilers, six steam-engines, six dynamos, ropes, etc., £18,365; gas—Dowson generator plant, 11 gas-engines, 11 dynamos, belts, etc., £16,500.

INSTITUTION OF ELECTRICAL ENGINEERS, May 24.

Mr. ALEX. SIEMENS, President, in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Member.—Nathaniel Shepard Keith, 6, Queen-street-place, London, E.C.

Associates.—Arthur Barrett, 18, Park-side, Cambridge; Walter Eccles, Medina, Putney, S.W.; Charles J. Garnett, Keighley Electrical Engineering Company, Keighley; Percy Huddleston, 21, Upton Park-road, Chiswick, W.; G. C. F. Székács, Avalon, Eastbourne.

Students.—Alfred Howard Gossage, Faraday House, Charing Cross-road, W.C.; Alfred Lovell Phillips, 16, Peak Hill-gardens, Sydenham, S.E.; Charles Stirling, King's College, Strand, London; Howard Stanley West, Faraday House, Charing Cross-road, W.C.; Leopold A. S. Wood, 74, Cheapside, E.C.

The discussion on Mr. Crompton's paper, on "The Cost of Electrical Energy," was resumed.

Mr. Segundo said the public did not care how many watts were used in their lamps, what concerned them being merely to get a good light. He thought that there was not much room for improvement in boilers, engines, and dynamos, but improvements could be effected in the methods of distributing electricity, and especially in lamps. If the incandescent lamp could be improved so as to give one candle-power for 2·5 watts it would bring the price of electricity towards that of gas.

Mr. Shoolbred referred to the question of water-tube boilers, and could not agree with Mr. Crompton's theory that Lancashire boilers gave worse results. The cooling down of the system of network in water-tube boilers caused losses. With regard to the question of accumulators, he produced diagrams of the working of the station of the Bradford Corporation, which showed that considerable economy resulted from their use. Mr. Geipel, speaking of the proportion of capital to the units sold, had said that Mr. Crompton's figure of 2s. was almost impossible. However, at Bradford, the proportion had been 2s. 6d., and he considered that 2s. might certainly be reached before long.

Mr. Henwood said no method for the complete combustion of coal had been found. Hand shovelling was uneconomical, and the mechanical stoker was more wasteful. Moreover, the heat imparted to the fire-bars was a great loss. It paid best to use fuel of the highest calorific value. An internally-fired boiler was to be preferred to any other. To use coal with oil-fuel was a mistake. He had been able by reliable tests with oil-firing to obtain three times the evaporation of coal. He gave a brief description of the Petersen water-tube boiler, from which excellent results were claimed.

Mr. Dykes read a letter from Mr. Tonge, the engineer of the Preston Company, who sent a table of the cost of generation and distribution per unit delivered to customers by the Preston Electric Light Station. The figures were: January-June, 1893, total cost 3·42d.; July-December, 1893, 3·82d.; January to March, 1894, 2·710d. The station was exceptional in Mr. Crompton's list, as it was the only low-tension station where double-acting engines were in use, and Mr. Crompton had discarded them as abnormal. However, it would be seen that all the items showed a downward tendency, except coal, which was erratic, and had been affected greatly by the coal strike, the price in the locality having doubled. Mr. Crompton had not allowed for this. The efficiency of the distribution had been given by Mr. Crompton as 80 per cent., but Mr. Tonge made it more. The efficiency of the dynamos was 83 per cent., and as the sets were of only 100 h.p., this compared favourably with other results. The coal consumption per unit sold was 29lb., small slack being burned in Lancashire boilers. The best result they had obtained was 17½lb. of coal.

Prof. Unwin stated that Mr. Crompton's paper showed how much mechanical energy had to do with the financial results of central stations. He differed from the author as to Welsh coal being more valuable than north country coal, the only advantage of the former being its smokelessness. Three tests had been carried out, which showed 10lbs. evaporation per lb. of coal; two of these tests were made with northern coal and one with Welsh, showing them to be equal. Mr. Crompton had made strong assertions about the Lancashire boiler, which he virtually described as only half a boiler, it not being a whole one till an economiser was added. He had, however, made tests with a Lancashire boiler without an economiser, and obtained 11·78lb. evaporation. The Babcock was a good boiler, but he was doubtful about its being forced beyond its rated power. He thought that if the actual heating surface were taken into consideration, the results would prove not very great. Long-stroke slow-speed engines had up to now given the most economical results. Mr. Crompton had laid down a formula for central stations, which ran: "Welsh coal, Babcock boilers, high speed, short stroke, direct coupling." This, however, was not the only good formula available; and the speaker thought such formulæ mischievous. Prof. Unwin concluded by considering the question of the superheating of steam.

Mr. Peach referred to the Economic boiler, an important feature of which was the combustion-chamber at the back. The table No. 3 given by the author was valuable to central-station engineers, but it was of less value for a comparison of boilers. One of the most important points in the selection of boilers was the cost of maintenance and repairs.

Prof. Kennedy, in reference to coal consumption, mentioned that at Eccleston-place station, it had been got down to 4¼lb. per unit generated during the first three months of the year. The author had perhaps put the matter a little too far out of the scale. They might make a more possible ideal, the details of which he entered into, and get 3·46lb. of coal per unit sold. Prof. Unwin had referred to the question of evaporation in the case of north country coal. He (the speaker) would modify the former's statement; it was more difficult to get the value out, although with proper care it could be got out. At Glasgow a kind of tar from the gasworks was used in connection with the marine type of boilers, and it answered well. Concerning Lancashire boilers, tests made at Easton and Anderson's yielded an evaporation of 11·71lb. per pound of carbon value, whilst 12·4lb. had been attained—that was a high result. He believed such boilers could be made as economically as any others if they received proper treatment. In dealing with rope *versus* direct driving, he mentioned that a series of tests were now being conducted in Belgium, and that when the results were published they would prove of great value. As to obscure losses, tests at the Millbank station showed that those losses reached as much as 7 per cent. of the steam during a 24 hours' experiment.

Mr. Halpin and **Mr. Rosenthal** having gone into details concerning boilers,

Mr. Crompton replied to the discussion, and the proceedings of the last meeting of the present session were brought to a close.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

E.C.C. v. THOMAS PARKER, LIMITED.

We have received a letter from the E.C. Company in common, we suppose, with most other technical papers. We propose to give the subject-matter of this letter a little more prominence than it perhaps deserves, but it allows us to air a grievance which no doubt we have previously referred to, and most probably shall have to refer to again. Of course the first, and perhaps the last, thought of readers will be that technical papers are somewhat put out because they do not obtain patronage—that is, they do not get advertisements. That may be so. It is but a human feeling, after all, yet against this idea we protest. We desire patronage and support as much as anybody, but we would see the best man alive at the other side of the universe before we would condescend either to speak or to remain silent at his desire. We have before said, and we say it again, that two at least of the electrical journals are controlled, body and soul, by men interested in companies, and that these journals dare not say booh to any of a number of particular geese. If the public think they get independent criticism from either of these sources, they are mightily mistaken. Thomas Parker, Limited, has just applied to the public for money. It is usual when such application is made to supply the technical journals with a prospectus of the company; such observance, as far as we are concerned, has been in this case honoured in the breach. The formation of electrical companies at the present day is no longer a purely financial matter—that is, a mere matter of floating one more set of speculative shares for Stock Exchange purposes. Companies now floated have a substratum, more or less, of actual intention to do work and earn dividends. Technical journals probably know better than any other quarter the prospects of a new departure, and investors would do well to insist that promoters give them the opportunity of speaking. It is impossible to speak if the materials for criticism are not forthcoming, and we do not think it would be wise to enter into details upon a mere advertisement, which may or may not be a complete statement of matters as they stand. Although we think Thomas Parker, Limited, would have been better advised to have taken the Press more into confidence, we have no hesitation in going further and speaking in stronger terms of those who have rushed to get letters into the papers, mainly, we suspect, to secure good and gratuitous advertisements. Just let us examine this question—never mind for the moment about gratuitous advertisement; the people whom we mention are heartily welcome to all they get. According to the *Times*, "Thomas Parker, Limited," says "The vendor has acquired and will assign to the company the Eickemeyer patents for winding." The whole paragraph reeks of "winding"; and upon this the managing director of the Otis Elevator Company rushes into print about something totally irrelevant: but the opportunity is good, and he gets his advertisement. We also think that the E.C. Company has gone out of its way to ask the unbiassed and uncontrolled technical Press to advertise its objections to the prospectus of Thomas Parker, Limited. We have

Digitized by Google

not to provide any evidence of "good faith." We have published no prospectus which may contain libellous matter or incorrect statements; then why should we be asked to gratuitously advertise the contradictions? Some companies must think the technical Press a medium to command. They would be like the centurion—say, Do this and Do that, and expect it done without demur or question. When they, through directors or solicitors, control the paper, no doubt it is done, but not otherwise. If the E.C. Company object to anything stated in the Thomas Parker, Limited, prospectus, their remedy is simple, though it may be costly. It is cheaper, however, to get every paper to insert these contradictory or misleading statements, and so to make the public feel a little undecided as to the advisability of dealing with a new firm, than it is to prove the prospectus contains anything illegal, or even morally incorrect. Though two blacks never make a white, we might suggest that in connection with the formation of the E.C. Company itself there is a good deal of information we should even now like to obtain. Did the public ever know—does it know now—how heavily the company was handicapped through the grasping action of the promoters? Who were those promoters, and what was the amount of promotion-money they received? But to return to the E.C. Company's letter—it is very indefinite, except one point—namely, that the prospectus conceals a fact—the real position of the "Eickemeyer" patents. Now, unless we are misinformed, this definite statement is absolutely disputed, and in a telegram to the *Pall Mall Gazette* we have a distinct statement that "Thomas Parker, Limited, are the entire owners for the United Kingdom of the Eickemeyer patents for winding dynamos." The question of the position of the Eickemeyer patents is not exactly new, and it is admittedly under dispute, but that question is a question for the lawyers to decide, and certainly not one which we or the general body politic can decide. What does this move of the E.C. Company mean? Are they desirous of protecting the public? If so, their action comes too late. Are they desirous of counteracting the competition of a strong trade rival in the cheapest manner? If so, they will not succeed. Other paragraphs of this letter are altogether indefinite. One points to a "misleading statement," another to a "reason to believe that we shall have to," though the next states definitely that the matter has been placed "in the hands of our solicitors." That information is no doubt interesting, but not to us. We are not particularly anxious to know that the lawyers are to have another fight, or that there will be another long legal bill to pay. We have our own opinion on these matters, and though by no means addicted to that pleasant and profitable game so well known and followed in America, we do understand that even here bluffing is not always unremunerative. There is, however, always a consolation to those who bark, even if they cannot bite, that a statement made twenty-four hours in advance of the contradiction can never be fully overtaken. Hence it often pays to challenge and then run away.

REFUSE DESTRUCTORS.

The publication of Mr. C. Jones's (Ealing) book on this subject will no doubt direct the attention of local authorities and consulting engineers once more to the question of the utilisation of the waste heat obtained from this source. We have always held that there is refuse and refuse; that in certain districts, under ordinary circumstances, a vast amount of waste heat may be economically utilised; but in other places there will not be, except at irregular intervals, any waste heat to utilise. So far as the electrical engineer is concerned, he can point out how, when, and where the waste heat required can be obtained, and in approximately correct quantities. His examination, however, of the problem is usually from a different standpoint to that of the sanitary engineer. The latter will probably consider sanitary matters only. He has certain refuse to get rid of, and gets rid of it. If there is any waste heat he utilises it, but he does not start upon his design with the intention of getting waste heat. His intention is to destroy noxious matter. Thus in many cases all the heat generated will be required for the immediate object in view. Probably Prof. Forbes, in his investigation of the subject, took one of the very best districts possible to show what might be accomplished with dust-bin refuse, and we have no hesitation in saying there are numbers of districts wherein the required artificial light for the houses might be provided by the destruction of the dust-bin refuse by fire. On the other hand, there are other districts where this would be impossible. Mr. Jones has incorporated in the book we refer to a chapter by Mr. Tomlinson upon this question of power production. There is nothing new in what Mr. Tomlinson says. He only summarises various reports and papers, most of which have been given in this paper when read or published. One important point no doubt will in the near future be thrashed out by municipal engineers who are answerable for the sanitation of our towns. Is it possible to destroy dust-bin refuse such as examined by Prof. Forbes in one way, and refuse of other kinds in other ways? By so differentiating the refuse, they might do much to provide the artificial light publicly required, relieving the municipal bills in that way, though it is possible the getting rid of the other refuse might give an adverse balance to the accounts; in other words, it may prove more economical for authorities to use the best refuse to get rid of the worst, rather than to use the best refuse to obtain light and getting rid of the worst in another way.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

GAS UNDERTAKINGS IN RELATION TO THE USE OF GAS-ENGINES.

SIR,—After a lapse of nearly a year Mr. Lees has reverted to a paper of mine read before the Gas Institute at Belfast, and has endeavoured to show that I understated the number of gas-engines used in gasworks.

What I said was: "I believe there are about 1,600 gas-

Digitized by Google

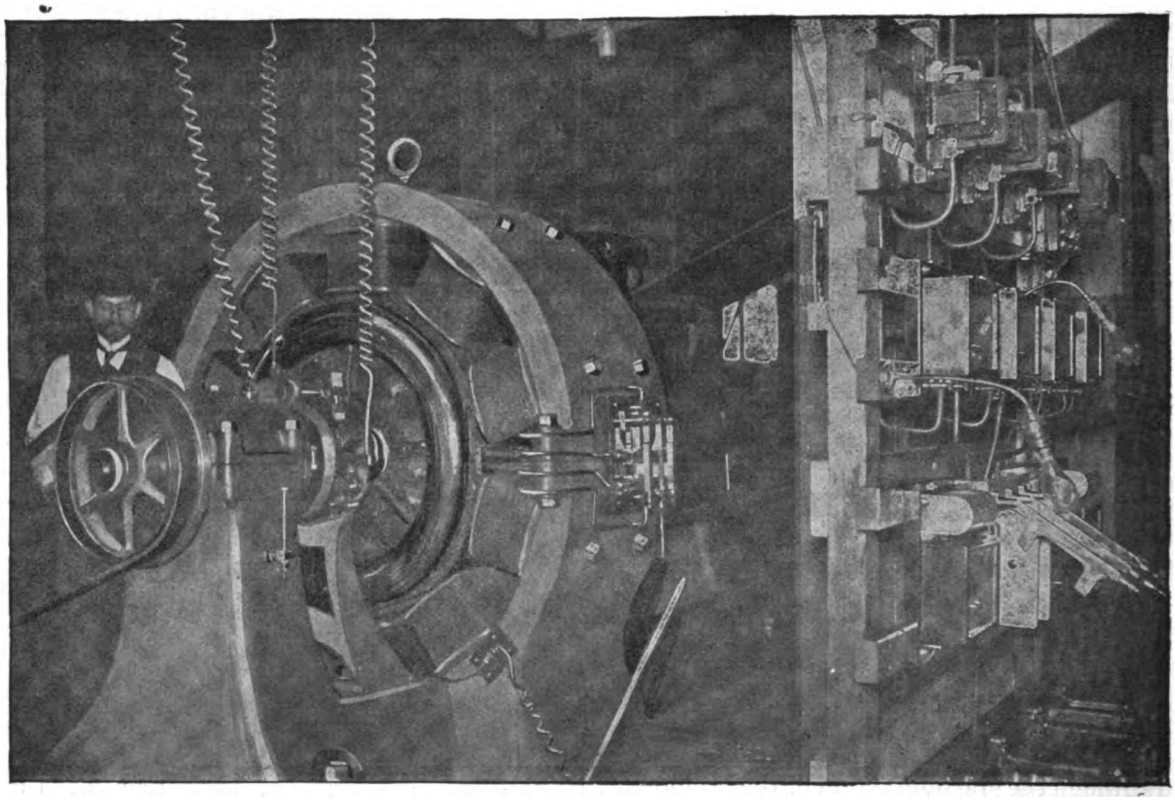

FIG. 3.—Synchronous Motor and its Switchboard.

works in the United Kingdom, but gas-engines are used at only 200 of them. In most cases these engines are of 4 h.p. nominal and under—several being of ½ h.p. and some less. There are only seven of 12 h.p., but five of 16 h.p., and none of larger size."

I may be wrong as to the number of gas-works in the United Kingdom, but as to the 200 engines in use a year ago, I beg to say that before writing my paper I wrote to all the leading makers of gas-engines, and they were good enough to give me particulars of all engines sold for gasworks. The figure 200 is based on this information, and if Mr. Lees will enquire more closely than he appears to have done, I think he will find that his opinion, not mine, "has been formed on insufficient evidence."—Yours, etc.,

May 21, 1894. J. EMERSON DOWSON.

THE THREE-PHASE TRANSMISSION PLANT AT TAFTVILLE, CONN.

In our last issue we gave a description of this plant, which has been put down by the General Electric Company of the United States. By the courtesy of the company, we are now enabled to give the annexed illustrations showing the application of the system. Fig. 1 is a plan of the power plant in the basement of the mill; Fig. 2 shows the main switchboard; and Fig. 3 the synchronous motor and its switchboard.

Electric Locomotives in France.—The Paris-Lyons-Mediterranean Railway Company are having three types of locomotives built, of which 40 compound steam locomotives of one type will be constructed. A second type is electric locomotives, in which the electric motor is installed on the rolling-stock, and the third type, it is reported, comprises 60 electric locomotives, each able to haul 800 tons at 15 miles an hour.

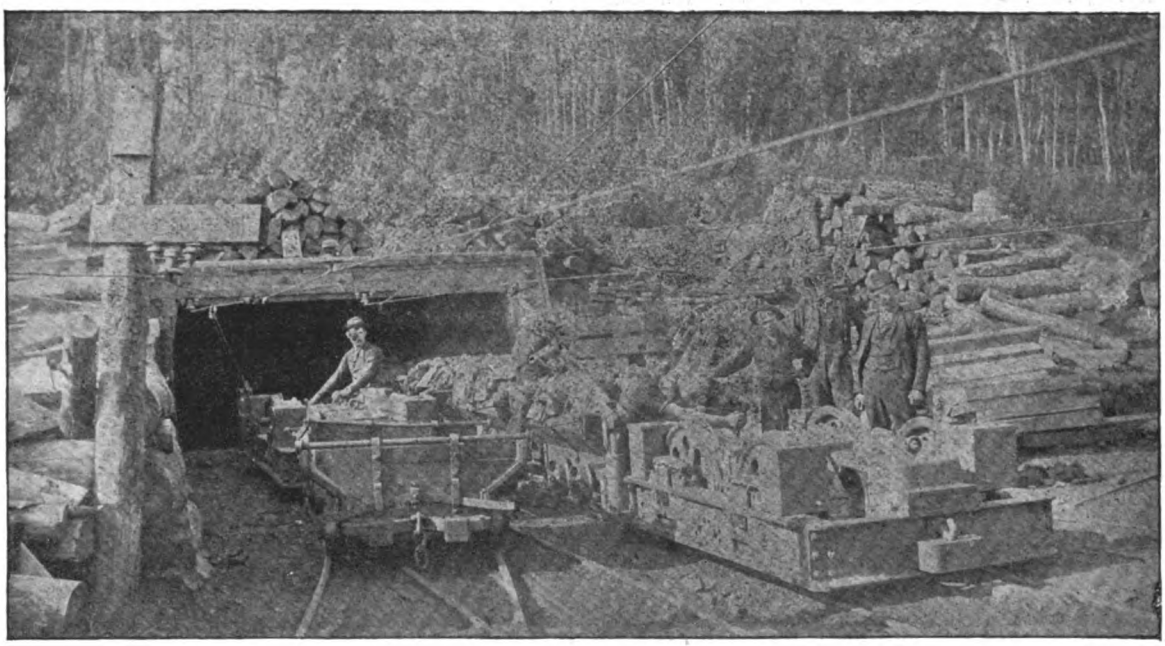
ELECTRIC HAULAGE IN MINES.

Concrete examples of the adoption of electricity to the exclusion of all older methods are generally more convincing in their import to the public mind than mere hearsay or description. The accompanying illustration shows a striking example of the supercession of older haulage methods by the electric mine locomotive in an important coal mine in Pennsylvania. The mine in question is the Rear Run Mine of the Blossburg Coal Company, near Landrus, Tioga County. The locomotives, of which there are two, are of the T.M.M. type—that is, "two-motor mining" type—each of 30 h.p., manufactured by the General Electric Company, of the United States. They are propelled by two W.P. 30 motors, one being geared to each axle. Current is brought to the motors by a specially designed trolley arm, on which the trolley wheel is swivelled to permit of its adjustment to the various irregularities of the wire line. The trolley arm can be set in sockets on either side of the locomotive, which may thus be run into headings on either side of the main haulage way, which is lighted by incandescent lamps placed at the entrance to each cross-head 100 yards apart. The dimensions of the machines are: horse-power, 30; speed, six miles per hour; draw-bar pull, 1,500lb.; gauge, 36in.; wheel base, 30in.; diameter of wheels, 28in.; width over all, 48in.; length over all, 9ft. 6in.; height above rail, 31in.; weight, 7,500lb. The current is furnished by a General Electric D. 62, 75-h.p. generator, driven by a Harrisburg Ideal 80-h.p. engine. The maximum load which these locomotives have been called upon to handle is 32 loaded mine wagons, each weighing 3,200lb., and the way is one part a 3 per cent. grade. The daily haul of the locomotives is about 650 tons. The entire plant has been pronounced eminently satisfactory, the locomotives having shown capabilities beyond the specification or the General Company's guarantee. Their presence in the mine has done away with the slow-going limited mule, and induced great economy. The small height of the machines above the rail level allows them to run into places impossible to any mule, and their ease of control and operation is such as to render them invaluable.



A NEW CONDUIT SYSTEM OF ELECTRIC TRACTION.

Our New York contemporaries describe the Johnson-Lundell conduit electric railway system, of which an experimental line has been laid down at East Sixty-nine-street and First-avenue, New York City. The track runs around a whole city block, with stiffish grades and difficult curves of necessarily short radius. The power-house is at the foot of the hill and at the centre of that section of the track or circuit. The generating plant comprises a vertical engine driving directly a pair of Lundell dynamos, the unit being such that it could be enlarged on exactly the same proportions up to any size for any road. The New York *Electrical Review* states that, by means of the interior conduit telescopic iron tube, current is carried to the track at the proper points of feeding, and is distributed without any loss due to leakage or conduction, owing to the high insulation of the ducts. The track itself is of ordinary construction as to the rails. Between the rails it is asphalted or paved. Examples of both are shown, and paralleling the rails lies a conducting bar or strip of metal embedded in the asphalte. This bar is level with the surface, and is divided up into sections, with insulating blocks of stone or other material between them. Just outside the single track, or midway between the double tracks, are plain boxes with iron covers flush with the street surface. In these boxes are substantial electro-magnetic devices which deliver current to each section as the car comes along, and then lie quiet until the succeeding car rolls up. These switch-boxes are water-tight, and may be compared to automatic switchmen. Each box governs its particular sections of track. The car carries a pick-up rubbing brush, which leads the current into the motor, and which takes the place, or fulfils the function, of the trolley pole wheel. There is one great difference, however, which the eye does not reveal. The trolley system is alive throughout. This is not alive anywhere except at the point over which the car is passing. The difference of potential between the two sides of the circuit between which the car moves is practically and actually nil.

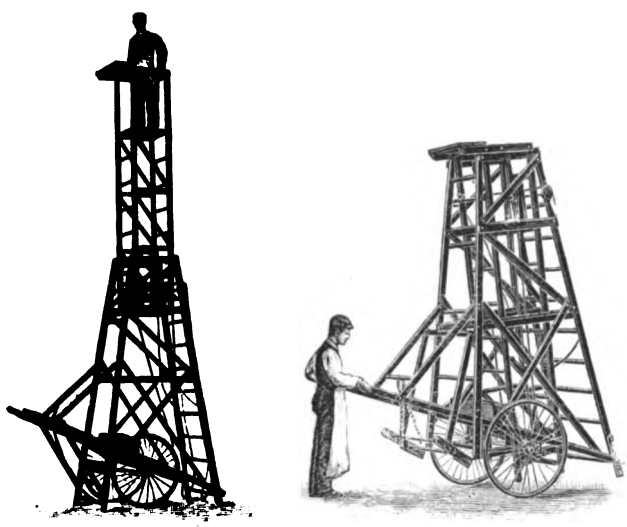
The car has but one motor, which is central under the car, and drives on each axle by means of bevel gear, and with sprocket wheels and link chain in flexible connection. Its suspension is flexible, the bevels are boxed, the sprocket wheels and links mesh noiselessly; and thanks to the intervention of a bipartite screw coil in close relation to the armature shaft, the motor, though capable of instantaneous arrest or sudden starting, never moves off or stops with a jerk. The motor is iron-cased and protected against dirt, stones, moisture, etc. Underneath the car is a steel brush which gathers up the current and passes it up into the motor, the return being, as usual, through the rails; the conducting strip between them is only alive when a car is right over it. Under the seats are frames holding a very simple, elementary form of lead storage battery, enough to furnish the voltage at which the motor runs—300 volts—and, though with very few plates in each cell, giving considerable capacity. The batteries are always in place; they need no change, practically no attention, but

Digitized by Google

at a moment's notice they furnish current and carry the car through many emergencies. The batteries play one or two parts in the internal economy of the car, "picking up the circuit" for a second when it starts; lighting the car; but their great beauty is that they render the car at once self-contained and dispense with the usual costly complicated and troublesome wiring at crossings, switches, steam-railway tracks, etc. If the car has not sufficient headway to run over a crossing, the battery will do that, just as it will keep the car going should it be deprived of central-station current, or even put on a line that is without electricity. The advantages claimed for the Johnson-Lundell system are absolute and immediate control of the car, moderate first cost, low rate of depreciation, independence of weather conditions, moderate cost of operation, independence of each car, freedom from noise, and ease of adaptation and extension.

STREET LADDERS FOR ARC LAMPS.

The annexed illustrations show a telescopic ladder tower, which has just been supplied to the National Electric Supply Company, at Preston, for a man to wheel about the roadways to attend to street arc lamps. The wheels are of the heavy cycle pattern, with spring wired rubber tyres, 40in. diameter. The base is 6ft. by 3ft. 6in. when closed, 10ft. 6in. high, and a platform in the sliding section, 2ft. by 1ft. 9in., enables the trimmer to reach



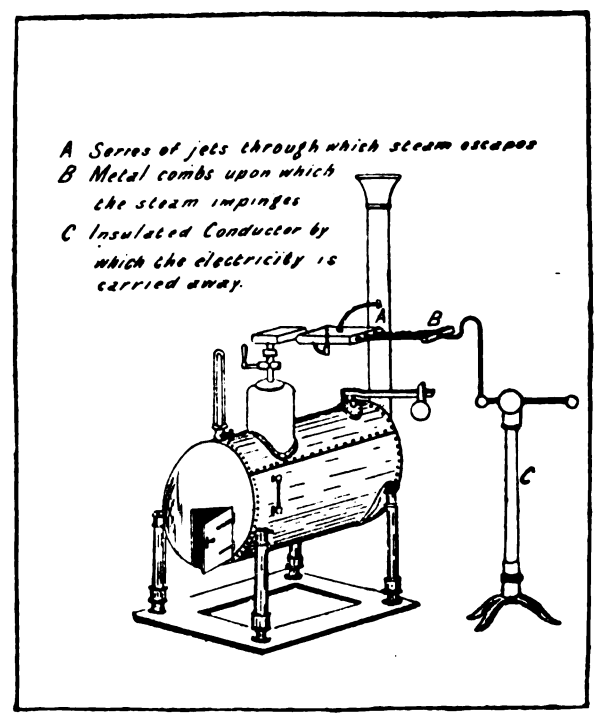
25ft., at the same time being surrounded by a guard rail which carries a small table. The construction is of Swedish fir, rungs of Quebec birch, with locks of steel to fall under any of the rungs, and actuated by an iron rod. Pulleys are fixed over which a rope runs in such a way that the upper section is raised or lowered with the greatest ease. Mr. Heathman, of 2 and 37, Endell-street, London, who supplied this telescopic ladder tower, is always busy designing new arrangements to suit the requirements of electrical engineers.

ELECTRICITY AND SOME OF ITS USES.*

BY SIR FREDERICK BRAMWELL, F.R.S., M.I.C.E.

I am honoured by the permission to deliver a lecture on the above subject before you this evening. At the outset I desire to make an apology (which I have no doubt I shall be tempted to reiterate during the course of my address)—namely, that I think it is all but a piece of impertinence to endeavour to compress any useful account of electric science as a whole, or to make any attempt to describe a tithe of the multifarious uses to which electricity is now applied within the short space of time that can be allotted to a single lecture. I purport to be about to lecture to you on electricity, and the very first statement that I have to make is a damaging one. I do not know what "electricity" is. But, on the other hand, I do not know what "heat" is. In a celebrated work "heat" is called "a mode of motion." I think I must be equally safe as regards "electricity," and say it is "a form of energy."

Although I do not know what electricity is, I know many ways of producing it, I know many ways of using it, and also know that it is a thing that can be bought and sold—a circumstance which, I trust, will be of growing interest to the inhabitants of Derby and to its Corporation. The following are some of the "many ways of producing it": I rub a stick of sealing-wax with a piece of dry fur. To show you it is electrified, I bring it near to this pith ball, with the result that the ball is moved. Similarly, I rub a rod of glass with a piece of dry silk, and I present that to the ball, and the ball moves. I have here another instrument which moves when affected by a current of electricity. I dip a plate of two dissimilar metals—zinc and copper—into some weak acid, and you will see the instrument indicates the presence of an electric current. I have here a series of plates of two dissimilar metals united at one end, and I heat these metals at their junction, and again you see the indication. In Canada, in the winter time, when the air is dry, it is a common thing for a man to rub his feet on the hearthrug, and thus to be enabled to light the gas with an electric spark from his knuckles. When I had more hair on my head than I have now, and the wind was north-east, the atmosphere being correspondingly dry, I have heard the crackling produced by combing my hair, and on turning out the light I have seen most unmistakable lambent flame as a result of the combing. I am sorry I cannot show you the hydro-electric machine constructed by Lord Armstrong many years ago, but I have put a drawing on the wall, Diagram 1. I need hardly say I do not put forward these diagrams I show to-night as works suited for your Art Gallery. You will see this apparatus of Lord Armstrong's consists of a steam-boiler carried on supports insulated from the earth. The steam escapes by the pipe, "A," and the friction produces powerful electrical effect. I have here a little implement, no doubt well known to you, which, on being operated, generates electricity adequate to light a gas jet.



A Series of jets through which steam escapes
B Metal combs upon which the steam impinges
C Insulated Conductor by which the electricity is carried away.
A
B
C

DIAGRAM 1.

I will now come to the much more important way of producing electricity in practice by the dynamo. The elements of action of a dynamo are—relative motion between convolutions of copper wire (or their equivalents) and a magnetic field. With respect to the magnetic field. I have here a permanent magnet, and, you will see, in the usual way these iron filings arrange themselves when spread on a piece of paper, that there is, as it were, "a virtue"—as it would have been called in olden times—or "a field," as we now call it, prevailing about the pole of the magnet. If I move backwards and forwards within this field some convolutions of copper wire, you will see that electricity is being produced.

I think I have now sufficiently justified my statement that this unknown thing, electricity, can be produced in many ways. With regard to its "uses in many ways." The first one with which I will deal is, for practical purposes, of the very highest importance—namely, its ability to produce magnetism. I have here an electro-magnet made of soft iron wound round about with insulated coils of copper wire, through which, at the present moment no current is circulating, and, as you will see, when I offer to it a handful of nails, there is no trace of magnetic action. But on passing an electric current through the coils, the nails are greedily seized and held by the soft iron, which has now become a magnet. I showed you that a permanent magnet, when a coil of wire was moved about within its influence, generated electricity. A very obvious mode of moving such a coil or coils is to place them upon an axle and to turn the axle. This principle of construction is carried out in the small dynamo, which I now show you, and, on the coil being set into rotation within the field of the permanent magnet electricity will be developed, as you will see by the fact of its lighting up this small incandescent lamp. Thus muscular energy has been turned into electrical energy, and has produced heat and light.

* Lecture delivered at the Guildhall, Derby, on May 16, 1894.

Digitized by Google

Now, that which is true of the effect of moving coils in the field of a permanent magnet is equally true, it need hardly be said, of moving them within the field of an electromagnet; and as such magnets can be made of any power required, the modern dynamo is, for industrial purposes, I may say always, constructed with electromagnets. It is an interesting fact in the history of electric lighting that the "Holmes" dynamo, having permanent magnets, which was tried at Blackwall in 1857 and then exhibited in the Exhibition of 1862, was, when I last visited the South Foreland Lighthouse—some three or four years ago—still at work, generating electricity for that light. You will have seen that to have an electromagnet we must first of all have a current of electricity, and the enquiry therefore is a pertinent one—Whence comes, in the first instance, the current to make the electromagnet? One of the early modes adopted for obtaining this was to use a permanent magnet in connection with a small dynamo, and to employ the electricity generated thereby in exciting the electromagnets of a larger machine. But after a time (and not a very long one either) it was found that the electricity produced by any continuous-current dynamo might be caused in whole or in part to traverse the coils of its own electromagnet, and thereby to establish its own magnetic field. But you may again say, "How do you get the first start?"

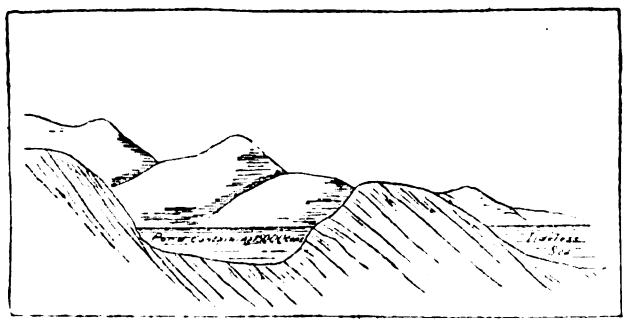


DIAGRAM 2.

In the very outset, by the effect, feeble though it be, of the magnetism of the earth. Afterwards, by the same source and by the residual magnetism—*i.e.*, the magnetism remaining in the metal of which the magnets are composed. I have shown you that when a convolution of wire is moved within a magnetic field the character of the electricity varies according as the movement is towards, or away from, the pole of the magnet, and also varies with the nature of the pole, whether a north or a south. You will say, therefore, at once that any dynamo constructed as I have suggested must produce a current which alternates—that is to say, is alternately in opposite directions. This is so, and the whole incandescent lighting done by the Corporation of Derby is—as I shall explain to you hereafter—done by means of an alternating current, and the magnets of the dynamos for producing this current are excited by electricity produced by small continuous-current dynamos. Your arc lighting, however, is done by continuous-current dynamos, and these, as I have already suggested to you, excite their magnets by the electricity they themselves have produced. I ought, perhaps, to tell you that a continuous current is obtained by "sorting," as it were, the alternating effects of the primary movement of a dynamo, so that all the impulses are directed one way.

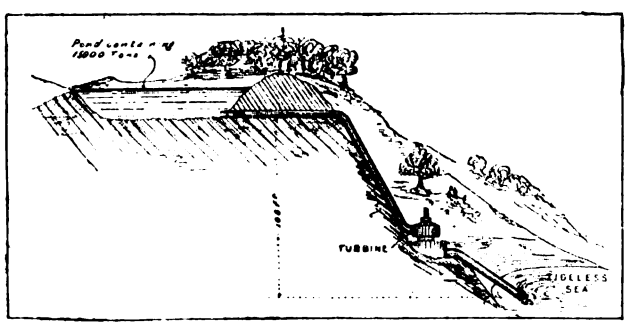

DIAGRAM 3.

We have now, very hastily and very imperfectly, reached the stage of my lecture where I trust I have shown to you how electricity can be produced sufficient for industrial purposes, and I must ask your indulgence for a little while I direct your attention to certain matters which must not be forgotten when considering the production and use of electricity. I find many persons, in common with myself, confess to more easily comprehend certain electrical facts by an analogy from behaviour of water, and I therefore propose to employ this to illustrate many points. Imagine a pond in a marsh, at the level of a tideless sea, say, a pond containing 15,000 tons of water as illustrated on Diagram 2. You will see that there can be no possibility of this water doing any work, in the way of driving a waterwheel. Suppose one were to cut a channel between the pond and the sea and to put a wheel in it. The pond and the sea being of one level, no flow of water would result, and the wheel would not turn. But look at the Diagram 3, where we have assumed the pond to be on the summit of a cliff 100ft. above the sea. If the water, under these circumstances, had an outlet from the pond, say, by a pipe sufficiently large to allow of 15 of tons water per minute flowing through it, and we were to put a turbine in that pipe, power would be obtained. In fact, the wheel would deliver, if there were no losses, that which is known as 100 h.p., and for nearly 1,000 minutes, or till the pond was empty. You will see I have contrasted the state of things where there is a body or weight of water having no fall, with a similar body or weight of water where there is a fall of 100ft. Let us make another contrast—10,000ft. fall or more, if you like, but with only an ounce weight of water to fall down. Obviously, this would be useless for power purposes. That which is really needed for purposes of obtaining power is quantity or weight of water multiplied by height for it to fall through. These facts, as regards water, are equally true as regards electricity, but we measure this, not in tons, nor in gallons of 10lb. each, but in "amperes." This is not a mere question of difference of name, as for practical purposes we cannot put electricity into a measure of capacity. You may, perhaps, have the notion, as you have heard of "storage batteries" (about which, if time admits, I hope to say a word or two), that electricity can be stored, as gas is stored in a gasholder. I wish it could be. It would be a delightful thing if one could have a small electric plant constantly working, and storing real, ready-made electricity to be used as we wanted it. You may ask me if an "ampere" is really a measurement. Although not a direct measure of quantity, it is an inferential measure of quantity, and again, to enable us to comprehend the difference the analogy of water comes to our aid. Take the case of an old-fashioned country millwright, who is asked as to whether a particular stream will drive a mill similar to one situated on another stream, the falls being equal. Such a man does not bother himself about gallons or cubic feet of water, but he takes a board to the existing mill, and puts it into the stream in the tail race from the mill, having previously cut a notch, say 4ft. long, in the board, and he sees how high the water working the mill is when passing the notch, taking care that all the water flowing down shall go through the notch. He takes the board back to the intended site, does the same there, and then finds that the water rises in the notch to the same, or to a greater height, and says at once there is the same, or may be more, water. But if it does not rise to the same height he may have, in fact, to reduce the notch

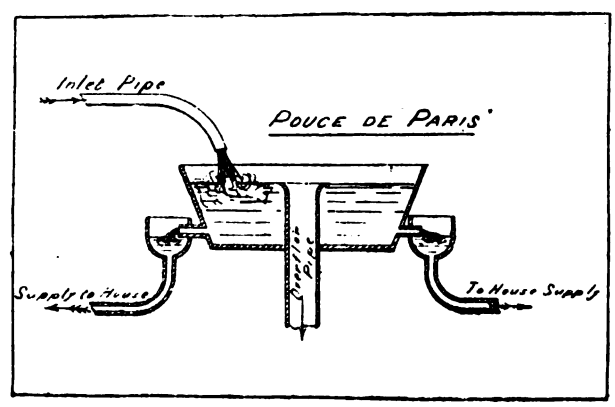

DIAGRAM 4.

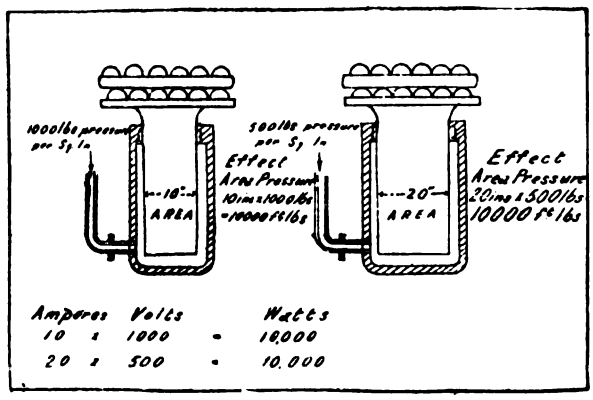
from 4ft. long to 2ft. long, before the water will rise to the old height. Under these circumstances, he says at once, there is only half the water here that there is at the other place, and this, although he is ignorant of how much water there is in either stream. Water for domestic purposes has been sold in a somewhat similar way. Diagram 4 shows, very roughly, how this was done in Paris. The water was pumped into a cistern in a tower. By means of an overflow pipe that water was kept at constant level. Round about the edges of the cistern, at a uniform distance below the surface of the water, holes of 1in. diameter, or the diameter of the thumb, were made, and the customer, according to the size of his house, took as much water as flowed through one thumbhole, or two, three, or four holes, and he paid so much for the water supplied by each hole, "Pouce de Paris." It was obviously perfectly fair. If the total income needed were 1,000 livres per annum, and if there were 1,000 holes, and for each hole one livre was paid, then the man with the small house being satisfied with the produce of one hole paid one livre, and the man with the large house, needing the delivery from 10 holes, paid 10 times as much—that is to say, each paid in proportion to what he got. Neither knew how much it was in actual quantity, but they knew it by "rate of flow." An "ampere" is a "rate of flow" of electricity.

Next, with regard to pressure of electricity. This is measured not in "feet head" or "fall," as water is, but in "volts." Once more, reverting to water. In Diagram 5 I have shown two hydraulic lifts or rams. Assume one of these has an area of 10in., and that there is a head of water or pressure of 1,000lb. on the inch. Such a ram would support a load of 10 by 1,000 equal to 10,000lb., and for every foot it rose there would be 10,000 foot-pounds of energy. The other ram I have shown to have an area of 20in., but with a water pressure of only 500lb. per square inch, but 20 by 500 again gives the 10,000, and again for every foot this ram rose there would be 10,000 foot-pounds of energy. Similarly, in electricity. If I have 10 amperes of quantity by 1,000 "volts" pressure, I obtain 10,000 "volt-amperes," called "watts." Again, if I double the amperes, and use 20, but at only 500 volts or one-half the pressure, 20 by 500 equals the 10,000 volt-amperes, or "watts." That is to say, in these two cases the electric energies

Digitized by Google

will be equal. Now, depending upon a number of details, into which time will not permit me to enter, a dynamo can be constructed and worked to produce electricity either at a high or at a low voltage. Assume two dynamos to absorb, say, each, the power of a 10 horse engine. They will turn out equal amounts of electrical energy, but they may do it, as I have suggested, either by a large output of amperes with a low voltage—such, for example, as is used in practice, in electric deposition, or in electric welding—or they may turn out a relatively small quantity of amperes, but at a proportionately high voltage, such as I will show you is useful in the arc lighting of your town.

As our time is limited, I think I had better at once proceed to talk about electric lighting in the two ways in which it is practically carried out—by incandescent lamps and by arc lamps With respect to incandescent lamps: I will begin with the very



1000lbs pressure per Sq In
Effect Area Pressure 10 ins x 1000 lbs = 10000 ft lbs
10"
AREA
500 lbs pressure per Sq In
Effect Area Pressure 20 ins x 500 lbs = 10000 ft lbs
20"
AREA
Amperes Volts Watts
10 x 1000 = 10,000
20 x 500 = 10,000

DIAGRAM 5.

old experiment, showing the result of the passage of an electric current through a piece of iron wire, which I can gradually shorten. I will start by transmitting the current through the whole length of the wire You will not observe any glow, but you will see it is hot, for it lights a match. The heat is due to the dissipation of electrical energy, owing to the resistance of the wire to the passage of the current and the reconversion of that energy into heat. I will now cause the current to flow through only half the length of the wire, and you will find the wire will begin to glow. You may say, "Why is this, as you have got only half the resistance you had before?" The answer is, that the resistance being halved, double the number of amperes are now flowing through, and that the loss of energy is intensified per unit of length, for it is double what it was before, and it is exercised in half the length It is, therefore, four times as great. I will continue to shorten the length of wire through which the current passes, and you will see that the brilliancy increases and increases until the wire fuses and breaks. I have used, as I told you, a piece of iron wire. Had I used a piece of copper or silver wire of the same size I should not so readily have obtained similar results, because copper and silver are much better conductors of electricity than is iron. To show

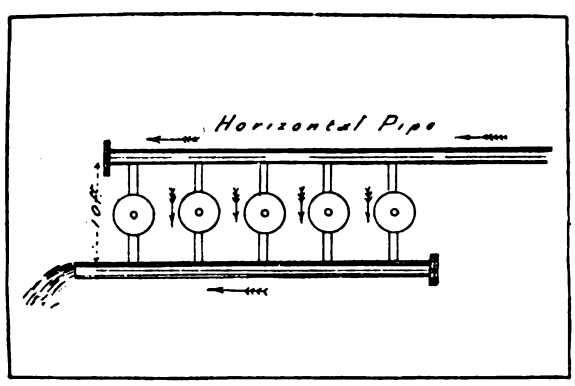


DIAGRAM 6.

the difference in the power of conduction of different metals, I have here a rough chain made of alternate links of silver wire and of platinum wire of equal diameters. I pass a current through this. You will see that every alternate link (the platinum) gives light, while every alternate link (the silver) remains dark, proving that the silver is the better conductor. You may be tempted to say, "Why this is the glow or incandescent lamp that is wanted. All that is necessary is to employ a fine platinum wire." Much time, and thought, and money were spent in this direction, but they were all wasted. When platinum is heated sufficiently to give a proper glow, it speedily perishes. It would occupy the whole evening to go through the mere history of incandescent lamps. We must leave it on one side, and I must content myself by saying briefly that, as you all know, incandescent lamps are made in these days by the employment of a charcoal—*i.e.*, carbon—filament. There is one unhappy difference between platinum and charcoal. The latter cannot be used in contact with the air, even for as long a time as the platinum. I have here a lamp to which I have admitted the air. I pass a current through the filament, and, as you see, it is destroyed almost immediately. But if this same filament be enclosed in a glass bulb from which all the air has been exhausted, the filament can only glow; it cannot burn to destruction, for there is not any air to support combustion, and the light is obtained. An incandescent lamp is so very familiar an object, and it appears so very simple now that we know all about it, that one is hardly disposed to accord to it the admiration it deserves, for it is the outcome of years of deep thought and hard work, and even now the processes employed in its manufacture are by no means simple. But although, speaking generally, it has ceased to interest us, to my mind it is a marvellous thing that a mere thread of charcoal, $\frac{1}{100}$in, in diameter, or less, should be brought to so hard a condition as to be as elastic as a steel spring, and that this slender thread should be heated to a point competent to give light in quantity sufficient to illuminate large rooms without being itself destroyed. This is all time will allow me to say about electric incandescent lamps.

I will now consider the modes adopted for distribution of electricity through a town to a number of houses, and the use of the electricity there, whether "in parallel" or "in series," and to make my meaning clear, I must use again a water illustration. In Diagram 6 I have drawn a horizontal pipe, conveying a large quantity of water, enough to work a certain number, say five mills, the pipe supplying to each of them 15 tons of water a minute.

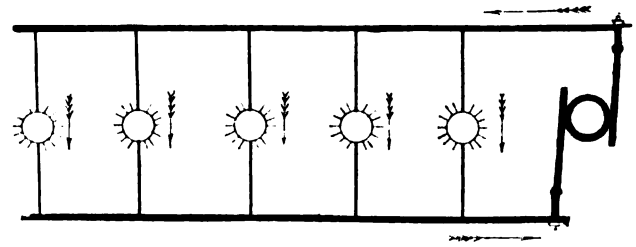

DIAGRAM 7.

Ten feet below the first pipe, and parallel with it, I have drawn a second pipe, and between these two I have placed the five mills, the only connection between the pipes being through the mills. If all the mills were stopped, the water would not flow from the one pipe to the other. If one mill were put to work it would take its 15 tons per minute; if all five were put to work, they would take their 75 tons per minute. This may be called the "parallel"

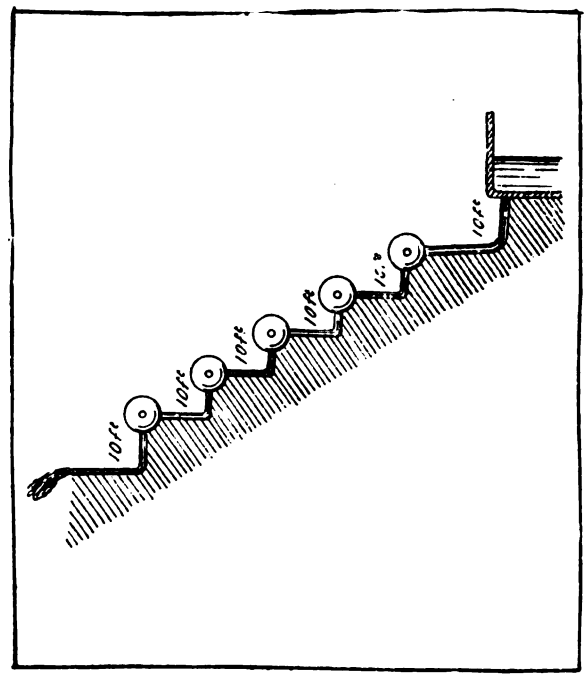

DIAGRAM 8.

system of water distribution. In Diagram 7 I have shown the electrical comparison—a dynamo, with a wire coming out from it. Parallel with that, another wire going back to the dynamo. The only connection between these two wires being through five incandescent lamps Suppose each lamp to take a third of an ampere. If one is at work, only one-third of an ampere is flowing from one wire to the other. If all five are at work, then one and two-thirds are flowing. I have given you these small numbers of lamps; but, of course, in practice they are multiplied by hundreds or thousands. If the difference in voltage between the two wires be, say, 100 volts, it is obvious that each lamp is using one-third ampere by 100 volts, and this is an arrangement very commonly employed.

I will now go to another system of distribution. Diagram 8 shows the water-pipe, no longer horizontal, but descending a steep hill-side. The pipe is much smaller, as although each of the five mills drawn requires the same power as any one of the five mills on the "parallel" system, only sufficient water need be brought to work the first mill, or one-fifth of the quantity in the former case. For, being on the steep hill-side, we can put the

Digitized by Google

second mill 10ft. below the first, and the water which has worked the first mill will pass through the second and work it, and so on, to the fifth. But you will see that, although we have used only a fifth part of the water we did in the "parallel" system, that fifth part has fallen through, not the 10ft. fall of the "parallel" system, but a 50ft. fall, and therefore the water energy expended has been the same (as you will realise it must be), to do the same work. Similarly, in electric lighting, the lamps may be "in series," as shown on Diagram 9. I have before me a row of incandescent lamps which are "in series." The same quantity of electricity flows through all the lamps, but I am compelled to have four times the pressure or voltage for these lamps in series that is needed for each single lamp. I have hitherto dealt with incandescent lamps only, but you are well aware that there is another kind in your streets—the arc lamp. In the case of these lamps there is not any filament carrying

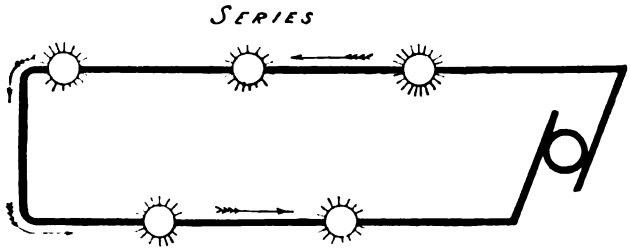

DIAGRAM 9.

a current through it; but there are two sticks of carbon, in holders, capable of moving towards one another, and these sticks are by most ingenious arrangements maintained with their ends at the proper distance apart, to cause the electricity to experience the requisite resistance in leaping across the space between the ends, thus making that which is called the "arc" from carbon to carbon. Each of these lamps requires about 10 amperes, and each lamp involves the lowering of the electrical pressure by about 45 volts. Now, as in the case of the "series" water mills, if I were to start with 10 amperes, at 45 volts it would light one arc lamp; but if I start with the 10 amperes, at 90 volts, then after the electricity has passed through the first lamp there would still be 45 volts left, which would be competent, therefore, to light a second lamp. But if I started at 450 volts I could similarly light 10 lamps; or, if I had 1,800 volts, I might light 40 "in series." The construction of these arc lamps is so extremely ingenious, having regard to the automatic arrangements by which the ends of the carbons are kept at the right distance apart, notwithstanding they are constantly burning away, and by which, if any failure occurs, so that a lamp ceases to burn, the electricity shall still go through the lamps before it and after it, and thus prevent the whole of the 40 lamps "in series" from being extinguished by reason of the failure of any one of them, that I very much regret time will not admit of my giving you some description of these most ingenious arrangements, but I show you here one of the lamps such as are employed in your street-lighting. By this time you are aware that the ratios of the quantity and of the pressure of electrical energy may be varied; and also that the size of the mains must depend upon the quantity of current they have to carry, and not upon the pressure at which that current is passing. It is desirable, therefore, to increase the pressure within reasonable limits in order to keep the mains small.

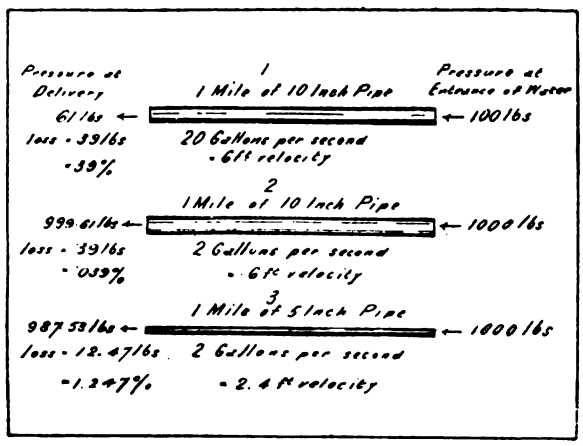

DIAGRAM 10.

I will once more revert to a water analogy. If I desire to convey power, hydraulically, by means of water having a pressure of 100lb. on the square inch where it enters the main, as shown in Diagram 10, and to convey it one mile, and that I have a 10in. pipe, and the quantity I need is 20 gallons a second, equal to 6ft. velocity; then, without troubling you with the calculation, you may take it from me that the loss of pressure due to the overcoming of the friction through the pipe will be 39lb. out of the 100lb. per square inch, leaving an effective pressure at the delivery end of the mile of pipe, therefore, of only 61lb., the loss being, as you will see, 39 per cent. But take the next case shown on the diagram, where the water pressure at the entering end of the pipe has been increased to 1,000lb., equal to 10 times as much pressure. I can, with such a pressure, perform the same work by a tenth part of the water, or only two gallons per second, equal to 6ft. velocity. The actual loss in pressure under these circumstances will only be 39 of a pound, so that you see the losses in pressure diminish as the square of the quantity, but the percentage loss differs in a much higher ratio—namely, inversely, as the cubes of the pressures, for it becomes reduced to 039, or about $\frac{1}{25}$th of 1 per cent. For practical purposes, however, one does not retain the same size of main, either for water or for electricity, when high pressures are used, but advantage is taken of the altered state of things to diminish the size of the mains. On the same diagram I have shown what would happen if a 5in. main were employed, instead of a 10in. main. The two gallons per second would now demand a velocity of 2·4ft., and the 1,000lb. pressure would be reduced to 987½, giving a loss of 12½lb. out of the 1,000lb., or 1·25 per cent. Similarly, with electricity. There is a loss in pressure by conveying it along the conductor, depending upon the quantity (amperes) put through. The actual loss of energy can be decreased by reducing the amperes and correspondingly increasing the voltage, and the percentage of loss, as in the case of water, will be still more decreased. Having regard to the frequent desirability of being able to place the generating station at some distance from the parts of a town where the electricity will most commonly be used, or it may be to the large area to be lit from one station, and to the great cost of the large mains needed to transmit sufficient energy at a low pressure, it is obviously advantageous to have means by which the pressure may be increased and the quantity passing be reduced while still delivering the same amount of electrical energy For purposes of "transport," if I may use the term, it may therefore be very desirable to have a pressure of, say, 2,000 or 3,000 volts at the generating station and in the mains or some of them; but one would hardly care to have that pressure in a dwelling-house, and, moreover, for the purposes of incandescent lighting, one could not, in the present state of the art, employ such a pressure satisfactorily in a lamp.

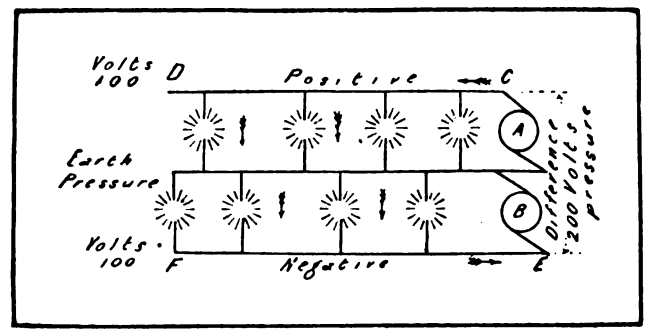

DIAGRAM 11.

Up to the present time the pressure which is commonly employed in an incandescent lamp is 100 volts, but lamps of 200 volts are in use, and I think it not at all improbable that before long incandescent lamps of 200 volts, or of even higher pressures, may come into very general regular use. But for the purpose of illustrating one mode by which the pressure of transmission may be reduced to the pressure employed in the lamp, I will ask you to look at Diagram 11, illustrative of the "three-wire system." I think I cannot do better in describing this arrangement than use the very words of Dr. John Hopkinson, the inventor of this system, as given in his patent specification, where he says: In order to combine the advantages of comparatively high potential in the feeding conductors with lower potential in the houses in which the electricity is used, I make use of a system of three conductors in combination with two dynamo machines coupled in series . . . "A" "B" represent the two dynamos, "C-D" and "E-F" represent the extreme conductors, which I call the positive and negative conductors, and "G-H" represents the intermediate conductor. The positive pole of the dynamo machine, "A," is connected to the conductor "C-D," and its negative pole to the conductor "G-H." On the other hand, the positive pole of the dynamo machine, "B," is connected to the conductor, "G-H," and its negative pole to the conductor, "E-F." The houses to be supplied are divided into two approximately equal parts, preferably the houses being taken alternately. The houses of one part are supplied between the conductor, "C-D," and the conductor, "G-H"; and those of the other part between the conductor, "G-H," and the conductor, "E-F." The intermediate conductor, "G-H," may be of much smaller dimensions than either of the other two, as it has only to carry the difference of current consumed by the two divisions of consumers—that is, those connected with the conductor "C-D," and those connected with the conductor "E-F." It need not be insulated, and, indeed, it may be replaced by the iron, or other metallic covering, often used to protect the copper conductors. In cases where the two divisions of consumers may be safely assumed to have a very approximately equal consumption at all times, the intermediate conductor, "G-H," may be replaced in part by the earth, and the negative pole of the dynamo machine, "A," and the positive pole of the dynamo machine, "B," be connected together and to the earth. You will realise that it is obvious this principle may be carried to more than three wires, and on this point Dr. Hopkinson says: "This system may be extended by using more than two dynamos in series, and

Digitized by Google

dividing the consumers into as many groups, there will then be two large conductors connected to the extreme poles of the dynamos and a number of smaller intermediate conductors, one less than the number of machines, each connected to the junction of two machines of the series."

I think you will agree with me that the three-wire system is a very ingenious method of enabling the mains to be reduced in size when the current has to be delivered to consumers spread over a large area; but there is another mode—namely, that of the use of induction coils, now called transformers, by means of which much larger changes in voltage, between that of generation and that of distribution, can readily be made. I will ask you to look at Diagram 12. You will see there a comparatively fine wire, making 20 turns round about a bar, on which there is also a single turn of a comparatively coarse wire. The fine wire has delivered to it a comparatively small quantity of electricity, but at a high voltage—say, 2,000—the result of the arrangement being that, although there is no connection between these two wires, but mere contiguity, the single coil of wire will have generated in it electricity, with the pressure reduced to one-twentieth part, or down to 100 volts, while the quantity will be increased 20 times. These are the ratios in use in the transformers in this town. That is to say, the current at the station is generated at a pressure of 2,000 volts, or even higher, and is reduced by transformers in the street boxes to the safe pressure of 100 volts, at which it is distributed, and enters the houses of consumers. I should have said that this action only takes place with such an implement as this when there is a change in the condition of the electricity passing through the fine wire, such as very rapid intermissions in a current all in one direction, or such as—and this is commonly the practice for commercial purposes—the changes attending the employment of an alternating current.

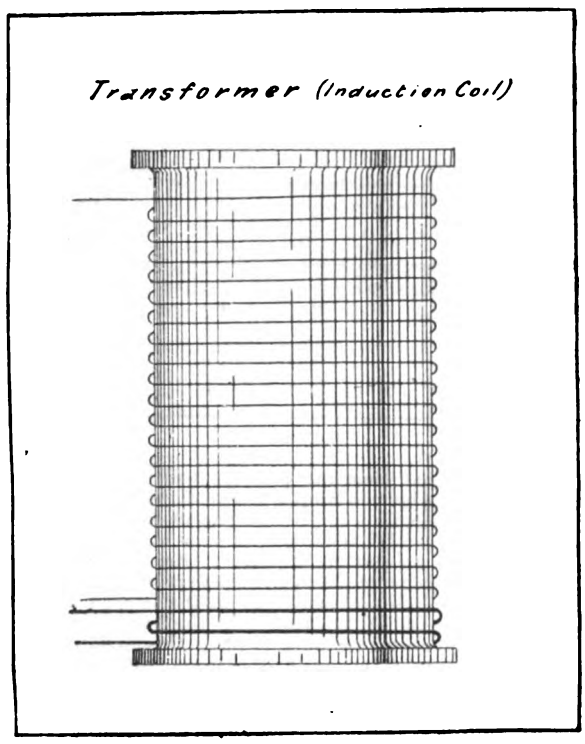

DIAGRAM 12.

Continuous current of high voltage can be reduced to continuous current of low voltage by causing the current of high voltage to drive a motor which drives a dynamo so wound or arranged as to produce low-voltage electricity. If you will remember, in the very early part of the evening, I pointed out that the currents produced by the dynamo were alternating, and that they were made continuous by a "sorting" arrangement. If this "sorting" be not done, then an alternating current is obtained, and it is, as I have said, that such a current is sent through your streets, and is made use of in the transformer. I have here before me two implements that have been in use for very many years under the title of Ruhmkorff coils, but which are really transformers. The one on the right hand is receiving a rapidly interrupted current from a primary battery having a low voltage. It is increasing this voltage enormously and is correspondingly diminishing the quantity, so that I am enabled to transmit the electricity by the extremely fine wire which you can hardly see, that extends from one of these coils to the other. On applying this current to an electric lamp, you will see that no glow is produced. But the second transformer is being worked in the reverse way to the first—that is, the electricity is being changed back again into low voltage and considerable quantity, and a lamp put into the circuit at this part will light up efficiently.

I promised that if time admitted I would say a few words about storage batteries or accumulators, as they are generally, though erroneously, called. The pair of plates of dissimilar metals immersed in a suitable liquid, such as I used early in the evening, and the battery I have just employed with the Ruhmkorff coils, are called primary batteries, and they will continue to work for a certain time until the active element becomes exhausted, when this element must be renewed before more electricity will be produced by them. The so-called storage battery, when in use, consists in the employment, as in the primary battery, of practically two metals, but actually of only one metal—lead—but in two different states or conditions; this is immersed in an appropriate liquid. It differs from a primary battery, however, in that when it is becoming exhausted, by reason of the plates of metal tending to come into similar conditions, instead of remaining in dissimilar conditions, the sending of a current of electricity the reverse way through the battery will restore the plates to their dissimilar condition, and thus render the battery once more capable of going to work and producing electricity. You may have noticed I used the term "so-called storage batteries," and I have done so because they do not "store" electricity, but they have within them the potentiality of going to work and of producing electricity. If anyone were to send you 9,000lb. of water heated up to the boiling point, you might properly say that he had given you a "storage of heat," as much as would require, say, 100lb. of coal to raise it from the temperature of the air to the boiling-point in an ordinary boiler. But if instead of the 9,000lb. of hot water he had sent you 100lb. of coal, it would hardly be correct to say that he had sent you so much heat. It would be true that he had sent you "the means" of producing so much heat—the "potentiality." So, therefore, a so-called storage battery has within it not the electricity, but the potentiality of producing it.

I am afraid I must ask you to be content with this most imperfect sketch of electricity generally, and of its application to lighting purposes. Time will not permit of my giving you more detail. I told you that I do not know what electricity is, but that I did know many ways of producing it, and also many ways of using it. At present, I have only dealt with one of those ways—namely, lighting. But the other ways are numerous now, and no doubt will be much more numerous a few years hence. A very early employment of electricity, as you all know, was in electro-plating—that is, the deposition of a metal out of its solution. Nowadays this process is carried to such an extent as to be used not only for mere plating, but for forming the whole substance of an article. Copper tubes, for instance, are made entirely by the deposition, electrically, of copper from its solution. The old use, telegraphy, I need not more than mention. The more modern use, telephony, at this time excites no attention whatever, although if 20 years ago it had been asserted that speech uttered in London could by the aid of electricity be not conveyed, but reproduced in Paris, or, as it is daily, in Derby, it would have been looked upon as an absolutely idle, or may be false, suggestion. Welding is a use of electricity. By the aid of appropriate machinery to give pressure, pieces of metal heated by the passage through their extremities of an electric current can be welded with absolute cleanliness and certainty. And many metals of which the welding point is so near to that of absolute fusion that they cannot be welded by ordinary means, can, by the aid of electricity, be thus united. Aluminium is a striking example of such a metal.

With regard to transmission of power, you are all aware that you can construct an implement, exactly like a steam-engine, with its cylinder, and piston, and slide valves, which, if you turn it round by some power, will pump water, and that this very same machine, if supplied with water under pressure, becomes an hydraulic motor—implements such as these being largely used for working capstans on the quays and docks, and in railway goods yards. Similarly, if you turn a dynamo round by power, it will produce electricity; but if you supply it with electricity, it will act as a motor. I have such an implement here, and you will see it go to work, driving a blowing fan. By means of such motors, tramcars and the City and South London Railway and the overhead railway at Liverpool, are being worked. You have, within the last few days, opened here in Derby an exhibition, where may be seen specimens of electromotors, of the machinery, plant, and implements used in electric lighting for domestic and public purposes, ornamental internal fittings and lamps, and apparatus employed in the useful and comforting operations of heating and cooking, of kettle-boiling, of heating electric irons for laundries, and it would not surprise me to hear of electric curling irons for ladies' hair. At you all doubtless know, electricity is also used in many industrial undertakings—in bleaching, for the treatment of sewage, and for innumerable other purposes.

Such are the uses of to-day. It is impossible to say how far these may be extended, even in the course of the next 10 years, but that such extension will come is absolutely certain. I must now bring this lecture to a conclusion, begging of you to remember that nothing but the barest outline sketch can be given of so vast a subject in a single lecture.

THE PACIFIC CABLE QUESTION.

Sir Charles Tupper has sent the following reply to Sir John Pender in reference to the letter printed in our last issue:

Victoria-chambers, 17, Victoria-street, London, S.W.,
May 17, 1894.

Dear Sir John Pender,—In reply to your letter of the 15th inst., received yesterday, after I had read it in the *Times*, I must first express my regret that you were prevented by indisposition from being present when my paper (of which I had sent you a copy)

Digitized by Google

was read at a meeting of the Royal Colonial Institute on the 8th of May.

You say: "I cannot allow your statement to pass unchallenged that 'the protest against the proposed cable is largely based upon fallacies.'"

Those who read that protest will find that it is largely based upon two statements, which I regard as fallacious. First, that "the existing service was established solely by private enterprise—no Government subsidy, guarantee, or exclusive landing rights having been granted to the company."

I do not think any person reading that statement would suppose that the "existing" companies with which the proposed Pacific cable will compete are now, and for many years past have been, assisted by Government subsidies and guarantees, amounting to the present time to £2,100,000. The Eastern Extension Company alone have received of that amount about £643,000, and the African lines, described by you as an alternative route to Australia, £1,337,000.

Second, that the calculations made in the protest to show the unprofitable character of the undertaking assumed that the life of the cable would be only 14 years.

You say: "You are entirely mistaken in stating that some 5,350 miles (or about 30 per cent.) of the 18,000 of cable now forming the system of the Eastern Extension Telegraph Company is more than 20 years old and is still in working condition."

My authority for that statement was the Berne list, published in 1892, as furnished by the Eastern Extension Telegraph Company to the International Telegraph Bureau, and which I accepted as reliable. The following are the figures:

	Date of laying.	Length of cables in nautical miles.
From Madras to Penang	1870	1,455
From Penang to Singapore	1870	415
From Singapore to Saigon (Cochin China)	1871	637
From Saigon to Hong-Kong	1871	983
From Singapore to Batavia (Java)	1870	539
From Banjowangie to Port Darwin	1871	1,137
From Flinders, near Melbourne, to Low Head (Tasmania)	1869	180
Total		5,346

I will now add the highest existing authority on that question. Sir John Pender, at the meeting of the Brazilian Telegraph Company on the second of this month, said: "As you are aware, one of these cables is 20 years old, and therefore it is at all events approaching a period of age which causes us to be careful in providing for its renewal."

You say: "Then again your description of the existing system as a 'monopoly' cannot be justified."

I do not know what you call a monopoly, but I have under my hand the report made to the Government of Canada by Mr. Sandford Fleming (who was one of the Canadian delegates to the Colonial Conference, held in London in 1887). In that report, speaking of the discussion upon this cable question, he says:

"The Postmaster General (Mr. Raikes) stated very forcibly that it would be absolutely impossible for the English people or for her Majesty's Government to recognise the monopoly which the company seemed to claim."

With the evidence before me that the active efforts are now in operation to promote the construction of a Pacific cable under the control of a foreign Government, I cannot share your doubt as to its probability, nor can I agree with you as to the strategic value of a British Pacific cable, concurring as I do with the opinion expressed by the *Globe* of the 19th ult., which, in an article very friendly to the existing lines, says:

"In the first place, there can be no question at all that a cable across the Pacific would be of the very highest strategical importance to us. Not only would it furnish us with a duplicate medium of communication with our furthest colonial possessions, but it would also have the advantage of standing less chance of being cut by our enemy in time of war. The eastward bound cables, by means of which we communicate with Australia at present, touch far too many places *en route* to be strategically safe. Moreover, if an enemy should succeed in cutting the cable, it would probably be somewhere between Aden and England, in which case India would be completely cut off from telegraphic communication. The proposed Pacific cable, however, would then enable us to transmit our messages by an alternative western route."

I do not propose to discuss the question of traffic or the normal increase that may reasonably be expected further than to say that I have reason to believe that no difficulty will be experienced in securing the construction and operation of the cable upon the lines suggested by the Wellington conference, or such a modification as may be adopted by the conference shortly to be held at Ottawa.

Having confined my remarks to the principal points raised in your letter, I remain yours faithfully,

CHARLES TUPPER.

P.S.—I have sent a copy of this letter to the *Times*.
Sir John Pender, M.P.

Portsmouth.—It is reported that an armature was burnt out last week at the central station. Preparations for the starting of the installation are being actively continued, and 68 of the arc lamps were lit a few days ago. The Electric Lighting Committee have fixed June 6 as the date of installation.

REPORT OF THE ROYAL COMMISSION FOR THE CHICAGO EXHIBITION.

We give the following extracts from the report issued a few days ago by the Royal Commission for the Chicago Exhibition:

"The size of the Machinery Hall, including the annexe, was 1,396ft. long by 422ft. broad. In this building 33,000 square feet were allotted to Great Britain. This space was fully taken up in London by 60 exhibitors; 20 of these, however, failed to exhibit, and a space of nearly 6,000 square feet was left vacant. Some of this space was reallotted to exhibitors who came in at a later date, and, as far as possible, a readjustment was made of the previous allotments. Many exhibitors, however, had completed their stands, or had put down foundations, and were not able to shift their position even when a more advantageous space was offered to them. Eventually, vacant spaces, amounting in the aggregate to 2,000 square feet were left. The British section in this department was placed under the charge of Mr. H. D. Wilkinson, who was also responsible for the mining and electricity departments. The Chicago executive undertook to supply power for driving machinery in motion, but the chief of the department, Mr. L. W. Robinson, expressed a strong desire that power for driving the machinery in the British section should be supplied by British engines, and he undertook that, if the engines were lent and their freight paid to Chicago, all the expenses connected with their installation and working would be defrayed by the administration. The Commission were fortunate in obtaining engines under these conditions from Messrs. Galloways and Messrs. Willans and Robinson. Messrs. Galloways lent a horizontal compound engine, indicating 350 h.p. Messrs. Willans and Robinson provided two of their patent central-valve engines of 360 i.h.p. and 165 i.h.p. The details of the performances of these engines are given in a report by Mr. H. D. Wilkinson, which forms an appendix. Messrs. Willans and Robinson also showed one of their 300-h.p. engines coupled to a Siemens Bros. dynamo. This plant was placed at the disposal of the electrical department, and supplied current for four large Schuckert search-lights, which were shown every night on the Manufactures Building, and for other purposes. The performance of the engines supplied by Messrs. Galloways and Messrs. Willans and Robinson left nothing to be desired, and as each engine was of a distinctive and novel type in America, they both attracted considerable attention.

"In the Electricity Department, the building for which was 690ft. by 345ft., Great Britain was very poorly represented. Special efforts were made by the Electrical Committee, who were anxious to show at Chicago a typical English lighting station, and they also endeavoured to illustrate domestic electric lighting by showing a number of fitted rooms, as has been done in some exhibitions in this country. They, however, were not successful in either attempt. It had also been hoped that a share in the electric lighting of the exhibition might be allotted to some British firm, but the negotiations under this head came to nothing. It was by the division of the whole lighting scheme into sections, for which contracts were entered into with different nationalities, that the lighting at Paris was such a representative display. With one or two exceptions, notably in the case of Messrs. Siemens and Halske, who had the contract for lighting the terminal station, the whole of the electrical plant was American. In the Electrical Building no steam was furnished or allowed, the idea being that electrical power alone was most appropriate. This secured a grand display for the electrical transmission of power, but was fatal to a large class of exhibits of great importance. Practice in both lighting and power is now almost entirely in direct-coupled engines and dynamos, and such plant of this character as was exhibited could either not be run at all, or had to be run by making the dynamo a motor to turn the engine. This affected three exhibits. The reluctance of English electrical firms to exhibit at Chicago was no doubt due, at all events in part, to the fact that most of them had taken part in the special electrical exhibitions which have recently been held at Frankfort and at the Crystal Palace. The most important contribution in this department was the collection of historical telegraphic apparatus, lent by her Majesty's Postal Telegraph Department, and exhibited at the expense of the Commission. The collection included apparatus dating from 1837, and also modern telegraph apparatus, as used at the present day in our telegraph department."

Mr. H. D. Wilkinson, engineer to the British section, reports as follows in the appendix referred to:

"For operating the various machinery in the British section, power was supplied by the shafting, by steam, by electric motors, and by compressed air. Three exhibitors of looms ran their machinery by electric motor, because by that means they could operate for as many hours as they wished daily, whereas the line shaft was only run from 8 a.m. to 5 p.m. Except in the case of electric motors, no charge was made for the supply of power when the machines using the same were not performing any work, but where anything was being driven by engines or manufactured by machines, a charge was made for the power estimated to be in use. It was impossible to measure the power absorbed by the various classes of machinery operated, but in every case I was able to negotiate a satisfactory understanding between the exhibitors and the chief of the building as to the amount of power actually used, and upon this the exhibitors agreed to pay. Steam was charged at the rate of 40dol. for six months' supply per horse-power, or at four cents per horse-power hour. Compressed air was supplied at 60dol. per horse-power for six months, or at five cents per horse-power hour, and power from shafting was charged at the rate of 50dol. per

Digitized by Google

horse-power for six months. Exhibitors who chose to drive by electric motors had to purchase their motors from the manufacturing companies, as they could not be obtained on hire. The company having fixed a motor, there was then the cost of connecting it to the mains, for which the exposition had a scale of charges ranging from 20dol. per horse-power for a motor of ½ h.p. or under. to 10dol. per horse-power for over 10 h.p. The current supplied was direct at 500 volts, and the scale of charges for the six months ranged from 80dol per horse-power for ¼ h.p. and less, to 60dol. per horse-power for over 2 h.p. Gas was also used for operating gas-engines and other exhibits, and was supplied from the works of the Hyde Park Gas Company, situated outside the exposition. The charge was made 1dol. 50 cents per 1,000 cubic feet, with a discount of 30 per cent. if paid within six days from date of bill; no charge was made for meters, but a deposit was required. A charge of 3dol. was made for a permit to open ground and make connection to main, besides which there was the cost of laying branch pipe to exhibitor's space, and the connections from branch pipe to exhibitor's machinery. In our section I arranged for one pipe to be laid, sufficient to meet all demands, and divided the cost of the same between the exhibitors requiring gas supply. Water was supplied from the exposition pumping station, and was charged for at the rate of 10 cents per 1,000 gallons. The water-meters put in by the department were charged to the exhibitors. The cost of fitting was as follows: permit for connecting to main, 3dol.; permit for connecting to waste, 3dol.; cost of meter, 15dol. to 25dol.; cost of branch pipe to exhibitor's space, and cost of plumbers' work to exhibitor's apparatus."

Another appendix deals with the engines in the British section. It is as follows: "The horizontal compound engine lent by Messrs. Galloways (Knott Mill Ironworks, Manchester) was suitable for indicating 350 h.p. at 70 revolutions per minute, with 100lb. boiler pressure. It had low-pressure cylinder, 30in. bore, placed over the high-pressure cylinder, 17in. bore, both having a stroke of 3ft. 9in. The piston-rods of these two cylinders drove on to one crank-pin by means of connecting-rods, the slide block for the low-pressure cylinder working on slide recessed in the bed-plate, and that for the high-pressure cylinder on steel slide bar forming a stay between the cylinder and the framing. The engine was fitted with Galloway's latest gear, the distribution of steam being effected by short slide valves. The high-pressure cylinder was provided with multi-ported or gridiron expansion valve working on the back of the main slide. The main slide was operated by eccentric from the crankshaft, and the expansion valve by curved slotted link, with an improved motion patented in 1890, allowing the admission of steam at full pressure, without the intervention of a throttle-valve, and giving a quick cut-off from any point from 0 to 66 per cent. of the stroke of the piston. The governor was driven by gearing, and was of the improved parabolic type, giving great sensibility and steadiness of turning; it was connected directly to the rod of the expansion slide-valve, which it controls, giving admission of steam according to the load upon the engine. The crank necks are 12in. in diameter, and the shaft carried a flywheel 23ft. in diameter, grooved for 12 1¼in. ropes. The condenser was placed in rear of the engine, the air-pump being horizontal, worked direct by continuation of the low-pressure piston-rod. The engines lent by Messrs. Willans and Robinson, Thames Ditton, Surrey, were Willans patent central-valve engines, of 360 i.h.p. and 165 i.h.p. respectively. They were single acting, all the brasses being kept constantly in compression, or 'in constant thrust' (instead of being alternately pulled and pushed, as in ordinary engines), with the object of enabling them to run with smoothness and silence at extremely high speeds; the normal speeds of the two engines shown being, for instance, 350 and 380 revolutions per minute respectively. To scientific engineers the engine is well known from the two series of trials carried out by its inventor, the late P. W. Willans, described in papers read by him before the Institute of Civil Engineers in London, in the discussion of which various American engineers took part. The economy figures given by those trials are still 'record figures,' the consumption falling as low as about 18½lb. per indicated horse-power per hour non-condensing, and to 12·6lb. and 12·8lb. condensing. The engines were in both cases triple-expansion, with high steam pressure (170lb.), but they were very small, indicating less than 40 h.p., and running at 400 revolutions per minute. The larger engine shown had three cranks, and of the standard 'III' pattern; the smaller one, with two cranks, was of 'HH' size. The single-acting 'constant thrust' engine is distinctively an English exhibit, as, although known in America, it was extensively used in England (in the form of an earlier type of the Willans engine) for several years before it was taken up there. English experience of it, in fact, extends over nearly 20 years. The one simple engine for combined dynamo and belt driving was of 60 i.h.p., at 470 revolutions per minute. Another engine, of 300 i.h.p., was also shown, coupled direct to a Siemens Bros. (English made) two-pole dynamo, capable of giving 180 kilowatts, or 200 if required. The machine was armed to give 1,000 amperes and about 112 volts, at 350 revolutions per minute. The combined efficiency of engine and dynamo was about 85 to 86 per cent.—that is to say, that for each 100 i.h.p., 85 e.h.p. or 86 e.h.p. is obtained at the terminals of the dynamo, and electrical losses in the latter amounting to 14 or 15 per cent. In plant such as that shown, with compound engines, the consumption of steam per electrical horse-power per hour is about 24lb. non-condensing, with triple-expansion condensing engines of the same pattern it falls to barely 15lb. Though exhibited by Messrs. Willans and Robinson, Limited, the makers of the engines, this plant was lent by Messrs. Siemens Bros., Limited, of Woolwich, England, to whom it belongs."

An appendix is also given by Mr. Wilkinson concerning the supply of electricity. He says: "It was by the division of the whole lighting scheme into sections, for which contracts were entered into with different nationalities, that the lighting at Paris in 1889 was such a representative display. With one or two exceptions, notably in the case of Messrs. Siemens and Halske, who had the contract for lighting the terminal station, the whole of the electrical power plant was American. Secondly, in the Electrical Building, no steam was furnished or allowed, the idea being that electrical power alone was appropriate to use. This secured a grand display for the electrical transmission of power, but was fatal to a large class of exhibits of great importance. Practice in both lighting and power is now almost entirely in direct-coupled engines and dynamos, and such coupled plant here exhibited could either not be run at all, or had to be run by making the dynamo a motor to turn the engine. This affected our section in three exhibits. The general lighting of the various buildings was by arc lamps run in series on direct-current circuits, but for all incandescent lamps and arc lamps required by exhibitors the supply was by high-tension alternating current with transformers. The high-tension wires at 2,500 volts were carried through subways to the principal points in the grounds, and from transformer pits located at points along the route current at 100 volts was taken into the various buildings. The contract for the supply of this current was in the hands of the Westinghouse Electric Company. The charge made by the Exposition Company for the use of lamps for six months was as follows: per incandescent lamp of 16 c.p., 8dol.; arc lamp of 2,000 c.p., 60dol. To obtain this service the exhibitor had to pay the above in advance, together with the cost of making connection, wiring, and fixing lamps—viz., per incandescent lamp, 3·50dol.; per arc lamp, 3·50dol. The New York Insulated Wire Company had the exclusive right of putting in all wiring for exhibitors, and instances occurred in our own foreign section in which exhibitors had put in their own wiring, but could not obtain current for their lamps until they had paid the above wiring charges to the exposition. There was great delay in the fixing of exhibitors' lamps, as the first attention had to be given by the electrical department to the general lighting of the grounds and buildings, this being very much in arrear. Up to the expiry of the first three months the full amount of 8dol. per lamp had to be paid in advance, and claims for rebate on the time of non-supply claimed formally afterwards, but requisitions for light after August were allowed on an advance payment of less than 8dol. per lamp, according to the time for which light was actually supplied."

A further appendix confirms the official report on the Electrical Congress concerning the formal adoption of legal units of electrical measure by different Governments. This report was given some months ago in this journal.

COMPANIES' MEETINGS.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.

The twenty-seventh ordinary general meeting was held last week at Winchester House, Mr. W. S. Andrews presiding.

The **Chairman**, in moving the adoption of the report, said the receipts for the half-year ending December 31, 1893, were £80,538. 18s. 3d., as compared with £86,954. 11s. 2d. in the corresponding period, showing a diminution of £6,600. Remembering the state of things that existed during the half-year in Brazil that was very satisfactory. The remarkable point was that notwithstanding the many interferences with their business which had taken place, there had been no loss of traffic. On the contrary, there had actually been an increase. The diminution in the receipts was consequent upon the unfavourable exchange prevailing in Brazil. The average exchange in the half-year had been 10¾d. against 1s. in the corresponding period, and that record of lowness was being surpassed at the present time, for the exchange now showed a still further reduction. Compared with the par of exchange, they thus lost £20,715, while the Platino Company, the net receipts of which undertaking came to this Company in the shape of dividend, lost during the year £16,563. These two amounts together came to £32,278, or 2½ per cent. on the capital of the Company, so that but for this exceptional state of exchange they could have paid 5 per cent. instead of the 2½ per cent. now recommended. They were adding £5,000 to reserve, and carrying forward a balance of £1,045.

Mr. C. W. Earle seconded the resolution, which was carried after some discussion.

AFRICAN TRANSCONTINENTAL TELEGRAPH COMPANY.

The adjourned ordinary meeting was held last week at 19, St. Swithin's-lane, the Duke of Abercorn presiding.

The **Chairman**, in moving the adoption of the report, stated that from a mail received he learned that the surveyors and contractors for the Salisbury-Tete section had completed their survey, and that the telegraph route was cut over 220 miles, practically the whole distance. The work of cutting this route was very difficult in consequence of the great scarcity of water, and the country was found to be very rocky about 70 miles from Tete. The contractors stated that they would be ready with their party to start the construction at once, if the material were at hand. The delay in its arrival at the western terminus of the Beira Railway, near Chimoio, was, they hoped,

Digitized by Google

now overcome, and the material in the course of transit to Salisbury. They relied upon the support of the Government to overcome the difficulties raised by the Portuguese as to the construction of a line within their sphere of influence, and they learned that negotiations were now on foot to promote this end.

The resolution was adopted.

BUSINESS NOTES.

Paddington.—The Paddington Guardians have decided to light the infirmary wards by electricity.

Western and Brazilian Telegraph Company.—The receipts for the week ended May 18 were £2,545.

Brechin.—The Town Council have not yet arrived at a decision as to whether or not to promote a provisional order.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 20th inst. amounted to £1,282.

Dunoon.—The Town Commissioners will shortly meet to consider the question of lighting the Castle gardens by electricity.

Ashton-under-Lyne.—The Town Council have nominated a subcommittee to consider the question of establishing a central station.

Hertford.—The Electric Lighting Committee are enquiring into the probable support of the inhabitants to an electric lighting scheme.

Birmingham.—The City Council will erect a meat market and slaughter-houses in Bradford-street. They are to be lighted by electricity.

West India and Panama Telegraph Company.—The receipts for the two weeks ended May 15 were £1,455 less than for the corresponding period of 1893.

Royal Institution.—The Friday evening discourse at the Royal Institution on June 1 will be delivered by Prof. Oliver Lodge, F.R.S., on "The Work of Hertz."

An Inspector Required.—As will be seen from our advertisement columns, the Commissioners of Sewers of the City of London are about to appoint an inspector under the Electric Lighting Acts. The salary will be £250 per annum.

Stock Exchange Quotation.—The Charing Cross and Strand Electricity Supply Corporation have applied to the Stock Exchange Committee for the vendors' shares Nos. 7 to 214 and 719 to 10,000 to be quoted in the official list.

Electric Motive Power Company, Limited.—This Company has been registered with a capital of £20,000 in £1 shares to enter into an agreement with E. J. Clubbe and A. W. Southey, and to carry on business as electrical and mechanical engineers.

South Staffordshire Tramways.—The petition for the winding up of the South Staffordshire Tramways Company was on Wednesday ordered to stand over till June 13, so that a meeting of shareholders may be called, at which the directors have agreed to tender their resignation.

Messrs. Drake and Gorham.—The lighting of the University Galleries extensions has been given to this firm, who recently carried out the installation at Balliol College, and also Balliol House, at Oxford. There will be about 14 Brockie-Pell arc lamps and about 70 incandescent lamps.

City and South London Railway.—The receipts of the Company for the week ended May 20 were £907, against £794 for the same period last year, or an increase of £113. The total receipts for the first half-year of 1894 show an increase of £477 compared with those for the corresponding period of 1893.

Chiswick.—The Local Board have received a letter from Messrs. Bourne and Grant concerning works for electric lighting in Chiswick, stating that they were anxious to proceed with the works, and were digging at the pumping station to obtain foundations. As soon as they got down to the exact depth they would send in plans to the Local Board.

Brighton.—Three tenders have been received by the Lighting Committee of the Town Council for supplying the alternating-current cable required for Preston and North-East Brighton, together with the necessary joints and boxes. The highest tender is £4,745. 3s., and the lowest £3,579. 6s. The latter is from the British Insulated Wire Company, and has been recommended for acceptance.

West Coast of America Telegraph Company.—The report of the directors for the year ended December 31 last states that the gross income for the year was £15,096, as against £22,218 in 1892, and, in order to make up the loss on the year's working and to meet the debenture coupons, it was necessary to take £16,536 from the reserve. The total expenses were £19,632, against £21,919 in 1892, a saving of £2,286.

Plymouth.—At a public meeting held the other day, Mr. Bond, in reply to a ratepayer who suggested that the water wasted in winter in the borough might be utilised for the purposes of electric lighting, said that the Corporation had been granted a monopoly of the public lighting, and that the water engineer had been directed to report how far the waste of water could be utilised to produce electricity.

Immisch Electric Launch Company, Limited.—This Company has been registered with a capital of €12,000 in £1 shares. The object is to acquire the undertaking of the Thames Launch Department from the General Electric Power and Traction Company, Limited, in accordance with an agreement made by this Company with the General Electric Power and Traction Company, Limited, and to carry on and extend the operations of the same.

Richard Hornsby and Sons, Limited.—The directors have declared an interim dividend on the preference stock at the rate of 6 per cent. per annum, for the half-year ending June 20 next. They propose no interim dividend on the ordinary shares, and in future will pay none, considering it wiser to refrain from distribution, until the stocktaking at the close of the financial year has revealed the true position of the Company.

Southampton.—The Works Committee of the Harbour Board reported last week on a letter received from Mr. Kerbey Bowen, confirming the arrangement as to the supply of electric power to launches, and the wharfinger was instructed to confer with the consulting engineer as to the further cranes required at the quay extensions, etc. Instructions were given for the electric lighting at the pier and pavilion, to be carried out by the Board's own labour.

Engine Fitters.—The Corporation of Cardiff are about to appoint four practical engine fitters for the purpose of taking charge of the engines and plant at the electricity works, Canton, Cardiff, and invite applications for those posts. Applicants must be resident within the borough of Cardiff, practical engine fitters, and not more than 45 years of age. The salary offered is £2. 2s. per week. Applications are to be sent to the town clerk by June 4.

Morecambe.—The Local Board recently interviewed the secretary (Mr. J. Jowett) and the engineer (Mr. T. Preece) of the Morecambe Electric Light and Power Company with reference to the alleged nuisance arising from the company's works. After some discussion, Mr. Preece expressed a desire to go into the matter thoroughly; and it was ultimately agreed that he and the medical officer and surveyor should meet and consult on some occasion when the nuisance was perceptible.

Llandudno.—The Electric Light Committee of the Town Commissioners have had under consideration the draft of the provisional order for the electric lighting of Llandudno submitted by Messrs. Bellis and Kingsland. The committee cannot recommend the Board to agree to the terms of the order, and they are of opinion that the question of electric lighting should stand adjourned for a time, having in view the fact that the constitution of the Board will undergo a change in November next. The Town Commissioners have adopted the minutes.

Brighton Hotel.—When the shareholders in the Brighton Grand Hotel Company met last week, the chairman (Mr. Van Tromp) stated that the report of an enquiry committee contained no attack whatever upon the directors, except, possibly, a want of judgment with regard to the electric lighting. If it was desirable to take the light from the Corporation, the directors would be the first to support the suggestion; but after the economies going on, showing a saving of £600 or £700 a year already in generating it on their own premises, it would be as well to continue the present installation.

Ruston, Proctor, and Co.—The report of the directors to March 31 states that the trading results for the year, including a balance brought forward of £4,613, show a balance of £48,940, from which has been deducted for depreciation of plant and machinery, office furniture, directors' remuneration £4,409, leaving £44,531; out of this there has been paid the interest on the debentures and interim dividend of 5s. per share (£18,750), leaving a net balance of £25,781. The directors propose to devote £10,000 in reduction of goodwill account and to pay a dividend of 10s. per share, making 7½ per cent. for the year, leaving a balance to be carried forward of £3,281. 4s. 8d.

Tenders for Bedford.—As notified in our advertisement columns, the Corporation of Bedford invite tenders for the construction, supply, and laying down of the necessary plant and mains for the supply of electricity in the borough. The contract will be divided up into two sections—(1) construction, supply, and erection of boilers, steam-engines, gas-engine, economiser, feed-pumps, condenser, alternators, and switchboards; (2) supply and laying down of transformers and mains. Specifications may be obtained from and plans may be inspected at the office of F. H. Medhurst, M.I.E.E., 13, Victoria-street, Westminster, S W. Tenders are to be delivered by June 16.

Hampstead.—The Vestry have approved of the forms prepared by the Electric Lighting Committee with regard to the supply of electricity by the Vestry to private consumers. There are two forms, the first giving information concerning the electric light and application for supply, and the second being an agreement for supply, with rules for supply and regulations for installation work. The Vestry hope shortly to be prepared to supply electricity in the compulsory area in the parish. A cheque for £120 has been drawn in favour of Mr. W. H. Preece on further account for commission on the amount certified in connection with the erection of the central electric supply station.

New Brighton.—An electric light supply has been installed at the Palace, New Brighton, Liverpool. The installation comprises a gas-engine, which drives a 300-light dynamo, and two pumps, which supply the building with spring water. The plant is fixed in the grotto and open to the public. The grotto is lighted by about 30 16 c.p. lamps, and the dancing hall is illuminated from upwards of 20 electroliers. The skating rink, aviary, and theatre are also electrically lighted. Outside the Palace there are arc lamps. One of the most attractive features of the open-air display is the signboard illumination, which is a construction of different coloured lamps, switched in and out automatically, and alternately showing in all about 20 different combinations of colour.

Digitized by Google

Salisbury.—The Town Council held a special meeting last week to consider a communication from Mr. W. H. Gramshaw relating to the proposed formation of a company to supply electric light within the city. The town clerk read the application, which asked the consent of the Council to a provisional order to be applied for to the Board of Trade before July 1. It appeared that the promoters of the company had obtained the freedom of acquiring from the Dean and Chapter the Old Town Mill for the purpose of providing motive power. After some discussion, during which a general opinion was expressed in favour of the scheme, the meeting was adjourned for a week in order to test public feeling on the matter, and to obtain from Mr. Gramshaw fuller information with regard to the proposed undertaking.

Douglas Bay Tramway Company.—An extraordinary general meeting of the shareholders of the Douglas Bay Tramway Company was held on Monday, to pass a resolution to voluntarily wind up the Company and to appoint a liquidator for that purpose. The Company has been bought up by the Douglas and Laxey Electric Tramway Company, who in completion of their purchase paid £18,000 on May 1 to the representatives of the shareholders of the old Company, the balance of the purchase-money being taken in shares in the new company. The proceedings on Monday were formal—the passing of a formal resolution being necessary in order that the £18,000 lying at the bank to the credit of the old company might be distributed amongst the shareholders. The statutory meeting requisite to confirm the meeting is fixed for June 13.

Accepted Tenders.—The following tenders were received by the Brighton Corporation for the supply of motor alternators, transformers, meters, etc.:

J. Fowler and Co., Limited, Leeds	£5,147	0	0
Manchester Edison-Swan Company, Manchester	3,940	0	0
Siemens Bros. and Co, Limited	2,560	0	0
Brush Electrical Engineering Company, Limited	2,450	0	0
Easton, Anderson, and Goolden, Limited	2,125	0	0
Crompton and Co., Limited	2,110	0	0
Electric Construction Company, Limited, Wolverhampton	1,731	17	0

The tender of the Electric Construction Company has been accepted.

Bournemouth.—At a meeting of the Lighting Committee of the Town Council a letter was read from the Bournemouth Electric Supply Company, Limited, giving notice of their intention to give a continuous supply of energy in certain streets, and another letter from the same company was read, enclosing statement of the company's accounts for the year ending December 31, 1893. A letter from the Board of Trade was read, enclosing copy of correspondence with the electric supply company and a report by Major Cardew, R.E. The letter and enclosures have been referred to the surveyor to report upon. The town clerk reported that the Board of Trade had issued the electric lighting license, and the surveyor has been instructed to report on the power at his disposal for electric lighting purposes, and generally on the subject, with estimates. He has been authorised to engage assistance at a cost not exceeding £10. 10s.

Belfast.—The Electric Lighting Committee of the Town Council met last week, when Mr. M'Cowen, the resident electrical engineer, submitted a report on the progress of the works since the last meeting. Plans and specifications for the central station, which had been received from Prof. Kennedy, were examined, and it was agreed to advertise for tenders for the carrying out of the work. Several applications for electric light were received from parties outside the area of supply, and the committee decided to grant these if the applicants complied with the electric lighting order, and entered into written contracts to continue to receive and pay for the supply of energy for at least two years, of such an amount that the payment to be made for it at the rate charged to consumers within the area should not be less than 20 per cent. of the outlay incurred by the Corporation in providing the electric lines for such purpose beyond 60ft. from the proposed distributing main.

Glasgow.—The Works Committee of the Clyde Trust have had under consideration for some time the question of the lighting and providing of crane accommodation for the new Cessnock Dock In December last a report was submitted to the committee, containing information collected on visits to English and continental ports regarding electrical and hydraulic appliances. In view of the recommendation in that report that tenders be taken for an electric light installation to light the dock and work nine cranes on the south quay of the north basin, the sub-committee were directed to take tenders for nine 35cwt. hydraulic cranes and installation for working the same, and alternatively tenders for nine 35cwt. electric cranes and installation. The committee accordingly procured 12 tenders for hydraulic power installation, and 20 for electric power installation, but none of the tenderers, though requested, furnished any data as to the cost of working and maintenance. An examination of the tenders showed that the first cost of the electric installation would be much greater than hydraulics, and this fact led the committee to recommend the adoption of a hydraulic installation for this part of the dock.

The Telephone System.—The report recently circulated that all the numbers of telephone subscribers were to be changed induced a *St. James's Gazette* representative to call at the offices of the National Telephone Company to enquire the cause of so radical an alteration. He was at once informed (says our contemporary) that the rumour had scarcely any foundation), the fact being that of all the thousands of subscribers only 500 would be affected. The change was unavoidable, being due to a rearrangement of one of the exchanges; but it would not interrupt the working of a single line. There are 70,000 subscribers in England, Scotland, and Ireland, 7,500 of whom are in London. These necessitate the keeping up of 540 exchanges, 25 of them being metropolitan. There are 1,283 public call offices, and 245,000,000 messages are despatched every year. The area of the London district covers upwards of 500 square miles. In future every line in London will be composed of a metallic circuit necessitating two wires. This alteration is rapidly being carried out without any interruption in the working of the lines affected. The National Telephone Company are at present completing in Lime-street the largest exchange in England. It is being built on a scale to accommodate 7,600 lines when fully occupied.

The Dover Central Station.—The question of lighting Dover by electricity has been before the Town Council for about 10 years. When the question came to be tackled at close quarters it was felt that the enterprise was too delicate for the Corporation to handle, and it was ultimately decided to transfer the powers of the provisional order to the Dover Electric Supply Company, which was formed last autumn with an authorised share capital of £50,000, the new company being assisted into existence by the Brush Electrical Engineering Company, who previously had the matter in hand, and who have entered into a contract to supply the electrical equipment. The company purchased the site of the station on the east of Park-street, and a contract was entered into with Mr. Herbert Stiff to erect the new station now in progress. The land secured for the station runs the whole length of Park-street, and adjoins the grounds of Brook House on the other side. The main building is 116ft. long and 72ft. wide; the boiler-house is 100ft. long and 42ft. wide; the machine-room is 100ft. long by 30ft. wide. There are also a testing-room, a Board-room and office, cloakroom, and lavatories. The boiler flue runs along the floor to the upper end, where it joins the base of the chimney. The contract for the whole of the building has been taken, as already mentioned, by Mr. Herbert Stiff, who has to finish it by August 13. The oversight of the work is entrusted on behalf of the Dover Electric Supply Company to Mr. Alfred Matthews, formerly a member of the Dover Town Council.

Ealing.—At a meeting of the Local Board last week, the Electric Lighting Committee reported that they had visited the electric lighting works, and expressed their satisfaction with the progress the works were making. The surveyor mentioned to the Board that a number of houses in the district, including two in the Grange-road (Beaumont House and Garth House), and others in Hanger-lane, had been, or were about to be, wired. In answer to a question the surveyor said that whether an installation of the light could be made in Mount-park and that neighbourhood would depend upon the number of householders in that vicinity who signified their willingness to take the light. The surveyor read a letter from a resident of Park-hill asking whether any steps were likely to be taken towards the introduction of the light into that locality, and suggesting the issue of a circular to owners and residents of property in the district as a means of ascertaining what amount of private lighting was likely to be required. This suggestion was adopted by the Board, and a resolution was passed directing the issue of a circular stating the cost of the new light, and asking whether its installation for the purposes of private lighting would be needed. The Board had again under consideration the draft of the conditions to be observed in the wiring of private premises for the supply of the electric light, and fixing the charge to be made for rent of meters and current. The former charge was 1s 6d. per quarter for any number of lamps up to 25 lamps of 8 c.p. each, with a fixed increase per quarter for every additional 25 lamps beyond that number; the charge for current was at the rate of 6d. per Board of Trade unit. These conditions and charges were approved. The Board then proceeded to discuss the question of the position in which the public street lamps to be erected under the electric lighting scheme should be placed along the main road from the western end of the Broadway (not including that thoroughfare itself) to the Hanwell boundary of the district.

Electric Lighting of St. Paul's Cathedral.—Major-General Webber has sent the following letter to the *Daily Telegraph*: "In your issue of this date I observe that you describe the experiment of lighting St. Paul's Cathedral on the 11th inst. as a 'dismal failure,' and 'that the distribution of light was irregular and insufficient'; also that 'the intensity of the shadows is said to have been positively gruesome.' As responsible, under the committee of the cathedral authorities, I may be regarded as the 'skilful electrician' who was consulted, and, therefore, trust you will permit me to correct the misapprehension under which your informant must have laboured. The experiment to which he refers was one of a series which have been made this year, the object of which has been to arrive at several conclusions on the question of cathedral lighting that have hitherto been obscure. Their objects have been to test (1) the comparative value of the arc and of the incandescent lamp as an illuminant in places used for public worship, especially with reference to the absorption of light by the stonework of St. Paul's; (2) the possibility of giving sufficient light, without standards or pendants, so that every individual in the congregation occupying so large a space as that under the dome of St. Paul's could read small print with ease, and also to ascertain the volume of light required to give that result; (3) the possibility at the same time of placing the light so that it would fulfil two conditions—namely, so that the glare of the incandescent portion of the lamps should not offend the eyes, either of the congregation looking eastward or of the occupants of the choir and chancel looking towards the west. It was proved conclusively by the experiments that these

Digitized by Google

difficult but essential conditions could be attained without cross shadows, and that the illumination was most regular and adequate within the area dealt with—namely, the floor space under the dome. A few other tests were made in isolated portions of the cathedral from which the general results, on a more extended scale, could be estimated, and possibly your informant was unintentionally misled by the partial character of those results (quite understood by the committee) into adversely criticising arrangements which, if permanently reproduced on an extended scale, will place our metropolitan cathedral in front of all other ecclesiastical edifices as the great example of how electricity as an illuminant can be applied artistically, scientifically, as well as economically."

Electricity in Mining Operations.—Messrs. Ernest Scott and Mountain, Limited, electrical and general engineers, Close Works, Newcastle-on-Tyne, have just completed for the Lothian Coal Company two large sets of electric pumping machinery, and a third set is to be added shortly. The present plant consists of two dynamos, each to give an output of 60,000 watts; two sets of three-throw ram pumps, each set to be capable of delivering 250 gallons of water per minute against a head of 650ft., each set to be driven by an electric motor of 60 h.p. Heavy-armoured cables are being used for conveying the current from the engine-room at bank to the pumps, which are placed underground. The same firm have in hand for Messrs. G. B. and T. E. Forster, for Cambois Colliery, Northumberland, seven sets of electric pumping machinery. The plant consists of horizontal engine, with triple expansion gear capable of developing 80 h.p., and a 50-unit Tyne shunt-wound dynamo working at an E.M.F. of 350 volts, together with conducting cable from the dynamo to the bottom of the shaft, with branch cables to the seven sets of pumps. This plan is interesting inasmuch as it is the first case in which electricity has entirely replaced rope-driven pumps, and particularly as the old pumps have been used, each pump being driven by an 8-h.p. electric motor through worm gear. The crankshaft on which the worm-wheel is placed takes the same position as the old shaft on which the wire rope was fitted. There is about 20 miles of cable in all underground leading to the various pumps. Each circuit, which is controlled from a junction-box, is fitted with a switch, so that the pumps can be stopped and started from various points. The same firm have in hand for Messrs. Strakers and Love a set of electric pumping machinery, consisting of horizontal engine of 125 i.h.p., a 55-unit Tyne shunt-wound dynamo, with overhead conducting cables, and a set of three-throw pumps, with rams 9in. diameter and 15in. stroke, delivering 300 gallons of water per minute through two miles of 6in. pipe, total head, including friction, being 420ft. In this instance a Tyne electric motor of 55 effective horse-power is used for driving the pumps. In the electric light department the firm are also extremely busy, and have in hand the lighting of the Edinburgh Roperie, with engine, dynamo to run 600 lights, and incandescent lamps throughout the Roperie. In a large private house in Kirkby Lonsdale, being built by Dr. W. T. Paget-Tomlinson, the plant consists of a Priestman oil engine of 22 h.p., a dynamo to run 200 lights, with accumulators, and about 260 lamps throughout the house. They have just completed for the Coltness Iron Company an installation consisting of three dynamos, two machines being used for lighting the pithead and workmen's cottages, the third for an electric pumping plant, the pumps being placed by the river and capable of delivering 120 gallons per minute against a head of 160ft. Lighting installations are being carried out by them at Shaw's Hotel, Grisland, for the s.s. "Aswanley," and at Seaton Delaval Colliery, together with an installation for Messrs. Jonas Brook and Bros., Feltham, which is just completed, consisting of two 800-light dynamos, and 1,400 incandescent lamps. In the engineering department the firm are busy, having in hand a large number of fire and bilge pumps for the torpedo destroyers, together with other engineering specialities.

Action for Telephone Rental.—On Wednesday, at the Sheffield County Court, before Judge Ellison, an action was brought by the National Telephone Company against Messrs. Morris and Matthew, chemical manufacturers, Doncaster and Stockwith-on-Trent, to recover £50, balance of rent due for telephone service. Plaintiffs were represented by Mr. T. E. Ellison (instructed by Messrs. Webster and Styring), and Mr. B. G. Wilkinson (instructed by Messrs. Parkin and Co., Doncaster), appeared for the defendants, who had filed a counterclaim for £50 damages arising from the defective working of the telephones. Defendants do not deny that the rent sued for was due under the contract between themselves and the plaintiff company, but they contended plaintiffs were not, under the special circumstances, entitled to it. Mr. Wilkinson, on behalf of the defendants, explained that in 1889 his clients were approached by the company with reference to putting up a telephone wire between their offices in Doncaster and their works at West Stockwith, about 20 miles away, and also a wire between the offices and the residence of Mr. Morris, the senior partner, who lived in the suburbs of Doncaster. The plaintiff company sent the contract to the defendants for signature, and with it was a letter in which the company stated, amongst other things, "We guarantee that the communication between your offices and works will be absolutely satisfactory to you, and that any repairs, should there be any, will be attended to at once by the company." It was on the faith of that strongly-worded assurance that defendants signed the agreement in March, 1889. Although it was said the wires would be laid in a few weeks, 12 months elapsed before the work was completed, and it was not until March, 1890, that the defendants were placed in possession of the service. From the very commencement the defendants were subject to great annoyance because of the imperfectness of the communication. In consequence of this the company allowed a deduction of £10 on the rental for the first year. During the succeeding three years the communication continued to be most unsatisfactory, and complaints were constantly made to the company—in fact, no less than 118 letters calling attention to this and requesting a remedy were sent—but with no result. Two years ago, or thereabouts, the company put up public wires for parties in other places on the poles used for defendants' private wires, and this added to the confusion, inasmuch as when defendants wished to speak from their offices to the works they would be interrupted by conversations between persons in Sheffield, Gainsborough, and other places. Defendants' contention was that the work in connection with laying down the telephonic service was unskilfully done. The company had almost continuously sent men to effect an improvement, but they did not succeed, and defendants' business was interfered with. Counsel went on to contend that the contract between defendants and plaintiffs was made from a company point of view, and that defendants, as business men, would not have signed such a one-sided document unless they had had some distinct assurance from the company such as was contained in the letter that the service would be satisfactory, and he contended that the guarantee became part of the contract. Several witnesses having been called on behalf of the defendants, all of whom bore out counsel's opening statement, it was intimated that to finish the case would occupy a long time, and it was therefore agreed to adjourn the further hearing to a date to be fixed.

A New Underground Conduit.—Mr. John Wilkinson, of 27, Rawcliffe-street, South Shore, Blackpool, who for nine years was a member of the Blackpool Town Council, has devised a system which he anticipates will prevent a recurrence of the annoying delays arising on electric tramways in consequence of accumulations of sand, soil, and sea-water, and the overflowing or bursts of the water-mains, resulting in the corrosion of the insulators and continual fusing, and short-circuiting in connection with the underground parts of the conduits or channels, which in time leads to the destruction of the electrical parts, also causing serious irregularities to the dynamos, engines, and other machinery at the works, and a stoppage of traffic until the necessary remedial measures have been taken. Through the slot or groove in the central channel there is refuse constantly entering, but he considers his invention a very feasible one, inasmuch that the conductor and the vital parts of the collector are both protected from injury from the causes mentioned above. An overhanging flange in the central channel covers the conductor and a part of the collector. We quote the following from a Blackpool paper: "Instead of the box which has now been introduced under Mr. Holroyd Smith's scheme, Mr. Wilkinson has made provision for an 'inner box rail.' The rail provided for by Mr. Wilkinson is rather broader than that at present in use. Within this rail is an 'inner box rail' made of handy and convenient lengths, so that it may easily be removed for examination of the conduit and the restoration of any of the electrical appliances. Under the old arrangement, in order to repair the conductor or to open the central channel, a large length of rail had to be removed. These operations have, under Mr. Wilkinson's scheme, been very greatly facilitated. The lengths can be easily taken up, and the whole of the mechanism and apparatus is at once exposed to view, so that any repairs can be carried out without any interference with the traffic. Of course the great feature of the design is the effect it is expected to have in combating the evils of accumulation of dust, but the dispatch with which repairs can be effected is also a very great point in its favour. The channel provided for is exactly similar to that of the Blackpool tramways, so that in case the necessity ever arose for the trial of a new system—a not very improbable emergency—if regarded favourably, Mr. Wilkinson's scheme might be adopted without any very great alterations. The copper conductors can be replaced in a very short time. The insulators are equally easy of access, and very little work is entailed in the substitution of new ones for those that may be broken, or in any way defective. The ex-councillor claims that his invention is especially adapted for the Blackpool Promenade; he maintains that it is a great advantage to be enabled to inspect the mechanism at any given point, and not at intervals as provided by a box system. Under his scheme, he points out, the whole of the line might be opened concurrently in order that repairs might be carried on with freedom, or the channel cleared without interference with the progress of the cars. But beyond this Mr. Wilkinson is considering the advisability of providing for a double conductor, one of which would be kept in reserve. He argues that this would be a great safeguard in regard to accidents or defects, for when one conductor failed the other conductor could be utilised, and it would not be necessary to suspend traffic at all. For several months past the inventor has had the matter under consideration, and he intends to submit his model to the Blackpool Corporation, in the hope that if there are further developments in connection with the tramways, a trial may be given to a scheme which he considers would be voted a success."

The Wolverhampton Central Station.—The Mayor of Wolverhampton (Alderman C. T. Mander) on Monday laid the foundation-stone of the municipal electric lighting works, which are situated in Commercial-road. The proceedings were of a formal character. Among those present were Aldermen W. H. Jones and J. Sanders; Councillors Shepherd, Jenks, Johnson, and J. J. Tate; and Messrs H. Brevitt (town clerk), T. Parker, F. H. Lewis (electrical engineer), A. P. Brevitt (architect), H. Willcock (builder), and J. T. Homer. The Mayor was presented by Mr. Brevitt with a silver trowel, bearing the following inscription: "Presented to the Right Worshipful the Mayor of Wolverhampton (Mr. Alderman Charles Tertius Mander, J.P.), by the architect, Archibald Paul Brevitt, on the occasion of his laying the foundation-stone of the Municipal

Digitized by Google

Electric Lighting Works, on Monday, the 21st of May, 1894." Subsequently the Mayor entertained a number of gentlemen to luncheon at the Victoria Hotel, and after the toast of "The Queen" had been honoured, his worship proposed "Success to the Electric Lighting Works of the Wolverhampton Corporation." He said the question of introducing the electric light into Wolverhampton was mentioned some years ago, but it was delayed by the Town Council, and probably no one was any the worse for the matter having been proceeded with slowly, inasmuch as during the last few years great strides had been made in the study of electric lighting, and by waiting the Wolverhampton Corporation had probably been able to introduce a system which they could not have initiated even four or five years ago. The plant which would be put down would be capable of generating sufficient current for 10,000 lamps, and this number could be increased to 15,000. There was a difference of opinion as to the relative cost of gas and electricity, but he believed that electric lighting was practically no more expensive than gas at 2s. 9d. per 1,000ft., and in the near future it would be less costly. Alderman W. H. Jones then submitted the toast of "The Architect, Builder, and Electrical Engineer, and Mr. Thomas Parker," which was responded to by those gentlemen. The capital outlay in connection with the cost of the undertaking is something like £30,000, and the parts of the town proposed to be lit up at the beginning are Darlington-street, Waterloo-road, Victoria-street, North-street, Cheapside, Exchange-street, Queen-square, Dudley-street, Snowhill, Lichfield-street, Princes-street, Five-ways, Queen-street, and the western end of Bilston-street. The boiler-house, which adjoins the engine-room, is to be 50ft. long, and the engine-house 78ft. long by 55ft. wide. The stack, circular in shape, will be 120ft. high. The contract for the buildings is in the hands of Messrs. H. Willcock and Co. Wolverhampton. The new buildings will occupy 1,330 square yards of land, in an area three times the size, which has been provided for the purpose, so that there will be plenty of room for any extension that may be required. In the boiler-house will be placed three Lancashire boilers, 30ft. long by 8ft. diameter, and they will be fitted with Green's economisers, while in the engine-house there will be placed one 125-h.p. and two 250-h.p. compound condensing engines. The smaller engine will drive by ropes a dynamo capable of supplying about 2,000 8-c.p. lamps, and the larger engines will similarly operate two dynamos, which will each be capable of supplying current for about 4,000 8-c.p lamps. The condensing-room will contain an Edward's ejector condenser and a Stanhope Water Engineering Company's water softener. The work of laying the mains has been commenced. The current generated by the dynamos will be sent under high pressure to the Town Hall, where the vault beneath the sessions court will be set apart as a central switch station, whence the current will be distributed under low pressure to sub-stations at the art gallery and free library. It has been decided to charge 6d. per unit.

PROVISIONAL PATENTS, 1894.

MAY 15.

9534. **An improved device for use with current meters, in observing the charging and discharging of electric accumulators.** Adolf Kolbe, 6, Lord-street, Liverpool.

9540. **Improvements in or relating to incandescent electric lamps.** Arthur Hungerford Pollen and Alan Donolly, 323, High Holborn, London.

MAY 16.

9565. **Improvements in the metal screw, belt, or other attachments for fixing insulators to carry electric wires.** Avon Gray, Featherstone-road, King's Heath, Birmingham.

9605. **Improvements in electric machines.** William Morris Mordey, 46, Lincoln's-inn-fields, London.

MAY 17.

9627. **Improvements in the mechanism of arc lamps.** Charles Neal Dexter, 114, Campsbourne-road, Hornsey, London.

9647. **Improvements in and connected with telephones.** James Nicolson, 22, Glasshouse-street, Regent-street, London.

9673. **Improvements in means for the distribution of alternating electric currents.** David Cook, 30, Lancaster-park, Richmond, Surrey

9690. **An improved electrical device for facilitating the lighting of gas.** Jean Jahnsson, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 18.

9743. **Improvements in electric conductors principally designed for lighting and heating purposes.** Ernest Bailey, 45, Southampton-buildings, Chancery lane, London.

9761. **Improvements in electrolytic apparatus.** Thomas Craney, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 19.

9763. **A horary meter for electric light, air, gas, water (compressed or not), and motive force.** Paul Cadot and Albert Charron, Bonnay-Charente, France. (Complete specification.)

9813. **Improvements in or applicable to meters or apparatus for supplying electricity, gas, or other substances in exchange for coin.** Percy Ruskin Allen, 46, Lincoln's-inn-fields, London.

9762. **Improvements on arc lamps.** James William Rogers, 7, Hargrave-park, Upper Holloway, London.

SPECIFICATIONS PUBLISHED.

1881.

2989. **Transmitting power by electricity.** Hopkinson. (Second edition)

1882.

4419.* **Electric arc lamps.** Brockie. (Amended specification.)

1890.

10595. **Measuring electrical energy.** Thomson. (Second edition.)

1893.

7594. **Electrolytical decomposition of chlorides, etc.** Lyte. (Second edition.)

8881. **Electric machine.** Howard.

9638. **Telephone apparatus and circuits.** Hall.

9639. **Telephone signalling apparatus and circuit.** Hall.

9640. **Electrical signalling apparatus and circuits.** Hall and Pickernell.

9753. **Electrical measuring instruments, etc.** Ayrton and Mather.

10396. **Electric conductors.** Dudgeon. (Société Anonyme John Cockerill.)

11842. **Electrical conductors.** Payne.

11890. **Telephones.** Rabbidge.

12437. **Electrically controlling lubricators.** Rosling and Matthews.

13491. **Semaphore signal apparatus.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

13492. **Operating signals by means of passing trains.** Siemens Bros. and Co.. Limited. (Siemens and Halske.)

13996. **Vehicles and electric locomotives for elevated railways.** Behr.

20887. **Incandescent lamps.** Ford and Barnes.

21379. **Electric light for photographic purposes.** Adamson.

1894.

4091. **Electric arc lamp carbons.** Jehl and Von Hardtmuth.

4333. **Suspending electric light, etc., fittings.** Johnson.

4909. **Targets and electrical indicating apparatus.** Collins and Jones.

5276. **Electric railways.** Cummins and Engelman.

5807. **Electrical safety fuse.** Edison and Swan United Electric Light Company, Limited, and Proctor.

NOTES.

The Bebe.—Our contemporary *Electricité* refers to the infant dynamo as a bébé.

Hotel-Lighting.—The Royal Palace Hotel, Kensington, is lighted throughout by electricity.

Electric Lighting at Gross-Becskerek.—It is proposed to light this Hungarian town electrically.

The Blackpool Tramway.—It is expected that the electric working of the tramway will be resumed very shortly.

Electric Lighting at Faverney.—This town of 1,500 inhabitants, in Haute-Saône, is to be lighted electrically.

Tolz-Krankenheil.—The streets, the Kur Hotel, the Hotel Sedlmair, and the Hotel Artman at this health resort are now lighted electrically.

Valence.—The Municipal Council of Valence, in the Drome district, has been approached with a view to an electric lighting concession being granted.

Charing Cross-Hampstead Railway.—The Charing Cross, Euston, and Hampstead Railway Bill has been read a third time in the House of Commons.

Borneo.—The British North Borneo Company have decided to connect the capital of their territory, Sandakan, by telegraph across country, a distance of over 200 miles.

Electric Tramway at Lubeck.—The opening is announced at Lübeck of an electric tramway. It has been constructed by the General Electricity Company of Berlin.

Not the "Electrical Engineer."—A contemporary asks those firms who gratuitously receive two copies of its issues to kindly give intimation of the fact to the publishers!

Porrentruy.—Two companies are desirous of undertaking the supply of electricity to this industrial town in the canton of Berne. The Municipality are enquiring into the matter.

Current for Motive Purposes at Altona.—The Altona Electricity Works have reduced their charge for current for motive purposes to 2·5pf. per 100 watts—or, say 3d. per unit.

Exhibition at Dover.—An electrical exhibition was held at the Municipal Buildings, Dover, on Friday and Saturday last, in connection with the introduction of the light into Dover.

The Brussels Tramway Company.—The receipts of this concern have increased considerably since the introduction of electric traction on the Uccle line and on the outer boulevards.

Competition.—The town of Arad (Hungary) invite by July 1 tenders for the erection and working of a central station. Particulars may be obtained of M. Salaez Gyula, the mayor of Arad.

Electricity at Ulm.—Messrs. Schuckert and Co., of Nuremberg, have received a 50 years' concession for the construction and working of a central electricity station and a tramway line.

Conversazione.—A students' conversazione was held at the City Guilds of London Institute, Leonard-street, on Thursday evening of last week. Prof. Silvanus Thompson delivered a lecture on "Polarised Light."

Electric Lighting at Havre.—The General Council of Havre have decided that the local electrical company shall be asked to light various streets and squares in the town by means of 80 10-ampere arc lamps.

A New Mitrailleuse.—It is reported that M. Turpin has devised a light mitrailleuse, worked by electricity, and with such rapidity that it can be charged and scatter balls as thick as hail in the twinkling of an eye.

Telephony and Telegraphy in Belgium.—The *Journal Télégraphique* of May 25 contains a large amount of statistical information concerning the working of the telegraphs and telephones in Belgium during 1892.

Electric Lighting in Frankfort-on-the-Maine.—Good progress is being made in connection with the erection of the municipal central electric lighting station. It is expected that it will be in working order by October 15.

Institute of Chemistry.—The annual dinner of the Institute of Chemistry of Great Britain and Ireland took place at St. James's Hall on Friday evening, Dr. W. J. Russell, F.R.S. (president of the institute), being in the chair.

Rock Drills.—Mr. J. S. Martin, H.M.'s Inspector of Mines for the South-Western District, suggests in his annual report that it is desirable for mineowners to give consideration to the operation of rock drills by electric power.

Thomson-Houston Company.—The Compagnie Française pour l'Exploitation des Procédés Thomson-Houston have decided to increase their share capital from £40,000 to £200,000 by the issue of 8,000 new shares of £20 each.

Water Power.—The works in course of construction at Chambéry for the utilisation of water power are being energetically pushed forward. The power available amounts to 1,400 h.p., this being in excess of that required for electric lighting purposes.

Graz.—Work is being energetically carried out in the laying of mains and the building of the central station, which it is expected will be completed at the latest by October. The new university buildings will have 1,000 incandescent lamps installed.

Electric Lighting at Weisswasser.—A central electric light station, which is being erected here by Messrs. Schuckert and Co., will be completed by September. The prices to be charged are 6·5pf. for lighting, and 2pf. for motive purposes per 100 watts.

Railway Station-Lighting in France.—The Northern Railway Company are installing the electric light at their stations at Albert (Somme) and at Cambrai (Nord). At the latter, two Breguet dynamos will be used, requiring steam power of 100 h.p.

Long-Distance Telephony in Germany.—Telephonic communication has been established between Hamburg and Hanover. The charge is 1s. for three minutes' conversation. For urgent messages the charge is thrice as much for the same period.

Economy of Electric Motors.—Mr. W. H. Panton, of Messrs. Dorman, Long, and Co., confirms the statement made by Mr. Bigge, referred to in another column, that the application of electric motors to their lighter machinery has saved his firm 30 to 35 tons of coal per week.

Electric Lighting at Montferrat.—The Municipal Council of this French town of 620 inhabitants have approved of an electric lighting scheme submitted by Messrs. Souchier and Co., of Marseilles. The municipal lighting is to comprise 14 16-c.p. lamps in the streets.

Traction in Switzerland.—The scheme for the construction of electric tramways at Chaux-de-Fonds has been deferred for the moment, so as to allow of a decision being arrived at concerning the proposed utilisation of the water

Digitized by Google

power of the Reuse for the operation of the generating plant.

Steam Traction.—We note that a company has now been formed in Paris under the title of the Société des Générateurs à Vaporisation Instantanée, système Serpollet, with offices at 27, Rue de Cloys, to operate tramways on the Serpollet steam traction system in competition with electric tramways.

Electric Traction at Hamburg.—Surveys are being made in connection with the high-level electric railway which was sanctioned some time ago, and which is to run from the Berlin Gate in Hamburg to the Victory monument at Altona. The line will in part be carried over the roofs of the houses.

Yet Another Exhibition.—Next year there will be held in Leipzig the seventh triennial exhibition of the metal goods, plate, and lighting industries. Particulars are obtainable from the Bureau für die VII. Allgemeine Fachausstellung des Verbandes Deutscher Klempner-Innungen, 6 Inselstrasse, Leipzig.

The Neuhausen Aluminium Works.—The result of the past year's working of this Company is very satisfactory. At the annual general meeting held lately at Frankfort-on-the-Maine a dividend of 10 per cent. was declared. It has been agreed to raise the capital of the Company from £400,000 to £440,000.

Electric Railway in Denmark.—Application has been made to the Government for a concession for an electric railway between Klampenborg and Humlebök on the Sound, which places are about 16 miles apart. The line is intended chiefly for passengers, but it is also proposed to carry a limited amount of goods.

The Land of Bliss.—The Americans have a lot to boast about, and so have we; but if the Metropolitan Traction Company of New York introduce, as is stated, the conduit system as employed at Budapest, this will show that even in electric traction our American friends do not "lick creation" when they have to come to Europe for an open-conduit system.

Northern Society of Electrical Engineers.—We are glad to learn from our New York namesake that the Northern Society of Electrical Engineers is seeking recruits in the United States. At all events, that is the conclusion we have arrived at from the fact that the rules, list of members, etc., have reached the United States before they have arrived in the Metropolis.

Feldkirchen (Carinthia).—An electric installation for 500 incandescent lamps simultaneously alight is to be carried out here. There will be two central stations working on a joint system of conductors. The stations will be about 900 yards distant from each other. There will be a 25-h.p. turbine at each. The work is to be carried out by Messrs. B. Egger and Co., of Vienna and Budapest.

Yaller Dogs in China.—A correspondent who has just returned from China informs us that while in that country he was compelled to eat "yaller dog." The only effect upon his constitution was, he says, that it made him feel a little flat—as if he had been standing at a window watching sheet lightning playing harmlessly about the heavens. We deeply sympathise with our correspondent.

The New Anglo-American Cable.—The steamer "Britannia," belonging to the Telegraph Maintenance Company, has arrived in Valencia Harbour heavily laden with cable for the purpose of laying the Irish shore end of the new Anglo-American cable from Valencia Island, where the offices of the Anglo-American Cable Company are situated. The new cable will contain 200lb. of copper per mile more than any cable hitherto laid across the Atlantic to the New World.

Electricity v. Gas.—At a recent meeting of the Ulverston Local Board, on the report of the Water and Gas Committee being brought up, it was mentioned that the Lonsdale Iron Company and the Ulverston Paperworks had been offered a reduction of 10 per cent. in the price of their gas, but both firms had now adopted the electric light as the cheapest and most efficient illuminant for their purpose.

The British Association.—As stated in our issue of 4th ult., the British Association will open their sixty-fourth meeting at Oxford on August 8. We have already given the outline of the programme. Authors are now reminded that they should prepare an abstract of their memoirs of a length suitable for insertion in the published *Transactions* of the association to be sent, together with the original memoir, on or before July 11, addressed "General Secretaries, British Association, Burlington House, London, W. For Section ——."

The Lighting of the Bourbon Palace.—The French Chamber of Deputies have under consideration the lighting of the Bourbon Palace, it being proposed to devote a sum of 500,000f., or say £20,000, on machinery for an electric light installation. At present the Chamber pays 122,000f. a year for the lighting. With the expense of the plant once paid, the annual cost for lighting would not be over 72,000f., thereby effecting a saving of 50,000f., or £2,000, which would allow of the initial outlay being recouped in 10 years.

Electric Lighting at Urach.—The Municipality of this Wurtemberg town have decided to introduce the electric light. It is intended to utilise the water power of a saw-mill in the neighbourhood. The streets will be lighted by incandescent lamps, and experiments with such have already been made in the market place. It is also proposed to supply electric power for small industries. As there is no gas company in the place, it is expected that there will be a good demand for light. The Esslingen Machinery Works will carry out the installation.

Imitation.—It is wonderful how when one person has devised any system or apparatus, others subsequently come forward and invent the same thing and call it an improvement. For instance, since Mr. Lineff devised his closed-conduit method of electric traction, plenty of people, especially in the United States, have come forward with similar systems, and now MM. Claret and Wuilleumier according to the *Génie Civil*, have invented a method of electric traction about to be tested in Lyons, and which from the description appears to be the same as the Lineff.

The Paris Underground Electric Railway.—In our last issue we gave particulars as to the progress then made in the promotion of this scheme. The Railway Committee of the Chamber of Deputies have now heard evidence, and have approved of the project by 12 votes to 2. The two opponents are Messrs. Boudenoot and Chavoix, both of whom are engineers, and who hold that the scheme is not practicable. The Railway Committee, though only 12 took part in this first vote, consists of 33 members, and the result arrived at will not prejudice in any way the final decision.

Cable Nomenclature.—The fifth edition of the "Nomenclature of Cables," published on April 25, 1892, by the *Journal Télégraphique*, has now been exhausted. The Bureau International des Administrations Télégraphiques, of Berne, is now preparing a new edition which is expected to be ready for publication in that journal in October next. It is intended in the new edition to sub-

Digitized by Google

stitute for the lengths in nautical miles of cables and conductors, lengths in kilometres, so that the figures will be in accord with those issued periodically in that journal concerning telegraphic statistics.

The Queen's Birthday Celebration.—On the occasion of the celebration of the Queen's birthday on Saturday, some novel devices in electric lighting were exhibited in the West-end. At the Queen's birthday party last year the Foreign Office was lighted by electricity. That was an improvement due to the private enterprise of Lord Rosebery. Encouraged by the success that attended the experiment, the Board of Works subsequently authorised, as stated in our last issue, the permanent installation of the light, which on Saturday shone over the assembly which crowded the Foreign Office.

Lighting of Railway Lines.—The *Moniteur Industriel*, in referring to the dropping of various kinds of merchandise from railway goods wagons in France, suggests that for the protection of express trains running along the same lines, the tracks should be lighted by electricity. This is not a bad idea—for France. Here in England we do not drop goods in the manner mentioned; we only drop bad debts and bad acquaintances. At the same time, the lighting of railway tracks could, seriously speaking—or writing, should we say—be easily effected by the use of large electric headlights on the locomotives, a kind of industrial monitor.

Electric Lighting at Gisors (Eure).—The gas company in this French town some time ago declined to establish electric lighting plant, although bound to do so by the terms of their concession. A local merchant then made a proposal to the Municipality. He acquired ground opposite the gasworks and established a central station in the short period of two months. There is a multitubular boiler, a 70-h.p. Weyer and Richemonde steam-engine, and a Gramme dynamo having an output of 300 amperes at 120 volts. Overhead conductors and the two-wire system are employed. There are now about 700 lamps installed.

Electricity at Crone-on-the-Brahe.—It has been decided to erect a central electricity station for the supply of current for lighting and power purposes. Water power is available to the extent of 350 h.p. It is proposed that the station should have a capacity for the supply of 2,000 incandescent lamps of 16 c.p. simultaneously in operation, or their equivalent in arc lamps, and for the supply of current to motors a total of 80 h.p. The question is also being considered of an electric railway of normal gauge, about 6½ miles in length, from Crone to the Maximilianowo railway station, to be supplied with current from the central station.

Self-Contained Vehicles.—As we have previously mentioned, a competition of self-contained vehicles has been promoted by the *Petit Journal* of Paris, and will take place in the latter half of next month. There are 102 entries, but of these only a few in which electromotors are to be employed. These are as follows: An electric phaeton to carry four, by M. Monges, of Paris; M. P. Geoffrey's carriage; a carriage for two, of Count Carli, an Italian deputy; a carriage for six, by M. Soudais, of Fontenay-Sous-Bois, with "a semi-electric motor" (*sic*); and an electric carriage by Mr. Garrard, who is described as an Englishman. Most of the vehicles will be actuated by petroleum motors, this source of energy being the readiest obtainable on the route to be taken.

Construction of Magnetic Apparatus.—A paper has been read by M. S. Wild before the Academy of Science in St. Petersburg on the construction of magnetic instruments. The paper comprised four sections. The first dealt with the results of experiments showing that metallic wire is preferable to silk thread for the suspension of magnets; the second with the degree of accuracy of the readings when instruments are placed in buildings constructed of material containing iron, such as ordinary red brick; in the third part the author described a little magnetometer for the determination of the value of the horizontal component of terrestrial magnetism; and the fourth section dealt with various improvements on the magnetometer made by M. Wild.

Private Telephones.—Our attention has been called to a system of internal telephone installation, adapted, for instance, to large offices, works, and other private buildings, whereby the various departments are enabled to obtain immediate and direct communication with each other, at the same time doing away with the necessity for a central switchboard and attendant. This method is being developed by the Private Wire and Telephone Installation Company, of 110, Cannon-street, E.C., who have already fitted the apparatus with telephones throughout the *Times* offices, and are engaged on a similar contract for the new offices of the *Daily Chronicle*. At the offices of the latter, instruments are being fitted in eight departments. The wiring between the various points is taken from every to every other point, each station being provided with a small plug and keyboard, so that each point can call up any other direct.

Electrically-Welded Continuous Rails.—According to the *Engineering News*, continuous rails, electrically welded, are to be used on the Baden and St. Louis Electric Railway, and the Johnson Company, of Johnstown, Pa., is doing the welding with its special car. In this connection the *Street Railway Gazette* states that the West End Company does not regard the electric welding of rail joints as successful so far as it has been applied in Boston. Trouble has been constantly experienced with the breaking of the joints. The company, however, seems to consider its test of welded joints insufficient to justify any unfavourable conclusions, and within a short time the Johnson Company will make a new experiment. In this case a different style of weld will be tested which, it is believed, will prove far stronger and therefore much more successful. With the heavy rolling-stock owned by the West End the best joints available are urgently needed.

Variable Speed Gear for Electric Traction.—We understand that the Gas Traction Company has secured an exclusive license to use the Beaumont variable power gear for gas and oil traction purposes on tramways and light railways. It is to be hoped that English electric traction interests will not allow this key to successful electric traction to slip into the hands of an enterprising foreign firm. Its value has been recognised by mechanical and electrical engineers, although some electricians still adhere to the idea that the difficulties can be surmounted by electrical rather than by mechanical means. This, as we have before pointed out, is only partly true, for no electrical means reduces the power required to be provided for starting, or the size and weight of the motors required for ascending hills. We illustrated this gear last September, and the necessity for it has been again and again pointed out, and most recently in the paper by Mr. David L. Barnes.

Modification of the Lipmann Electrometer.—Those who have made use of the Lipmann electrometer know that this apparatus works regularly, provided that it is used daily. If the appliance is allowed to rest for a length of time, the capilliary tube becomes choked, and the mercury contained therein becomes idle. M. Limb has just overcome this defect by an ingenious modification of the instrument. The cause of deterioration being entirely

Digitized by Google

due to the presence of the mercury in the tube, it is only necessary to remove the mercury from it during experiments. This result is obtained by an arrangement identical to that employed in some barometers. The tube is connected to an indiarubber pipe, terminating in a glass funnel, which is easily movable. At the end of the experiment the mercury is replaced. Another modification, according to *L'Industrie Electrique*, consists in providing the microscope with a projection cone, which allows of readings being taken with the naked eye.

An Electric Log.—Admiral Fleuriais, of the French navy, brought out an electric log which was tried on the "Magicienne" in 1878. It may be described as a small watermill with a wheel consisting of cross-arms tipped with cups like the anemometer of Robinson. There were two sets of four cups mounted on the ends of the same axle, and as they revolved in the water while the ship moved, a contact on the axle interrupted an electric current flowing through a wire between the ship and the log, and sounded a telephone. The note given out by the telephone was a measure of the number of revolutions per minute of the log and the speed of the ship. At high speeds, however, the ear was not quick at recognising the note, and Admiral Fleuriais has substituted for the telephone an electric bell, which is struck every 24 revolutions of the mill wheel or vanes. By timing the interval between two strokes of the bell the speed of the ship is obtained. The apparatus has been tried on board the "Ocean" and other men-of-war, and recently adopted by the Minister of Marine.

Cable Interruptions and Restorations of Lines. The following table is self-explanatory:

	Interrupted.	Restored.
Cable, Brest — St. Pierre, belonging to Anglo Company.....	April 6, 1893.	Not yet.
Cable, Paramaribo — Cayenne	Oct. 25, 1893.	Not yet.

Power Distribution by Electricity, Water, and Gas.—The next ordinary meeting of the Society of Engineers will be held at the Town Hall, Westminster, S.W., on Monday next. A paper will be read on "Power Distribution by Electricity, Water, and Gas," by Mr. Ed. C. de Segundo, of which the following is a synopsis: Definitions of "efficiency"—Efficiency of steam-engine and boiler—Efficiency of gas-engine and generator—Thermal value of town gas—Carnot's function cannot be applied easily to gas-engine performance—Maximum probable temperature attained in gas-engine cylinder—Chief faults in gas-engines of present day—Efficiency of individual portions of plant in electric central generating stations—Efficiency of old plant in practice—Similar considerations relative to hydraulic power stations—Steam-engine not so wasteful a heat machine as usually considered—Initial form of energy available, and final form required as factors in economy of distributing systems—Hydro-electric scheme—Comparison with purely electric distribution—Scheme for gas-engine electric sub-stations for electric lighting of towns—Efficiency of gas burner—Efficiency of electric burner—Others reasons in favour of this scheme—Example of utilisation of existing hydraulic power supply for private electric light installations—Conclusion.

Alternate-Current Electrolysis.—A paper on this subject is given in the *Proceedings* of the Royal Society by Dr. J. Hopkinson and Messrs. E. Wilson and F. Lydall. The paper contains the results of a number of experiments, the object of which was to determine (1) the dissipation of energy due to electrolytic hysteresis, and (2) the quantity of an ion per square centimetre of an electrode necessary to change the properties of the electrode to that of the ion during alternate-current electrolysis. The experiments were carried out by passing an alternate current through an ordinary non-inductive resistance and through an electrolyte, and then measuring the differences of potential at the extremities of these two resistances at different phases of the current. Curves of current and potential differences with different frequency are given, as well as curves showing the dissipation of energy per cycle. As a result of the experiments, it was found that with platinum electrodes of 150 square centimetres area, the ion being hydrogen, the maximum E.M.F. due to polarisation was reached when one-tenth of coulomb had passed through the cell—that is, when 0·00001 gramme of hydrogen had been liberated. It hence appears that 0·00000007 gramme of hydrogen is sufficient to polarise one square centimetre of platinum. Assuming the density of the hydrogen to be comparable with that of liquids, the thickness of the film of hydrogen necessary is of the same order as this number—0·00000007cm.—a number comparable with the distance between the molecules.

Lightning Stroke. — Ball lightning, the *fulmen globulare* of the older meteorologists, is the most dangerous and destructive of the forms which lightning is known to assume. Fortunately, however, it is the rarest. A narrow escape from death by its stroke, the *Lancet* says, occurred lately in the person of a distinguished surgeon of the Belgian school, Dr. L. Dandois, Professor of Surgery in the University of Louvain, who had gone to the neighbouring town of Linden to visit a patient, and on his return, having alighted from the train to continue his homeward journey by road, was overtaken by a heavy thunderstorm. The sky became as dark as at midnight, so as to make it difficult for him to avoid the telegraph poles standing at intervals along his path. In a few minutes a fireball, as he described it, descended on him, its stroke hurling him off the road, across the ditch that ran parallel to it, and landing him in the adjacent field. He was holding a large umbrella at the time, holding it with both hands by the wooden stick, which was of uncommon thickness. On coming to himself after the shock he found the umbrella cover completely burnt off its steel framework, the steel itself being twisted into every sort of shape. The wooden handle had no doubt saved his life—had it been of metal Dr. Dandois is convinced that he must have been killed instantaneously. As it was, fully 10 minutes elapsed before he recovered the use of his arms and legs, benumbed as they were with the shock. Ultimately he was able to resume his walk homeward.

Volk's Electric Railway.—A four minutes' service is now maintained on this electric railway, four cars being in operation. There are two new saloon cars; and a 20-h.p. Tangyes engine and a 26-unit Kapp dynamo, made by Messrs. Johnson and Phillips, have been put down at

Digitized by Google

the generating station. By altering the switch the E.M.F. can be made to rise with the current, so that the E.M.F. on the line does not drop when more cars are running, as it would otherwise do, owing to the extra loss in the leads. We understand that over 8,000 people travelled on the railway on Whit Monday. The cars are worked two running and two loading all the time, thus increasing the capacity 60 per cent. without putting any more strain on the machinery. The old generating plant has been retained as a stand-by, or as a reserve. In the case of the Brighton and Rottingdean Railway, we are informed that the whole of the material has been delivered, and the rocks, etc., are now being levelled preparatory to laying the rails. The rails are 53½lb. to the yard, and are made of specially rolled steel. The track will consist of four rails, owing to the great width and capacity of resisting the force of the sea. The cars themselves will be constructed like the deck of a saloon, after the pattern of a steamship, affording room for passengers to walk about. Each car will carry about 150 persons. The piles for the jetty are all driven at the Brighton end. All the iron and steel work is nearly ready for delivery for the jetties at both ends. It is expected that the railway will be in working order for next summer's season. All the detailed plans have been passed by the Board of Trade.

Electric Phenomena During Thunderstorms.—Mr. C. S. Du Riche Preller, writing from Baden to the *Standard* of yesterday's date, says: "Some exciting and horribly beautiful, but also very dangerous, electric phenomena were observed in the picturesque canton of St. Gall, on the evening of the 25th inst., during a thunderstorm of extraordinary violence, accompanied by a deluge of rain. The large 'village' of Gossau, about seven miles from the town of St. Gall, derives its electric supply for lighting and motive power for industrial purposes from a hydro-electrical central station, situated at a distance of eight miles, by a high-tension transmission, with transformer stations in the village. The thunderstorm, accompanied by violent lightning discharges, passed over the place at 5 p.m., and then, driven back by a change of wind, returned, and lasted for several hours. Soon after 5 p.m. all the electric lights went out spontaneously, but the place was illuminated by violent sparks and flashes, which were emitted by the overhead wire system, and ran along the conductors. These phenomena reached their height at the principal transformer station, close to an hotel; for here the high-pressure current escaped from the conductors to earth—viz., the ground saturated with rain—the effect being a succession of flashes or continuous blaze, which so endangered the building that the fire brigade had to be called out to protect it. These phenomena continued for several hours, till the electric supply was cut off at the central station, a special messenger on horseback having been despatched thither, for, wonderful to relate, the installation was as yet without telephonic communication. The lightning struck several houses in the village, though without doing harm; but a young man of powerful build, and of local position and great promise—for he was to have been elected mayor on the very next day—inadvertently touched one of the electric cables, and was instantly killed. The inhabitants of the place might have been spared the terror of these phenomena, and probably no human life would have been lost, if the electric supply had been cut off during the altogether exceptional thunderstorm, as should always be done—and in the United States is done on some electric tramways—in districts visited by violent atmospheric discharges, and where overhead wires are used. Only last summer I witnessed a similar occurrence on the Mont Salève electric railway, near Geneva, where the lightning struck the feed-conductor of the line, and thence found its way along the transmission cables to the central station, fully two miles distant, where it passed through the lightning arrester and burnt out one of the huge 1,000-h.p. dynamos. In this case, too, the lightning discharge was only the indirect cause, the direct cause being that the dynamo was running at the time—viz., that the current followed the discharge through the not quite perfect lightning arrester and 'short-circuited' the dynamo.

The Budapest Electric Tramways.—Some little time ago Alderman Ward, a member of the Leeds County Council, being over in Vienna on business, paid a visit to Budapest, with a view to seeing the system of electric tramways there in use, and he has favoured a Leeds paper with an account of what he saw. The Budapest electric tramway was first begun some six or seven years ago by Messrs. Siemens and Halske, and when it had been completed, so far as the present lines are concerned, they floated it as a company, with a capital of 4,000,000fl., which in English money is a little over £330,000. The company in the first year of its existence paid a dividend of 7 per cent. on its capital, and last year it paid 8 per cent., and the shares on the market to-day stand at 225fl. for every 100fl. invested. The power station is centrally situated, and from this point all the lines are worked. The total capacity at the company's disposal represents 1,750 h.p., which means that they possess a duplicate service of dynamos and engines in the event of a breakdown. On ordinary weekdays about 600 h.p. is required to work the traffic, but on Sundays—the continental holiday-making day—from 800 h.p. to 900 h.p. is required. The fare charged is six kreutzers for one length; if a change is made, taking an additional line, the charge is eight kreutzers; but if a double change is made, then 10 kreutzers is the fare. This means that for about 2d. English money a passenger may travel six to seven miles. The total length of the lines laid down on the conduit system is about 30 kilometres, or 18½ English miles. There is also a short distance of tramway on the overhead system, but this will be reconstructed on the conduit system as soon as convenient. At first the company experienced some little difficulty in working the lines, occasioned by mischievous people interrupting the electric current by putting a piece of metal down the conduit, but this form of amusement did not last long, and they have experienced no trouble of late. Slight interruption has also been met with from drifting snow, but it has never been of any serious duration, from half to three-quarters of an hour always sufficing to clear away the obstruction. In the low-lying portions of the city heavy rains have also occasioned slight difficulty, owing to the sewers not having sufficient capacity to take off the surface water which has flooded back into the conduit. But, with these slight drawbacks, the system works as smoothly as can be wished. Each carriage is constructed to carry 32 persons, but as no by-laws exist against overcrowding, standing room is permitted, and so on occasions cars may be seen with from 60 to 70 people in them. Each car, including the motor, weighs from 4½ to 5 tons, and cost about £500. The system is most popular in Budapest, and last year the company carried no less than 12½ million passengers, which practically means that, taking an average, each individual inhabitant used the cars 21 times in the course of the year. This year, however, the company expect to overtop these figures by 2,000,000. The cost of construction per kilometre, including the power station, workshops, waiting-rooms, cars, etc., is stated to be 95,000fl., or say about £13,350 per English mile.

AUTOMATIC ELECTRIC SIGNALS.

The only instance, we think, of automatic electric signalling at present used in this country is the method invented by Mr. I. A. Timmis, and employed on the Liverpool Overhead Railway. For many reasons, the Board of Trade—as the supervising department of all railway operation systems—has rightly set itself against the adoption of automatic working until at least an equal if not greater degree of safety is obtained with absolute certainty by its use, as compared with the employment of human motive power in the shape of signalmen. Judging, however, by the results obtained on the Liverpool line, and by the experience of American railroads—where automatic block working is in quite considerable service—the time has now come when the element of human fallibility in signalmen is likely to average out somewhat greater than the possibility of failure in the electric or other automatic mechanism, and seeing that a failure, whenever it occurs, may be caused always to tend towards safety with the latter system rather than towards danger as it often does with the former, there is the more reason for adopting any reliable automatic appliance, especially in view of its saving in cost of operation.

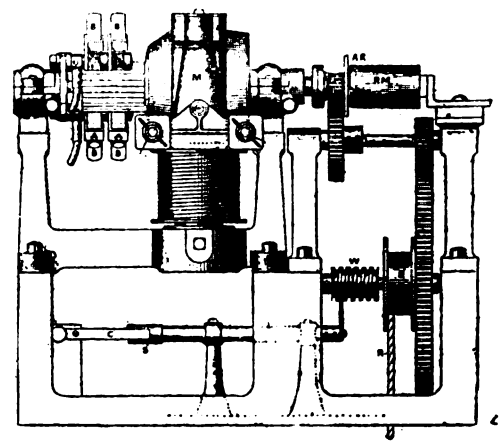
Of course, the ultimate action of an electric signal is due to the use of a magnetising force, in whatever way this be ultimately applied. On the Liverpool line, for instance, Mr. Timmis uses the pull of a specially-designed magnet itself to actuate the signal lever and clear the line, or the reverse. For many reasons, such a method has strong recommendations; its directness, reliability, and simple design are all points of great importance in assessing its standard of merit, and probably will continue to give it a leading position amongst such appliances. There are, however, other devices and methods of application possible for achieving the same end, and we illustrate in the annexed engraving an arrangement which has had considerable service on American railways, with, it is stated, satisfactory results.

One of these appliances consists of a small electric motor, which is operated by a battery of ten or a dozen Edison-Lalande cells, the circuit being made or broken in the usual way by the trains themselves as they pass over treadles or contacts on the line. When the current thus traverses the motor armature, the latter rotates, and through some gear wheels actuates a drum. Upon this is wound up a short length of fine wire rope connected to a rod or lever, which throws the semaphore arm down—the reverse action—*i.e.*, unwinding the wire rope—allowing a counterweight to pull the arm into the danger position again.

This apparatus is designed by Mr. J. W. Lattig, of the Lehigh Valley Railroad, and manufactured by the National Switch and Signal Company. In the method of installation recommended by the makers, both a line battery and a local battery working the signal are employed. These are normally at rest, the circuits being open; the signals stand in the "danger" position, being held there by the counterweights. When a train approaches a point where it is desirable to obtain the signal indication (and this point may be placed at any convenient distance before the signal is reached), an extension of the line or track circuit, either by overhead wire or cable, is closed by any of the usual contact-making devices, either electrical or mechanical. Provided the section ahead is unoccupied, the track circuit being thus closed, a current is transmitted through the rails from the extreme end of the section in advance and energises a relay controlling the local battery circuit, which being thus closed, the local battery current at once passes through the motor, setting it in motion, as already described.

After the motor has actuated the signal, its current, by an ingenious arrangement of worm gear, is then shunted to a releasing magnet. This grasps a circular armature, upon the spindle of which slides the motor pinion, and this being firmly held, prevents unwinding of the rope so long as the track circuit energising the relay remains unbroken. When, however, this circuit is interrupted, or the current is short circuited by the train entering the section so as to demagnetise the relay, the releasing magnet is de-energised, and the motor circuit broken at the same time. This allows the semaphore arm to return to its normal (danger) position, the gearing and motor revolving backward as the rope unwinds from the drum. Everything being now in normal position, all circuits open and the semaphore at danger, no further movement takes place until the approach of the next train, when, if the preceding train has not cleared the section which the signal controls, no "line clear" signal is obtained, although the train may have closed the track circuit at the point where the operation of the signal is effected.

In the illustration showing the elevation of the motor mechanism, M is the motor, R M the releasing magnet, with the circular armature, A L, attached to the sliding pinion, feathered on the shaft of the motor so that a free movement of the armature, A R, is permitted. When the current is shunted to the releasing magnet, R M, the pinion is held from rotating by the armature, A R, being firmly attracted to the magnet, thus preventing a backward movement of the gearing while the signal is being held in the clear position.



The pinion operates, through other gear wheels, the drum, D, upon which the rope, R, is wound; at the same time the worm gear, W, by means of an arm and rod to which it is attached, withdraws the contact, S, from between the springs, C C, thus opening the motor circuit and at the same time shunting the main battery current to the releasing magnet, R M, which, as above stated, acts like a pawl to hold the gearing motionless while the semaphore shows "line clear." The action of the batteries thus only continues during the interval of time elapsing from the moment when the train closes the track circuit until the signal is passed and the relay current is short-circuited by the entrance of the train upon the section. The signal may either be located at the entrance of the section or it may be placed a certain distance within the preceding section, so that the return of the signal to the danger position need not take place until the train has passed a certain prescribed distance beyond the signal-post, which, of course, so far as the engine-driver is concerned, marks the limit of the block section.

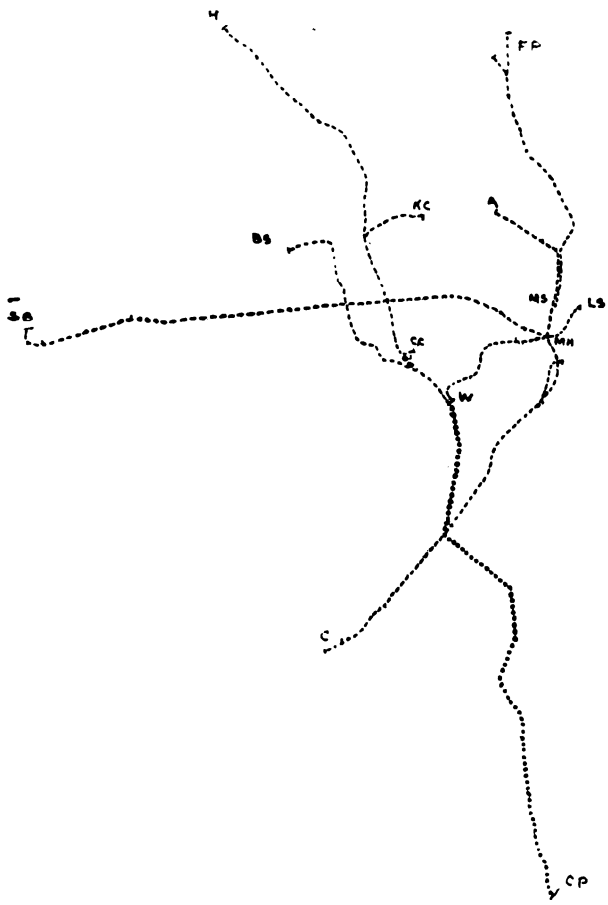
The maximum speed of operating the signal is two or three seconds; then the motor circuit is shunted, and but a fraction of the current used for the holding magnet until the train reaches the signal.

LONDON UNDERGROUND RAILWAYS.

Apparently the Waterloo and City line is at present the only one of the many projected and authorised Greathead tunnel electric railways which will achieve an early completion. The Central London line, like Scotland, "stands where she did." An extension of time limit for its completion has been obtained from Parliament; all the necessary arrangements have been entered into with local authorities and other interests along the line of route; the promoters are amply satisfied with the powers of electric working to give them, the public, and the shareholders complete satisfaction in every respect; and sufficient capital for construction and equipment is at hand and obtainable when necessary. No decisive step, however, has been

Digitized by Google

taken, and no contracts as yet entered into, the promoters wishing to choose a moment for developing the project that shall be the most expedient possible. Somewhat similar conditions govern also the new works of the City and South London line, though doubtless these will at once be undertaken as soon as the necessary financial arrangements can be made. The ill-fated Hampstead and Charing Cross line will again come before the public at a later date in a reorganised and greatly improved form, and it is much to be hoped that more substantial support will then be accorded to the project. Meantime, it may not be out of place to put before the promoters of this line the question of so far increasing its scope, and consequent value, as to carry it beyond the River Thames, through the South of London, to the Crystal Palace district. At the present moment it actually takes an unfortunate traveller across London the same time to pass, say, from Brixton or Sydenham to Hampstead, as would suffice for a railway journey to Leicester or Bristol from the Metropolis. The Crystal Palace has by no means an overplus of ways by which it may be reached conveniently even from the City or West-end, apart from the North of London, and although additional parliamentary powers would



of course be required for such an extension as that now proposed, the suggestion is well worth being considered in all its bearings. The other two lines authorised—viz., the Baker-street to Waterloo, and the Finsbury Park to Moorgate-street—are still in the chrysalid state, but we understand that they will shortly emerge from this into a more active condition. The matter of a junction between the former and the proposed extension of the Hampstead line southwards from Charing Cross, would probably also be worth consideration. Indeed, the new underground system of London, on the Greathead system and worked electrically, appears to be already gradually tending towards the form of a double centre—the Mansion House and Waterloo respectively—from which radiate arms and branches in all directions. This is shown by the annexed diagram, which represents the railways thus mentioned: the dotted lines give the routes followed, the termini being respectively Finsbury Park (F. P.,) The Angel (A.), Moorgate-street (M. S.), Liverpool-street (L. S.), Mansion House (M. H.), Waterloo (W.), Charing Cross (C. C.), King's Cross (K. C.), Hampstead (H.), Baker-street (B. S.), Shepherd's Bush (S. B.), and Stockwell (S.). The suggested extension to the Crystal Palace (C. P.) is represented by the line of small circles; this shows very clearly the comparative ease with which the Hampstead line might be carried on southwards across the river to Sydenham, either through districts not very well served at present—as given on the diagram—or else passing through the Clapham terminus of the South London line, and then onwards to the Crystal Palace. This is a longer route, but would give a better arrangement of lines, unless connection is made, say, at The Elephant and Castle, between the lines where they cross in the diagram.

ON THE SUBDIVISION AND DISTRIBUTION OF ARTIFICIAL SOURCES OF ILLUMINATION.*

BY PROF. WILLIAM A. ANTHONY.

It is a well-recognised principle that to illuminate evenly a given area by means of an artificial source, it is necessary that this source should consist of numerous small sources distributed over the area. In carrying out this principle it is usual to divide the area to be lighted into squares, and place a lamp in the centre of each square, as shown in Fig. 1, where each lamp is represented by the sign ×. In order to study the distribution of light by this arrangement of lamps, I have computed the illumination at the central point of the

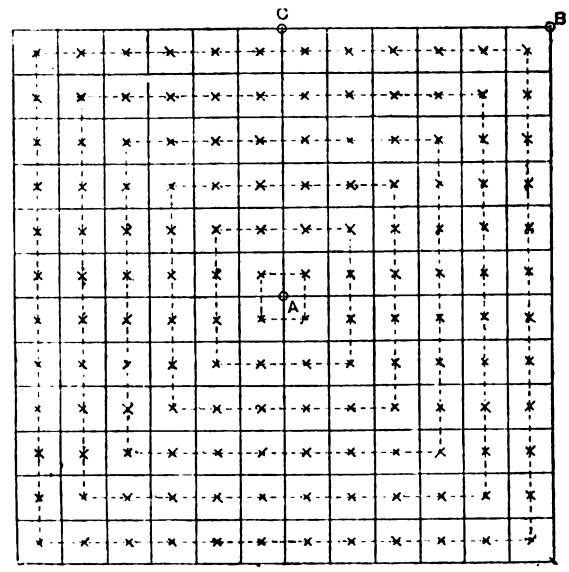


FIG. 1.

figure due to the lamps situated upon the boundaries of each of the squares represented by the dotted lines, the illumination produced by the lamps on the smallest square being taken as unity. The following table gives the values up to the twelfth square, twice the number represented in Fig. 1, and corresponding, therefore, to an installation in which four times as many lamps are used:

I.	II.	III.	IV.	V.
1	1·000	1·000	4	4
2	·511	1·511	12	16
3	·312	1·823	20	36
4	·223	2·046	28	64
5	·174	2·220	36	100
6	·143	2·363	44	144
7	·121	2·484	52	196
8	·104	2·588	60	256
9	·092	2·680	68	324
10	·083	2·763	76	400
11	·075	2·838	84	484
12	·067	2·905	92	576

Column I. gives the designating number of each square counting outward from the central point. Column II. gives the illumination at the centre due to the lamps located on each boundary. Column III. gives the total illumination at

* A paper read at the eleventh general meeting of the American Institute of Electrical Engineers, Philadelphia, May 15, 1894.

Digitized by Google

the centre due to the lamps included within and upon each boundary. Column IV. gives the number of lamps situated upon each boundary. Column V. gives the total number of lamps.

It is seen from the table that the twelfth series, which consists of 92 lamps, gives at the centre less than 7 per cent. as much light as the first series of four lamps, and contributes only about 2½ per cent. to the total illumination at the centre. This arrangement of the lamps does not give an even distribution of light over the entire area, as will be evident from a consideration of the illumination upon the outside boundaries of the space. It is evident that the point B at the corner of Fig. 1 receives one-fourth as much light as it would do if it were the centre of an area four times as large, and lighted by four times as many, or 576 lights. But the illumination at the centre of such an area as seen by the table is 2·905. The illumination at B is, therefore, 2·905 ÷ 4 or ·726, while the illumination at A from the sixth line of the table is 2·363. The illumination at B is then less than one-third that at A. At C the illumination is evidently but little more than half that at A. Points located between the centre and outside would be illuminated to an intermediate degree, but after leaving the outer boundary the illumination would rapidly approach that at the centre of the figure. I am considering always points of least illumination in any region—that is, points situated as far as possible from any lamp. It is evident, therefore, that to obtain a uniform distribution of light, the lamps must be concentrated towards the outer boundary of the space instead of being placed at equal distances throughout, as in the figure.

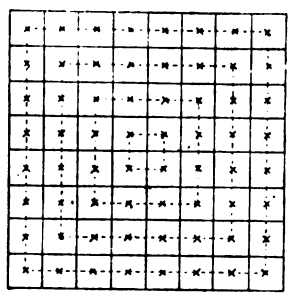

Fig. 2.

But the most interesting question connected with this matter is: what is the effect upon the uniformity of the illumination of grouping the lamps in clusters or using larger lamps at fewer points? It is evident that whatever the candle-power of the lamps or their distances apart in a distribution like that represented in Fig. 1, the relations represented in the table will remain unchanged. It is evident also that the illumination of the central point will be proportional to the intensity of the individual sources (if lamps are placed in clusters, each cluster is to be considered as a source) and inversely to the square of the distance between the sources.

This illumination, is, therefore, given by the formula

$$K \frac{s}{d^2} C,$$

where K is a constant depending on the units employed, s the intensity of the individual sources, d the common distance between them, and C the quantity in Column III. of the table corresponding to the number of sources as found in Column V.

Compare the illumination at the centre of an area lighted by 576 lamps with that at the centre of the same area lighted by the same lamps arranged in 144 clusters of four lamps each. If s and d represent the intensity and distance in the first case, $4s$ and $2d$ will represent the corresponding quantities in the second case. C in the first case is 2·905 corresponding to 576 sources. In the second case, for 144 sources C is 2·363. The relation sought is, therefore,

$$\frac{K \frac{4s}{4d^2} 2{\cdot}363}{K \frac{s}{d^2} 2{\cdot}905} = {\cdot}813$$

The light at the central point with the fewer sources is only 81 per cent. that obtained under the first arrangement. Other points of minimum illumination will suffer in like manner. On the other hand, points near the clusters of lamps will be much more strongly illuminated than corresponding points near the single lamps of the first arrangement.

If it be required that the illumination at no point shall be less in the second case than in the first, it will be necessary to increase the intensity of the sources nearly 25 per cent., or make the cluster consist of five instead of four lamps.

Again, suppose an area lighted by 64 16-c.p. lamps distributed as in Fig. 2. It is required to substitute 16 lamps of larger candle-power distributed as in Fig. 3, and fulfilling the condition that the minimum illumination shall be no less in the latter case. If x be the candle-power of the larger lamps, we have:

$$\frac{x}{4d^2} \times 1{\cdot}511 = \frac{16}{d^2} \times 2{\cdot}046,$$

$$x = 64 \times \frac{2{\cdot}046}{1{\cdot}511} = 86{\cdot}7.$$

From which it appears that the total candle-power must be increased 35½ per cent. If the 16-c.p. lamps consumed 3·5 watts per candle, the larger lamps to compete with them should consume less than 2·6 watts per candle.

It will be noted from the two examples given, that the loss from reducing the number of sources in a given ratio is less when the number is large. In other words, large lamps, or clusters of lamps, can be more economically used for large than for small areas.

An inspection of the table will show, that while a given area may be lighted satisfactorily by 16 clusters of four lamps each, an area one-fourth as large, lighted by four

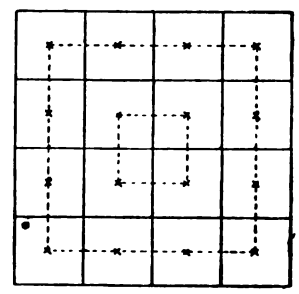

Fig. 3.

clusters at the same distance apart, would not be as well lighted with six lamps to the cluster. It will be seen also that the larger the area, the further apart may lamps of the same candle-power be placed. For example, a room 40ft. square with 16 lamps 10ft. apart, is fully as well lighted as a room 16ft. square with four lamps 8ft. apart.

Let us compare arc and incandescent lights on the same basis, that the minimum illumination shall be the same under both systems. First, I must say that the efficiency of arc lights has been greatly overrated. Instead of being 10 times it is rarely three times, and often only one and a half times that of an incandescent lamp.* This is for the naked arc. For indoor illumination, ground or opal globes are nearly always used, and these cut off fully half the light.† This leaves the efficiency at the most 1·5 times that of the incandescent lamp. The power required for a 16-candle incandescent lamp is 50 watts, and for a full arc lamp 450 watts. The arc lamp must, therefore, replace nine incandescents. Assuming that the lamps are distributed as described in this paper, the table shows that if four arcs take the place of 36 incandescents, their efficiency as compared with the incandescents must be 1·823, and with a relative efficiency of only 1·5, the arc lamps would not light the space as well as the incandescents. If 16 arcs take the place of 144 incandescents, the ratio of the efficiencies required is 1·56, and arcs at 1·5 are still not equal to the incandescents. If 64 arcs take the place of 576 incandescents, the ratio of the efficiencies becomes 1·42, and arcs at 1·5 would be an improvement on the incandescents. It comes then to this, that unless the area to be lighted is so large as to require about 500 incandescent lamps distributed uniformly over it, the use of full

TABLE OF CENTRAL ELECTRIC LIGHT STATIONS.

No.	Town.	Population.	Date of opening.	System of distribution.
1	Aix-la-Chapelle.....	103,500	Jan., 1893	Direct on three-wire system, with batteries.
2	Altona	143,249	Feb., 1892	Ditto ditto.
3	Barmen	125,000	Dec., 1888	Ditto ditto.
4	Bremen	135,000	Aug., 1893	Direct on three-wire system, with sub-battery stations.
5	Breslau	355,186	June, 1891... .	Direct on three-wire system, with batteries.
6	Cassel..	75,000	July, 1891	Two sub-battery stations, the batteries being charged by rectified alternating current.
7	Darmstadt	56,400	Aug., 1888.....	Direct on three-wire system, with accumulators.
8	Dessau	40,000	Oct., 1886	Direct on two- ditto.
9	Düsseldorf.....	155,411	Sept., 1891 ...	Direct on two-wire system to sub-stations, where three-wire distribution commences.
10	Elberfeld	132,000	Nov., 1887.....	Direct on the three-wire system.
11	Gera	40,000	Jan., 1892.....	Ditto ditto with batteries.
12	Greifenhagen	7,000	June, 1892.....	Direct on the two-wire system, ditto.
13	Gummersbach	10,000	April, 1890 ..	Direct on the two-wire system, with battery sub-stations.
14	Hagen(Westphalia)	37,000	Aug., 1890.. ..	Ditto ditto ditto.
15	Hamburg	650,000	Dec., 1888	Ditto ditto, with accumulators.
16	Hanover..... ..	188,000	March, 1891....	Ditto three-wire system, ditto.
17	Cologne	298,732	Oct., 1891	Single-phase alternating, with transformers and no secondary network.
18	Copenhagen	326,000	March, 1892....	Direct on the three-wire system, with batteries.
19	Lübeck	70,000	Nov., 1887.....	Ditto ditto ditto.
20	Mulhouse	76,968	March, 1888....	Ditto ditto ditto.
21	Stettin	120,000	Oct., 1889	Ditto ditto ditto, and a battery sub-station.

arc lamps requiring the same power will leave some parts of the area less brilliantly lighted.

If we could make small arc lamps of the same efficiency as the full arc—by full arc I mean the so-called 2,000-candle lamp consuming about 450 watts—we could improve somewhat upon the result as obtained above. But the fact that the mechanism of a small arc lamp costs just as much as that of a large one, and that each small arc will require as much care and attention as a large one, would place a limit upon the subdivision of the arc even if the efficiency could be maintained. And here I wish to enter a protest against the assumption that I often find in discussions on this subject, that the so-called 1,200-c.p. and 2,000-c.p. arc lamps are 1,200 and 2,000-candle lamps. There is no 450-watt arc lamp in use that will measure 2,000 candles in the direction of greatest intensity, and compared with other artificial sources for general illumination that is measured as other sources are measured, there is no 450-watt lamp that will give, when surrounded by a plain glass globe, 500 candles.

In a linear distribution, as in street-lighting, the arc is at a still greater disadvantage. Remembering that nine 16-candle incandescent lamps can be run with the power required for one 450-watt arc, it is seen that the arcs must be nine times as far apart as incandescents consuming the same power, and to give the same minimum illumination must be 81 times as intense, or about 1,300 c.p. But in no arc lamp as used for street-lighting do the rays proceediug toward the most distant points to be illuminated reach more than one-fourth this intensity. In my way of thinking, the location of arc lamps at intervals of 1,000ft. to 1,600ft., as they are often seen in pretentious country villages and suburban places, is an entire waste of money. A little spot 50ft. to 100ft. in diameter under each lamp is brilliantly lighted, while the more distant points are in darkness all the more profound from the loss of sensitiveness of the eye when in the strong light. Incandescent lamps at intervals of 100ft. to 200ft., which could be run by the same power, would give a far better illumination.

Of course, in deciding between the use of arc and incandescent lamps in any special case, there are other questions to be considered besides that of the power required to operate. Practical questions of installation may outweigh all others. The consideration of these is foreign to this paper. The question I have considered is purely one of efficiency, and in treating that question I have assumed that every part of a space to be lighted needs the same amount of light. I have omitted from the consideration all effects of reflection from ceilings, walls, or reflectors purposely provided, as these are too various, and depend too much upon the conditions in each special case to be introduced into a general discusion. My main object has been to point out to just what extent the general illumination of a space is effected, other things being equal, by the use of large in the place of small sources using in the aggregate the same power, and I trust the figures and illustrations I have given may be found useful in considering the special cases that may arise.

WORKING RESULTS OF SOME CONTINENTAL ELECTRIC LIGHT STATIONS.

A lengthy statistical report concerning the working results of some continental electricity works during the year 1892-93 has been prepared at the request of the Statistical Commission of the Free Union of Representatives of Electricity Works (Freie Vereinigung der Vertreter von Elektricitätswerken). This report, which has been compiled by Dr. O. Gusinde, of Hanover, in conjunction with the editorial staff of the *Elektrotechnische Zeitschrift*, is printed in the latter journal in its issue of May 24. Although the information can hardly be regarded as up to date, yet it is as recent as it is possible to obtain, and a brief summary of the report will doubtless prove interesting.

GENERAL WORKING RESULTS.

No.	Energy produced in hectowatt-hours.			Average demand for power in percentage of the normal output.
	Whole year.	Maximum in 24 hours. (Date.)	Minimum in 24 hours. (Date.)	
1	—	—	—	—
2	2,003,572	22,510 (16/12/92)	692 (7/9/92)	86·5 of the steam-power; 83·4 of the dynamo.

21	3,148,700	22,600 (17/12/92)	1,560 (10/7/92)	68

It is pointed out that many particulars are given in the annual reports of the electricity works, but that very little

Digitized by Google

information is published in them as to the experience gained in working details. This fact led to the bringing together once a year of the engineers of the electricity works, so that a verbal expression of opinion on the subject could be ascertained at the gatherings of the Free Union. The first meeting of the Free Union took place in Berlin in July, 1892, and the second in Dresden in June, 1893, whilst the third will be held in Leipsig on the 5th and 6th inst.

It was decided at the Berlin gathering that an interchange of yearly reports should be carried out, and a commission—consisting of Mr. Döpke, of Cassel; Dr. Gusinde, of Hanover; and Mr. Joly, of Cologne—was appointed to deal with the matter, and to issue a circular asking for answers to various questions. The latest time for sending in replies was August 15, 1893, and to Dr. Gusinde, assisted by the staff mentioned, was allotted the duty of putting the statistics into proper order. The report has now been published. The figures, which only refer to those electricity works associated with the Free Union, are as complete as it was possible to make them. Annexed are some of the most important tabular statements.

THE EFFICIENCY OF ALTERNATING-CURRENT TRANSFORMERS.

THE MORDEY, SCHUCKERT, AND OERLIKON TYPES.

In connection with the late electrical exhibition at Frankfort-on-the-Maine, a committee was appointed under the presidency of Dr. H. F. Weber, of Zürich, on the subject of testing alternate-current transformers, and the official report has now been published.

The following alternate current transformers were given to the committee to test: two Mordey transformers of from 3,000 to 6,000 watts from Messrs. Kremenezky, Mayer, and Co., of Vienna; a 10,000-watt transformer of Messrs. Schuckert and Co., of Nuremberg; and an Oerlikon transformer of 7,500 watts. In order to make the tests as complete as possible, there were measured the primary current strength, the primary pressure, the energy conducted to the primary winding in a unit of time, the resistance of the primary coils, the secondary current strength, the secondary pressure, and by direct measurements the energy leaving the secondary winding in a unit of time, and the resistance of the secondary coils. The measurements of the current strength were made with Thomson balancing instruments and Siemens electrodynamometers; the pressure was measured with Cardew voltmeters; and the primary and secondary energy by means of Ganz wattmeters. The measurements were carried out by Dr. Behn, of Eschenburg, Dr. Kopp, Mr. Nizzola, Dr. Sahulka, Mr. Schmoller, Dr. H. F. Weber, Dr. G. von Wiss, Dr. Dietrich, and Dr. C. L. Weber. Special tests were made as to the accuracy of the measuring instruments.

As the source of current for the tests of the transformers, a Mordey alternating-current machine, supplied by Messrs. Kremenezky, Mayer, and Co., was employed. This machine had a normal output of 25,000 watts, a pressure of 2,000 volts, ran at 850 revolutions per minute, and had a periodicity of 100 per second. Each transformer was tested at different loads in as complete a manner as possible. For the load there was used a system of 300 16-c.p. 100-volt incandescent lamps. The lamps could either be switched in and out in simple parallel in 30 groups of 10, or two in series in 15 groups of 20 lamps each, in the secondary circuit of the transformer.

The speed of the Mordey alternator was kept as far as possible constant during the loads in a series of tests, and the exciting current was so regulated that the secondary tension had almost the same value.

Besides these series of tests each of the four transformers was submitted to a series of experiments, in which there was inserted before the primary winding a resistance, as far as possible free from self-induction, of twice the size of the resistance of the primary winding in order to change and notice the length of the difference of phase of the primary tension and of the primary current strength under small loads.

The two types of Mordey transformers tested were calculated respectively for:

3,000 watts normal output; 2,000 volts primary pressure; 100 volts secondary pressure; number of periods 100.

6,000 watts normal output; 2,000 volts primary pressure; 100 volts secondary pressure; number of periods 100.

These transformers could be tested under their normal conditions, as the alternate-current dynamo feeding the converters served for the production of the primary current.

The Oerlikon transformer was of 7,500 watts output; 2,000 volts primary pressure; 100 volts secondary pressure; number of periods 50. The normal number of periods, however, could not be obtained, as only an alternate-current dynamo with a periodicity of 100 was available.

The Schuckert transformer had a normal output of 10,000 watts, a primary pressure of 2,500 volts, a secondary pressure of 139 volts, and a periodicity of 50.

By applying their normal periodicities as numbers of the change of the primary in relation to the secondary pressure at a constantly maintained secondary in relation to primary pressure between zero and normal load, the values of the four transformers were:

Mordey	3,000-watt	transformer	2·4	Percentages of the outgoing pressure at zero load.
„	6,000 „	„	2·5	
Oerlikon	7,500 „	„	3·0	
Schuckert	10,000 „	„	3·0	

It was found that the loss of energy through heating of the primary and secondary coils at full load was between 2·3 to 2·5 per cent. in the case of the Mordey transformer, 2·36 per cent. with the Schuckert converter, and 1·75 per cent. in the case of the Oerlikon transformer. The amount of loss of energy in the iron was shown by the results to be with both types of Mordey transformers and the Schuckert converter to be independent of the load. The reverse was the case with the Oerlikon transformer, in which the loss of energy in the iron rose with an increasing load in a similar manner to the energy losses in copper.

The efficiency of the small Mordey transformer was found to be 94·5 per cent., and of the large converter 96·3 per cent.; that of the Oerlikon transformer at 100 periods was 94 per cent. at full load, and somewhat less at 50 periods; and of the Schuckert transformer the efficiency was 94 per cent. at full load.

WIRING CONNECTIONS FOR A DOUBLE MOTOR EQUIPMENT.

We give herewith diagrams showing the wiring and connections necessary for a car equipped with two Westinghouse No. 3 motors with type G controllers. Fig. 1 shows

Digitized by Google

the entire wiring diagram for a car so equipped. Fig. 2 is a diagram showing the connections of the controller for both a single and a double motor equipment. Fig. 3 exhibits the arrangements of contacts provided upon the controller cylinder. The diagram on the left of Fig. 3 is for a single equipment, and that on the right for a double motor equipment. The first contact is made at the left in each case, and the movement is then toward the right for the successive points from 1 to 10. Fig. 4 represents in a diagrammatic form the 10 sets of connections produced by the arrangement of connections shown in Fig. 1. The first contact places the motors in series with all the resistance and with each other. In the second, part of the resistance is cut out, and in the third all, leaving only the two motors in series with each other. At the tenth step all resistance is out, and the two motors are connected in multiple. It will be noticed that no attempt is made to cut out a part of the field magnet coils at certain steps in the change from the start to maximum speed. The diagrams are reproduced from the *Street Railway Gazette*.

PRACTICAL NOTES ON DYNAMO CALCULATION.—I.*

BY ALFRED E. WIENER.

The author has endeavoured in the following articles to develop an entirely practical treatise on dynamo calculation, differing from the usual text-book methods, in which the application of the various formulæ requires more or less experience in dynamo design. The present treatment of the subject is based upon results obtained in practice, and therefore, contrary to theoretical methods, gives such practical experience. Information of this kind will, in the following, be presented in the form of original tables and formulæ derived from the data and tests of nearly 200 of the best modern dynamos, of American as well as European make, comprising all the usual types of field magnets and of armatures, and ranging in all existing sizes.

The author's collection of dynamo data, which has been considerably increased by material gathered during his recent World's Fair visit, contains full particulars of the following types of continuous-current machines:

AMERICAN MACHINES.	Sizes.
Edison single-horseshoe type	20
,, iron-clad type	10
,, multipolar central-station type	10
,, bipolar arc light type	6
,, four-polar marine type	4
,, small slow-speed motor type	4
,, railway motor type	3
Thomson-Houston spherical arc light type	9
,, ,, spherical incandescent type	4
,, ,, multipolar type	3
,, ,, railway motor type	2
Brush double-horseshoe ("Victoria") type	16
Sprague double-magnet type	13
Entz multipolar marine type	5
Weston double-horsehoe type	3
Lundell multipolar type.	
Short multipolar railway motor type.	
Crocker-Wheeler bipolar motor type.	

ENGLISH MACHINES.	
Kapp upright horseshoe type	4
Paterson and Cooper "Phœnix" type	2
Mather and Platt "Manchester" type	2
Mather and Platt "Edison-Hopkinson" type	2
Paris and Scott double-horseshoe type	2
Crompton double-horseshoe type.	
Kennedy single-magnet type.	
"Leeds" single-magnet type.	
Immisch double-magnet type.	
"Silvertown" single-horseshoe type.	
Elwell-Parker single-horseshoe type.	
Sayers double-magnet type.	

GERMAN MACHINES.	
Siemens and Halske inner-pole type	3
Schuckert multipolar flat-ring type	3
Gülcher multipolar type	2
Fein inner-pole type.	
Fein iron-clad type.	
Fein inward-pole horseshoe type.	
Lahmeyer iron-clad type.	
Eickemeyer iron-clad type.	
"Allgemeine" inner-pole type.	
Bollmann multipolar disc type.	

FRENCH MACHINES.
Gramme bipolar type.
Marcel Deprez multipolar type.
Desroziers multipolar disc type.
Alsacian Electric Construction Company inner-pole type.

SWISS MACHINES.
Oerlikon multipolar type.
Brown double-magnet type.

In this list are contained the generators used in the central stations of New York, Brooklyn, Boston, Chicago, St. Louis, and San Francisco, United States; of Berlin, Hamburg, Hanover, Dusseldorf, and Darmstadt, Germany; of London, England; of Paris, France; also the General Electric Company's large power generator for the "Magic City" intramural railway plant, and other dynamos of fame.

In the author's possession, but not included in the above list, are, furthermore, particulars of various special designs, and incomplete data of generators and motors, too numerous to be mentioned. Besides these the author has at his command considerable data on alternating-current machines; but since the present treatise is to cover the ground of continuous-current dynamos only, no enumeration of the former has been made here.

The author believes that the abundance of his material entitles him to consider the following treatise, and especially the tables and data contained therein, as universally applicable to the calculation of any dynamo.

I. CALCULATION OF ARMATURE.

1. *Unit Armature Induction.*—It is evident that a certain length of wire moving with the same speed in magnetic fields of equal strengths will invariably generate the same E.M.F., no matter whether the said length of wire be placed on the circumference of a drum or of a ring armature, and no matter whatever may be the shape of the field-magnet frame or the number of poles of the different magnetic fields.

In order to obtain such a constant suitable for practical purposes, we start from the definition: one volt E.M.F. is generated by a conductor of unit length if moving with unit speed and cutting 10^8 C.G.S. lines of force per second.

From this definition, which is given in the absolute (C.G.S.) system of measurement, we can easily calculate a constant for our practical units.

Since the English system of measurement is still the standard in this country, we will take 1ft. as the unit length of wire, and 1ft. per second as its unit linear velocity. For the unit of field strength we take an intensity of 20,000 lines of force per square inch, this being a good average number occurring in practice, as can be seen from the table of practical field densities, which will be given later on.

Based upon these units, and upon the law: "The E.M.F. generated in a conductor is directly proportional to the length and the cutting speed of the conductor, and to the number of lines of force cut per unit of time," the derivation from the definition above referred to has been made in tabular form as follows:

Length of conductor.	Cutting velocity.	Density of field.	E.M.F. generated.
1cm.	1cm. per second.	100,000,000 lines per cm.^{2}	1· volt.
1ft.	,, ,, ,,	,, ,, ,,	30·48 ,, (1)
,,	1ft. ,, ,,	,, ,, ,,	929·03 ,, (2)
,,	,, ,, ,,	20,000 ,, ,,	·186 ,, (3)
,,	,, ,, ,,	,, per square inch	·0288 ,, (4)

(1) 1ft. = 30·48cm. (2) 1ft. per second = 30·48cm. per second; $30{\cdot}48 \times 30{\cdot}48 = 929{\cdot}03$. (3) $\frac{100,000,000}{20,000} = 5,000$; $\frac{929{\cdot}03}{5,000} = {\cdot}186$. (4) 1 square inch = 6·45cm.^{2}; $\frac{{\cdot}186}{6{\cdot}45} = {\cdot}0288$.

The result thus obtained can be worded: "Every foot of conductor moving with the velocity of 1ft. per second in a magnetic field of the density of 20,000 lines of force per square inch generates an E.M.F. of 0·288 volt."

If two or more equal lengths of wire are connected in parallel, in each of these lengths every foot of wire will generate ·0288 volt, but these parallel E.M.F.'s will not add, but the total E.M.F. generated in one length will also be the total E.M.F. output of the combination.

In an ordinary bipolar armature, now, there are generally two such parallel branches, each branch generating the total E.M.F. This necessitates 1ft. of generating wire in each of these two parallel circuits, or altogether 2ft. of wire, under our unit conditions, in order to obtain an E.M.F. output of ·0288 volt; or, in other words, every foot of the total generating wire on a bipolar armature, at a cutting speed of 1ft. per second, in a field of 20,000 lines per square inch, generates ·0144 volt of the output E.M.F.

In multipolar armatures the number of electrically parallel portions of the winding usually is equal to the number of poles, 2 P, the number of pairs of poles being denoted by P. In such armatures it therefore takes 2 P feet of generating conductor to produce ·0288 volt of output, or the share of E.M.F. contributed to the total output by every foot of the generating wire on the entire pole-facing circumference is $\frac{{\cdot}0288}{2\,P}$, or $\frac{{\cdot}0144}{P}$ volt—that is, ·0144 volt per pair of poles.

This theoretical value of the "unit armature induction,"

* From the *Electrical World*.

Digitized by Google

however, has to undergo a slight modification for the practical use, owing to the fact that generally only a portion of the total generating or "active" wire of an armature is "effective." "Active" is all the wire that is placed upon the pole-facing surface of the armature, "effective" only that portion of it which is actually generating E.M.F. at any time—that is, the portion immediately opposite the poles and within the reach of the lines of force at that time.

The percentage of effective polar arc in modern dynamos, according to the number and arrangement of the poles, varies from 50 to 100 per cent., and usually lies between 70 and 80 per cent. The lowest values of the effective arc, 50 to 60 per cent. of the total circumference, are found in the multipolar machines made by Schuckert, with poles parallel to the armature shaft, and having no separate pole shoes; in these the space taken up by the magnet winding prevents the poles from being as close together as in machines of other types. The highest figure, 100 per cent., is met in some of the Allgemeine Elektricitäts Gesellschaft dynamos, in which the poles are united by a common cast-iron ring (Dobrowolski's pole bushing).

For these various percentages I have found the following average values of the unit armature induction per foot of the total active wire:

TABLE II.—Practical Values of Unit Armature Induction.

Percentage of polar arc.	E.M.F. per foot of active armature conductor per pair of poles at unit velocity (1ft. p.s.) and unit field strength (20,000 L. per sq. in.). Bipolar dynamos.	Multipolar dynamos.
1·00	·0144	·0144
·95	·0142	·0135
·90	·014	·013
·85	·0135	·0125
·80	·013	·012
·75	·0125	·0115
·70	·012	·011
·65	·0115	·0105
·60	·011	·010
·55	·0105	·0095
·50	·010	·009

It will be noticed that the values for multipolar machines run somewhat below those for bipolar ones. This means that, at the same rate of polar embrace, a greater percentage of the total active wire is effective in the case of a bipolar machine, which is undoubtedly due to a greater circumferential spread of the lines of force in bipolar fields.

2. *Specific Armature Induction.*—Knowing the values of the induction per foot of active armature wire at the assumed unit conditions, a general expression can now easily be derived for the "specific armature induction" at any given conductor speed and field density. The induction per foot of active conductor in any armature is:

$$V = \frac{v}{P} \times S \times \frac{F}{20{,}000} \quad . \quad . \quad . \quad . \quad (1)$$

where V = specific induction of active armature conductor, in volts per foot;

v = unit armature induction per pair of poles in volts per foot, at S = 1ft. per second, and F = 20,000 lines per square inch, from Table II.;

P = number of pairs of magnet poles;

S = cutting speed, or conductor velocity, in feet per second, from Table III.;

and F = field density, in lines of force per square inch, from Table IV.

In this formula it is supposed that, as is usually the case, the number of electrically parallel circuits in the armature corresponds to the number of magnet poles. If these two numbers, however, are not identical, half the former number is to be substituted for P.

(To be continued.)

Auffay.—This little town in the Seine Inférieure is lighted by electricity. Current is supplied by a Postel-Vinay dynamo, driven by a Hercules turbine.

INSTITUTION OF CIVIL ENGINEERS.

The annual general meeting to consider the report of the outgoing council, with the statement of accounts, and to elect the council and officers for the ensuing session, was held on Tuesday, Mr. Alfred Giles, the president, being in the chair.

The tabular statement of the transfers, elections, deaths, and resignations during the year showed an effective increase of 188 on the previous total of 5,371, or at the rate of 3½ per cent. per annum, while as regards the students the decrease was 28. The gross numbers on the books on March 31 in 1893 and in 1894 were 6,397 and 6,557 respectively.

A review of the work of the past session was next given, from which it appeared that 19 papers had been read and discussed at the ordinary meetings, treating of separate and clearly defined branches of engineering—municipal, hydraulic, mechanical, mining, and electrical—and also referring to naval architecture. For several of the papers detailed premiums had been awarded to Messrs. Clerke, Kreuter, Vernon-Harcourt, Partiot, Greathead, Fox, Parker, Hunt, Redwood, Commans, and Colquhoun. The papers selected for printing without being read had been numerous and varied, and had ranged over the whole field of modern engineering. Mention was made of several representative memoirs in the various branches, not that they merited greater recognition than the others, but that they served to support the quality of catholicity claimed for the institution. Premiums for papers in this category had been awarded to Messrs. Donkin, Lowcock, Marks, Tanabe, Ewart, and Moncrieff.

The second of the "James Forrest" lectures had been delivered by Dr. John Hopkinson, F.R.S., M.I.C.E., his theme being "The Relation of Mathematics to Engineering." This recondite subject has been presented to a large audience, which testified in a marked manner its appreciation of the lecture.

Eleven supplemental meetings for students had been held. For papers read by students at the institution, and before the local associations, the council had made the following awards: the Miller scholarship (tenable for two years) to Mr. L. H. Appleby; and Miller prizes to Messrs. A. R. Gale, W. Beer, W. G. Wales, H. T. White, P. J. Tucker, H. N. Alliott, A. Watson, W. O. Leitch, and T. H. Watt.

The ballot for council resulted in the election of Sir Robert Rawlinson, K.C.B., as president; of Sir B. Baker, K.C.M.G., Mr. J. W. Barry, Mr. W. H. Preece, C.B., and Sir Douglas Fox as vice-presidents; and of Dr. W. Anderson, A. R. Binnie, W. R. Galbraith, J. H. Greathead, Sir Chas. A. Hartley, K.C.M.G., J. C. Hawkshaw, C. Hawksley, Dr. Alex. B. W. Kennedy, Sir Bradford Leslie, K.C.I.E., J. Mansergh, Sir Guildford Molesworth, K.C.I.E., Sir E. J. Reed, K.C.B., W. Shelford, F. W. Webb, and Dr. W. H. White, C.B., as other members of the council.

The session was then adjourned to the second Tuesday in November.

Steam-Engines for Electric Lighting in Germany.—The Statistical Bureau for Prussia have published figures relating to the employment of steam-engines in the production of electricity in the kingdom. There has been a large increase since 1891. At the beginning of that year there were 983 fixed and portable steam-engines of a total of 49,489 h.p. thus employed. At the commencement of 1892 there was an increase to 1,199 engines of 66,803 h.p., and at the commencement of 1893 to 1,407 engines of 76,045 h.p. Of 1,218 engines, which at the beginning of 1893 were solely used for electricity purposes, 1,089 engines of 48,692 h.p. were used for lighting only, and 14 engines of 1,286 h.p. for transmission of power purposes only. There were 94 engines of 15,336 h.p. used both for lighting and power transmission, and 21 engines of 1,214 h.p. for electrolytic, electrotyping, chemical, and other purposes. Rhineland stands at the head of the Prussian provinces, and is followed by the city of Berlin as regards the number of engines, but the latter is first as regards horse-power.

STILL EXPERIMENTAL RUBBISH.

We are afraid that we do not altogether agree with the conclusions of Mr. Bridgman as regards the advisability of local authorities experimenting. At any rate we should have very strictly to define what is meant by experimenting. No one would at this stage of the investigation, for example, urge a local authority to attempt to light the streets and houses by means of static electricity after the manner of Tesla. Scientific opinion is not satisfied that such a course is feasible; but when it comes to the lighting of a town by means of the ordinary dynamo and its accessories, upon that scientific opinion is decided. To attempt the one would be rash experimenting; to attempt the other would savour of wisdom. Mr. Bridgman seems to imply that the wisdom of the local legislature is shown by waiting, purchasing at a fair valuation when private individuals have proved the matter under consideration to be successful. Applied to electric lighting, this means that, in Mr. Bridgman's opinion, it is better to let private individuals exploit for twenty years or so to show that the undertaking has passed the experimental stage, and then the authorities may safely purchase. We suppose the oft-told tale of Hugh Myddleton and the New River was intended to point the moral, that too early taking part in an undertaking might mean failure, while purchase at the proper moment might mean a gigantic success. We object to this principle applied to electric lighting. The success in the future may be out of all proportion to the success of the present. Fortunately for the local bodies, unfortunately, as many think, for the successful companies, the Legislature has enacted that after a certain period there may be a compulsory purchase of the undertaking. It is pretty certain that, in the usual order of things, when the time of permissible compulsory purchase come round, the undertakings, though they may have been successful, may have recouped the outlay spent upon them, will in no way be said to have reached maturity. The end and aim of central-station lighting will be to light all the streets and houses in the district, and till the very last room is lighted it is impossible to say exactly how great the success, or, rather, how large a return may be obtained. It is impossible in the course of a few years to oust all rivals, or, in fact, to make a very great impression on some rivals; hence development, which in one district may be slow, may in another be very rapid. We have for several years contended that electric lighting has passed the experimental stage; that under ordinary conditions it should pay its way within a year or two, and subsequently the balance-sheet will go on getting better. It is for the general welfare of the community that artificial light should be obtained at the lowest possible cost, and it can only be so obtained when the authority is the undertaker. Had the Corporation of London financed Hugh Myddleton, the City would at this moment have possessed an asset said to be worth twenty millions of pounds. Myddleton was ruined, but he could foresee the valuable nature of his work, and had his contemporaries possessed his foresight

Digitized by Google

we may be sure that the New River, instead of being as it is now, would have been a municipal undertaking. We object to a municipal body becoming middlemen. We do not ask them to become grocers, tailors, or tallowchandlers, but we do think that in all matters relating to light and water, among other things, they should provide for the community, and not let their interests merge into the hands of private individuals. The crux of the whole question Mr. Bridgman will say is in emergence from the experimental stage. The time of that emergence is a matter of opinion. We can, if we like, argue even now that the steam-engine is an experimental machine and not a perfect piece of apparatus. There is no denying the fact, but had civilisation waited from the time of its inception till now for the perfect machine and the end of experimenting, we should have a far different state of affairs in the world than at present exists. This indefinite view of what is experimental and what is not, has an evil effect upon electric light undertakings. It is very easy to cry "experimental"—very difficult to counteract that cry. "Let him prove that it will pay," is the usual cry, instead of ascertaining what is wanted, writing a specification, and paying of the work according to specification. From our point of view the objection to waiting local or municipal enterprise is that even when convinced of utility, possibility, desirability, and successfulness, there is always too much procrastination. The work is not always proceeded with on its merits, but is the shuttlecock of party warfare. Let us do our best to dispel all ideas of putting off because "electric lighting is still in the experimental stage." It isn't; and it will prove of advantage to authorities if they take the matter into their own hands, rather than permit private enterprise to create "vested interests." Depend upon it, when the time for compulsory purchase comes round, if the work is fairly successful, there will be a legal way of getting its proper value. What that proper value will be is perhaps as proportionate to its actual cost, as the value of the New River shares is to their par values.

CORRESPONDENCE.

"One man s word is no man's word,
Justice needs that both be heard."

ELECTRIC LOCOMOTIVES IN FRANCE.

SIR,—I noticed in your issue of last week an item to the effect that the Paris, Lyons, and Mediterranean Railway Company are building a considerable number of new locomotives, both steam and electric. The compound steam locomotives on this line have already obtained prominence on account of their excellent design and good working results, and I presume that the new ones are additional engines of the same or improved type. I do not, however, quite understand, with regard to the electric locomotives, how the first of the two types you name can be an "electric locomotive" when the electric motor is installed, as stated, on the rolling-stock. There is all the difference in the world between a locomotive and a motor car, instances of which may be seen respectively on the South London and the Liverpool Overhead lines, and I would be sorry to see the technical journals transgressing in accuracy of language, seeing that it is their duty rather to guide in this respect those of us who are actively engaged in the industry. The second type of electric locomotive which you mention presents features of great interest, and I shall look forward to more details of it in due course. At present I cannot do more than express my surprise and pleasure at finding any railway company who will undertake the construction of no less than 60 electric locomotives of an output equal to at least 400 h.p. apiece. Moreover, the particulars you give would lead me to think that these engines are intended for freight service, and not to work the high-speed passenger trains, as has hitherto been supposed.

Perhaps you will be able in due course to publish more particulars of these locomotives. I am sure that a detailed description thereof would prove of great interest and value.

Yours, etc., LOCO.

May 28, 1894.

A CITIZEN'S OPINION OF ELECTRIC LIGHTING.

A large number of guests assembled on Thursday of last week at a banquet at the Cannon-street Hotel, given by the Commission of Sewers, to meet the Lord Mayor and Sheriffs, and to do honour to the late chairman, Mr. H. H. Bridgman, F.R.I.B.A. The chair was taken by Alderman Bell, F.R.G.S., who was supported on his right by the Lord Mayor, and on his left by Mr. Bridgman. After various toasts had been honoured, the CHAIRMAN proposed the toast of the evening—namely, "The Health of the Past Chairman." He said that it was usual for the colleagues of the chairman on his retirement to present him with some recognition of their appreciation of his year's work, and the honour of making the presentation to Mr. Bridgman that evening had been placed in his hands. A full-sized portrait in oils of Mr. Bridgman, painted by Mr. Manton, was then unveiled, and the Chairman said that on behalf of his colleagues and himself he had very great pleasure in presenting it to Mr. Bridgman, accompanying the gift with a fervent hope that Mr. Bridgman would long be spared to pursue his duties on the Corporation and the Commission of Sewers.

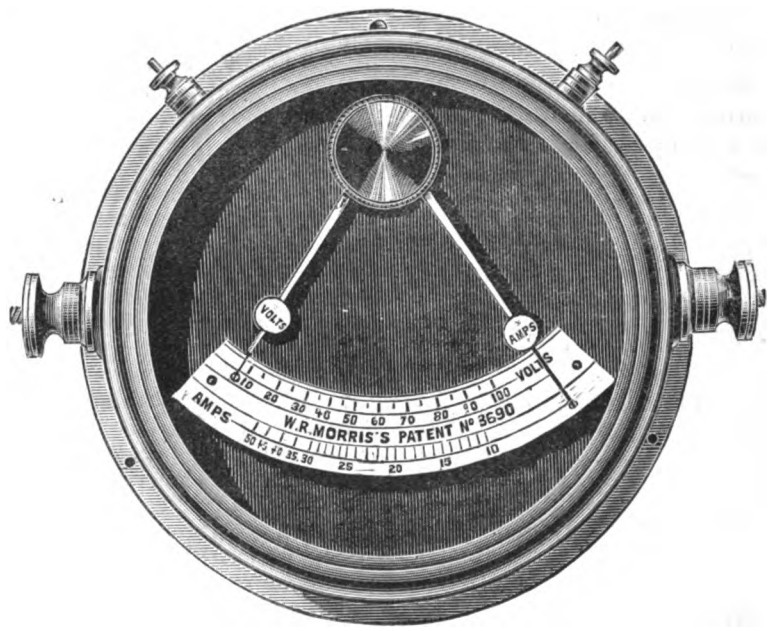
Mr. H. H. BRIDGMAN, in acknowledging the compliment that had been paid him, said: "You have been kind enough, sir, to designate this toast 'the toast of the evening.' I need hardly say how greatly I appreciate the compliment. I thank you much for your kindness in proposing the toast of my health in such unmeasured terms, nor do I fail to appreciate the generous reception which has been given to it by this distinguished assembly. I have for a long time thought it a great pity that so much of the City's past history should lie hidden in obscurity, as it were, for the want of a ready reference enabling one to alight at once upon any and every incident of interest in that history. This it is my intention to supply, and when the facts are briefly annotated in chronological order, innumerable interesting events could, without any trouble, be referred to and enlarged upon, which will, I am sure, awaken a livelier interest than even now exists in the past and present history of the Corporation, and correct any erroneous impression that may exist. As an instance of erroneous impressions, I would mention that I had long entertained the idea that the Corporation's interest in that mine of wealth, the New River enterprise, was lost to the City and Metropolis by some laxity on the part of the Corporation, and many still think so, but I am pleased to find it is not so. My theme to-night, however, if any, should be the Commissioners of Sewers, which had its origin also in the Tudor times, about half a century after the events just referred to. I have nothing to say but in the highest commendation of the manner in which the work is now performed. I do not believe the work could be done better in whosever hands the duties might be placed, and such is the result only of experience. To illustrate this I will only refer to one aspect of the Commissioners' work, and that is the businesslike and sensible manner in which the electric lighting of the City has been dealt with. The City has been rebuked for not undertaking the task of providing its own complete installation and plant for public and private lighting—so much so that a newspaper stated very recently that whereas the cost of the public lamps in St. Pancras—my own parish—where the lighting has been done by the

Digitized by Google

Vestry, is £17 per lamp, yet in the City, where it has been done by a company, it is £27 per lamp, and that St. Pancras had solved the problem of the cost of public lighting by electricity. What are the facts? I showed conclusively, in answer to that statement, that the lighting in the City costs 31 per cent. per lamp less than St. Pancras, all things considered, even supposing the £17 per lamp to be correct; but that even is not so. Prof. Robinson, who has charge of the St. Pancras lighting, has stated in public that the cost per lamp was £23 for only a part of last year. That means that the lighting of the public lamps in St. Pancras is more than 60 per cent. at least beyond the cost of the City lamps. This fact, I think, speaks volumes for the sagacity and foresight exercised by the Commission, who, I am proud to say, have acted on the principle that it would be wrong, at the present time at least, to expend a million of the ratepayers' money in experimental enterprises; but that such undertakings, speculative and hazardous as they must be, are better left to those who might do what they choose with their own money. The City and other authorities as well have the right by Act of Parliament at the proper time to buy such undertakings at a fair and reasonable price, if they think it desirable.

A COMBINED AMMETER AND VOLTMETER.

The instrument illustrated herewith consists of a strong brass case, 8in. in diameter, provided with four terminals.



The two small terminals are used for the volts and the two large terminals for the amperes. The instrument has two pointers; on one pointer is arranged a disc with the word "volts," and on the other a disc with "amperes" on it. By this plan no mistake in the readings can occur. It will be noticed in the illustration that the disc on one pointer is higher than that on the other. This arrangement allows both discs always to be seen, as one disc cannot come in front of the other and eclipse it. Another feature of the instrument is the double scale. The top part is used for the volts, reading from left to right, and the bottom part is utilised for the amperes, reading from right to left. It is not very easy to look at two instruments at the same time, even though they may be placed side by side, but in this instrument what is going on can be seen at a glance, and by multiplying the reading of one pointer by that of the other, the number of watts being used is at once obtained. This makes the instrument, as it were, also a wattmeter, as each pointer is separate and distinct. It can be used separately as a voltmeter or as an ammeter, as the volt and ampere circuits are entirely insulated from one another. No pointed dials are used, each scale being marked by hand during calibration and afterwards engraved. This method is claimed to prevent any errors caused by the use of printed scales or dials.

The principle of the instrument is the action of a solenoid on a suitably suspended piece of iron wire (which weighs only a few grains), and as there are no permanent or electro magnets or springs used, the instruments, as stated, never require recalibrating. The instrument is a gravity one and direct reading, and can always be left in the circuit. To use the instrument it is screwed up vertically, so that the hands point to zero. The two small terminals are connected across the mains, and the two large terminals are connected in the circuit; the current and the E.M.F. will then be indicated at the same time. This instrument has been devised by Mr. W. R. Morris, of 34, Livery-street, Birmingham.

ELECTRIC POWER IN IRON AND STEEL INDUSTRIES.

In our issue of the 11th May was given an abstract of the paper presented to the Iron and Steel Institute by Mr. D. Selby Bigge, on "Electricity as a Motive Power in the Iron and Steel Industries." The same gentleman recently read before the Cleveland Institution of Engineers a paper on "Electric Power in Iron, Steel, and Engineering Works," and before the discussion commenced at a meeting of the institution on May 21, the author supplemented his paper by a few remarks. He stated that since his paper was read he had had opportunities for investigating more closely the possible applications of electric power in iron, steel, and engineering works generally. There was, he thought, no difficulty in applying electric driving to the whole of the auxiliary machinery usually found in these works, but the lines on which the electric power station should be laid down and the methods to employ for the distribution of the electric energy required most careful consideration. In his paper he had laid great stress on short-distance transmission and concentration of power. He then explained certain diagrams showing the method of working in an establishment where the machinery was worked by steam, and the same establishment with electric power introduced. In the first boilers and engines were scattered all over the works, but in the second the power was concentrated, and could be distributed with the greatest ease and with little loss throughout the manufactory. The coal consumed in connection with the electric power was but a small portion of what had been expended in the old works, and where they had available—as at the Cleveland furnaces—waste gases as fuel, the cost was small indeed. The speaker then

Digitized by Google

drew attention to a diagram showing the load line of a motor when running a shop in which a large number of small lathes, drilling and milling machines were at work, and it was curious to note that more power was absorbed when the whole place was running light than when the normal work was going on. This would appear paradoxical at first sight, but it must be remembered that during normal working a large number of the machines were being stopped and started very frequently. This experiment was repeated in different shops of a similar character and with different motors, and always with like results. In referring to the application of electricity to rolling mills, he had stated in his paper read before the Iron and Steel Institute that he did not refer to the heavier class of rolling mills which absorbed several thousand tons of horse-power, but he firmly believed that as regarded the lighter class of mills there was a future for the application of electric power, the great advantages to be derived being the large economy which could be effected in coal consumption and wages. He would like to cancel that statement as to not referring to the heavier class of rolling mills. He had since discussed that question with several engineers conversant with rolling-mill practice, and he had now come to the conclusion that rolling mills could and would be operated electrically, as there were several very great advantages to be derived from such a course. Taking the case of large rolls revolving at, say, 50 or 60 revolutions per minute, the application of the motor might be made through large worm gear. In smaller mills—*i.e.*, where lighter material was being rolled—the motor might be applied direct with a flexible coupling to the rolls. The greatest difficulty in the application of electricity to rolling mills would, the speaker thought, be found in the switching and reversing gear. The motors also would have to be constructed and wound to meet the large rushes of current which would take place, and the collecting brushes would have to be of special design. At Messrs. Dorman, Long, and Co.'s works, Middlesbrough, where electric motors had been applied, there had been a saving of 30 tons of coal per week, as compared with the same machines when steam driven. Taking the National Arms Factory at Liège, where was one of the finest examples of the application of electric power, they had produced rifles at the rate of 1½ h.p. per rifle, whereas at works run by steam in the ordinary way it took 3¼ h.p. to 3½ h.p. There were there 1,500 to 1,800 machine tools at work. At another factory which adopted electricity in place of steam, five or six steam-engines and four boilers were replaced by one engine and one boiler, and the dynamo. The coal consumption before and after its adoption was taken, and it was found that what formerly required an expenditure of three tons daily now needed only one ton. About that ratio had been reported in other cases. As to the efficiency which had been obtained at the National Arms Factory at Liège it amounted to 71·3 per cent. of the indicated horse-power of the engines in useful work. In another works it was 75·5 per cent., and in another 68·5. There was another point in laying down new works or extending old ones engineers would have to consider—the embodying of the electric motor in the actual machine tool, and not to apply it to the shafting.

"UNKNOWN" CAUSES OF FIRE.

BY H. C. CUSHING, JUN.

Every fire which takes place in any city of considerable size is recorded as to location, loss, amount of insurance carried, and the cause, or supposed cause, of the fire. In the city of Boston there were, during the year 1893, 1,233 fires, with a loss of 5,024,765·04dol. Twenty per cent. of all these fires are from unknown causes. When these unknown causes cost property owners more than 1,004,955dol. it is about time that some investigations were made beyond attributing these causes to spontaneous combustion, incandescent or arc light wires, or to any other wires which enter a building. When an inspector cannot satisfy himself that it was from the stoves, careless use of kerosene or matches, it is a very easy thing to lay it to spontaneous combustion or the unfortunate electric light wires.

The person attributing fires to the electric light wires being crossed with some trolley or other high-potential wire outside is probably not aware that every wire entering a building is thoroughly protected at its entrance by a fusible metal which will blow out at any overcharge, thus deadening every wire in the building; and, moreover, there would have to be a decided ground within the building, which is nowadays a very rare occurrence, as the writer's investigations have proved that out of 25 prominent buildings in the city of Boston the insulation resistance to ground proved to average over 2,000,000 ohms. But when I say that the electric light and power wiring should not receive the blame as often as it does, I do not mean to take the responsibility off electricity, for it is through this agent that I have reason to suspect the origin of many of the "unknown" causes, so-called, on fire reports.

When electricity is allowed to roam at large and in vast quantities all along our water and gas pipes and through the ground upon which the city is built, in order to get back to the sources at which it was generated, which are the street railway power stations, it is this state of affairs which is creating a trouble, the extent and seriousness of which is only known to those few who have made it a study. These street railway power stations, operating the overhead trolley system, are constantly generating thousands of electrical horse-power, sending it out by overhead trolley and feed wires to the cars which it operates, and returning it to the station by means of the water and gas pipes which lie in its course. For this reason there is a tremendous electrolytic action going on all the time. The writer has samples of gas and water pipe completely eaten through by electrolytic action in three months after having been placed in the ground near street railway returns.

Whenever this returning current flows in any quantity along a pipe there is bound to be a large fall of potential, varying in different pipes as their carrying capacity increases or diminishes. In the cellars and basements of many houses I have found quite a large difference of electrical pressure between two pipes entering within 1ft. of each other, and, in one instance, it was a very easy matter to take a piece of hoop iron and draw an electric arc sufficient to ignite a piece of waste held near it; and by connecting these pipes together with a piece of No. 18 copper wire, the current flowing through it was sufficient to heat it so that it was impossible to lay one's hand upon it. In the basement of another building within the city limits, I find a man using 25 amperes at eight volts pressure, or electricity enough to run small motors and incandescent lamps, as well as all the electrical bells in the entire building, by simply twisting his wires around two different water-pipes which enter the building. Some time ago my attention was called to two pipes which were so close together that the vibration of an elevator engine caused them to knock together just sufficient to create an arc every time a contact was made and broken. This had been going on so that it had almost completely eaten through the gas-pipe, and it is perfectly evident what would have taken place had this been allowed to go on unobserved. The gas would have been ignited by the electric spark as soon as the first small hole appeared, and disastrous results would have undoubtedly followed.

This difference of electrical pressure between water and gas pipes is now so well known that in a number of cases in the cities of Boston and Cambridge the ordinary electric bell battery is entirely discarded, and the wires from the bells connected directly to water-pipes, the latter furnishing an inexhaustible supply of electricity at the proper pressure to run any number of bells or gas-lighting apparatus, and also to do any quantity of mischief. I can see no reason why fires should not be attributed to this cause, when it can be proved that such a difference of electrical pressure really does exist between any two pipes entering a building in the vicinity of the trolley system of street railways.

There is only one way of eliminating this rapidly increasing danger, and that is by compelling the electric street

Digitized by Google

railway companies to insulate from the ground their entire electrical circuit, and just as soon as a suit for damages is brought by the water and gas companies for systems of pipes destroyed by electrolysis, the railway companies will begin to remedy the evil, which they are more fully aware of than anyone else.—*Electrical Engineer* (New York).

ELECTRIC LIGHT PROJECTORS.

There is no doubt that the use of electric light projectors is progressing. The total number now in use is many thousands, and an approximate idea can be obtained from the fact that since 1877 there have been sold 2,800 Mangin projectors and 300 parabolic projectors. They are efficaciously utilised in the defence of coasts and passes, as well as for port services. Navies have bought a large proportion in connection with the protection of cruisers for the night attacks of torpedo-boats. The first apparatus employed for electric projectors consisted of parabolic mirrors of polished and silvered metal, but under the influence of damp air, salt water, and so on, the polished surface rapidly deteriorated. Fresnel therefore substituted lenses consisting of glass rings, so combined and arranged as to produce good results, but the apparatus was very dear and required delicate handling, especially when the dimensions were at all large. Since then progress in the glass industry has enabled us to obtain glass mirrors of large surface. Such have been manufactured in Germany and by Messrs. Bréguet in France, and are generally obtained by bulging a sheet of glass. These parabolic mirrors are employed concurrently with spherical mirrors made by Messrs. Sautter-Harlé from an idea of Colonel Mangin. This mirror consists of a cap of glass cut on its two faces according to two spheres of unequal radius, and silvered on its concave face. Both forms of projector have advantages and disadvantages. The Mangin spherical mirror has not the geometrical form to assure the parallelism of the rays. Only parabolic form allows of this condition being realised, and a perfect parabolic mirror of exact mathematical curvature would evidently be superior to any other, especially if the source of illumination were reduced to very small dimensions—theoretically to a point. This condition not being realised in practice, the parabolic mirror consequently loses a part of its advantages.

It is also stated that up to the present the parabolic curvature has not been obtainable with the same precision which can be arrived at in spherical mirrors. Taking the Mangin mirror to have an efficiency of 7 to 8 per cent. less than that of a theoretically perfect parabolic mirror, this disadvantage is mostly compensated for by a diminution in the errors in construction, so that the two may be considered equal as regards lighting power. It is possible with spherical mirrors to employ less intense illumination, thereby effecting an economy in electrical energy. As regards weight, the spherical mirrors are by far the heavier. They are consequently best suited for resistance to shocks and vibration, and for use in lighthouses, for the defence of coasts, passes, ports, and for large vessels, while the lighter parabolic projectors are of more service for moving defence, for packet-boats, where a reduction in dead-weight is desired, and for army use during a campaign.—*Revue Scientifique.*

Alternating-Current Motors.—In a recent issue of the *Annales des Mines* M. Walckenaer deals with the question of the employment of alternating-current motors. The author examines successively the principles upon which the various types of this form of motor are based, and then describes a recent application of a distribution of electrical energy by two-phase currents in the Decize mines, carried out by the Creusot Works. This installation comprises a transmission of electrical energy over distances ranging from one to about three miles, and the current is used for operating hauling machinery, ventilators, and for lighting purposes.

A NEW SIMPLIFIED METHOD FOR CALCULATING POLYPHASE ALTERNATING CURRENTS.

In a recent issue of the *Comptes Rendus*, M. A. Blondel describes a simplified method for calculating polyphase alternating currents. An abstract of the article is given in the *Journal* of the Institution of Electrical Engineers.

The author's object is to render the calculations of polyphase currents as simple as those of monophase currents.

The method starts with the two following hypotheses:

1. That alternating currents all vary according to some harmonic law.

2. That the rotating magnetic field produced by a system of harmonic polyphase currents, symmetrical both in intensity and phase, as, in virtue of the good design and secondary reactions of the machine, an intensity and an angular velocity sufficiently constant that the flux cut by any one of the polyphase windings should vary also according to some harmonic law.

From these hypotheses the two following statements may be made:

1. A rotating magnetic field may be represented by a vector, representing the direction in which the induction is a maximum at any given moment, and also the constant value of this maximum.

2. The polyphase currents producing it may also be collectively represented by a single vector, standing for the intensity of an equivalent rotating current passing round the whole circuit; in the same manner the whole of the alternating E.M.F.'s may be representing by a single rotating E.M.F., or vectorial. If q be the number of polyphase currents employed, I_0 their maximum amplitude, U_0 their maximum tension measured between each conductor and the return conductor, then the vectorial intensity, I, and the vectorial tension, U, may be defined as by formulæ (1) and (2):

$$I = I_0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$U = \frac{q}{2} U_0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

The value, ϕ, of a field may always be expressed in terms of the vectorial intensity, I, of the system producing it, and so also the vectorial E.M.F., E, as a function of a field, F, which is producing it, by means of the two expressions:

$$\phi = \frac{\pi}{R} I K \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$E = \frac{k}{4} \frac{2\pi}{T} N F \quad . \quad . \quad . \quad . \quad . \quad (4)$$

where R is a magnetic resistance, K and k two coefficients depending on the type of winding.

By comparing the two formulæ (3) and (4) one obtains the theoretical expressions for the coefficient of mutual induction, M, of two polyphase systems, and of the self-induction, A:

$$M = K k \frac{4\pi}{R} \frac{N_1}{2} \frac{N_2}{2} \quad . \quad . \quad . \quad . \quad (5)$$

$$A = K k \frac{4\pi}{R} \left(\frac{N_1}{2}\right)^2.$$

The above simple definitions will allow of the application of all the ordinary laws and graphical methods used in the case of monophase alternating currents to vectorial currents.

UTILISATION OF REFUSE IN CHELSEA.

The following is the report presented to the Vestry of Chelsea by their surveyor, Mr. T. W. E. Higgens, on the dust destructor at Kensal Town.

In accordance with the Vestry's resolution on March 20, I have been in communication with several firms as to the erection of a dust destructor at Kensal Town. In my report of that date I said "in or near" Kensal Town; but the resolution which was passed on April 3, asking the Baths Commissioners to give the use of their land for dusting purposes, seems to me clearly to indicate that the

Digitized by Google

Vestry intend a portion of the Baths Commissioners site to be used for this purpose. Schemes have been submitted by (1) Messrs. Horsfall, (2) the Municipal Appliances Company, (3) Messrs. Manlove, Alliott, and Co., (4) Livet's British Steam Generator Company.

Messrs. Horsfall's Scheme.—It is proposed to erect three hand-fired cells, to fix a boiler 12ft. long and 7ft. in diameter, with a chimney 60ft. in height. Two estimates are submitted: the first, for iron buildings, and without a roof over the tipping floor, amounts to £1,873; while the second estimate, for substantial brick buildings and roof over furnaces and tipping floor, amounts to £2,273. But in both these estimates foundations to a depth of only 18in. below the ground are provided for, and no provision is made for the paving on the tipping floor or in front of the furnaces. Messrs. Horsfall, whose destructor at Oldham has been examined by the Dust Disposal Committee, intend to use a forced draught, but state that by introducing it at the back of the furnace, they will be enabled to put a stop to the noise caused by the steam jet. The opinion that the noise caused by the forced draught might be minimised by proper arrangement of the inlet, was lately expressed by Mr. Crompton in a paper read before the Society of Electrical Engineers. The three cells will burn 22½ tons per day, and the makers will guarantee 45 i.h.p. all the time the cells are in full work, reckoning 20lb. steam per indicated horse-power per hour at 80lb. pressure equals 90 gallons water evaporated per hour. If three hand-fired cells are used, one man to each shift of, say, eight hours will be required.

The Municipal Appliances Company's Scheme.—In this scheme four cells are provided with chimney 150ft. high, and two steam generators of about 70 h.p. collective when three furnaces are in use; the furnaces are sunk so that a clinker lift and two silent blowers will also be provided for the furnaces. Brick walls will be built to the sheds, and they will be roofed with galvanised iron roofing. The roadway is to be paved with 4in. granite cubes, and blue brick paving is to be laid in other places where necessary. Boundary walls on the canal bank and at the east end are also estimated for. The total estimate amounts to £4,086. This firm, however, have on a former occasion submitted a scheme to the Bath Commissioners, and they state they are prepared to modify that scheme, and construct four furnaces and three boilers with all necessary works, except boundary walls, for £4,812, but if the furnaces were sunk to a depth of 4ft. the cost would be £4,895. If in the latter scheme four Thwaite boilers, giving 30 h.p. each, were used the total cost would be £4,975.

Messrs. Manlove and Alliott's Scheme.—A two-cell destructor to be built of the kind known as Fryer's improved patent, with chimney 120ft. high. One double fume cremator (Jones's patent) and also forced air blast to be provided, also one multitubular steam-boiler 11ft. long and 6ft. in diameter, and auxiliary furnace for coal firing. An elevator will be used for raising the refuse to the top of the destructor, and a 4-h.p. vertical engine will be fixed for working it. The sides and roof of the buildings will be of corrugated iron. The estimate is £2,937, but this does not include the foundations. If a wrought-iron chimney, lined with firebrick, mounted on brick base, were substituted for the brick chimney, the cost would be £2,437, without foundations.

The British Steam Generator Company's (Livet's) Scheme.—Mr. Cheesewright, their engineer, writes: "If 84 tons of dust-bin or trade refuse be screened, an installation precisely similar to the one at Halifax would be ample for the work you want it to do, and would generate steam sufficient to give 120 i.h.p. for 144 working hours. The approximate cost of the Livet's generator, brickwork and furnace complete, would be £1,200—this is exclusive of chimney and other buildings. A royalty for the use of the patents of, say, 9d. for each and every ton of refuse or rubbish destroyed will be charged, this royalty to be payable quarterly for 12 years from the date of the installation. This arrangement is thought to be the best for the taxpayers, as the charge is borne by the existing ratepayers, although it is advanced in favour of the use of the Livet system that it must be a source of great profit to any vestry or corporation."

The estimates therefore are: (1) Horsfall, £2,273; (2) Municipal Appliances Company, £4,086; (2A) ditto baths scheme, £4,895; (3) Manlove and Alliott, £2,937; (4) Livet, £1,200.

Scheme No. 1.—In this form, however, the estimates cannot be compared, as they are not all for the same work. In No. 1, for instance, the foundations are only taken as 18in. deep, and no paving is provided for. The paving would cost about £350, extra foundations £100, foundations for chimney £100, making a total of £2,283 for three cells and a chimney 60ft. in height.

Scheme No. 2.—In No. 2 the cost will be £4,086 for four cells, a chimney 150ft. high, and boundary walls. This looks considerably more expensive than No. 1, but when allowance is made for the extra cell, the boundary walls and the extra height of the chimney, the estimate is not greatly in excess of No. 1.

Scheme No. 2A.—In No. 2A, a scheme suitable for adoption by the Vestry in conjunction with the Baths Commissioners, the cost will be £4,895 for four cells (half sunk) and a chimney 150ft. high.

Scheme No. 3.—In No. 3 the cost will be £2,937 for two cells and chimney 120ft. high, but with paving £350, and foundations £100, the chimney foundations £100. the cost would be £3,487, and if another cell were added at a cost of £500, the total will be £3,987.

Scheme No. 4.—As regards No. 4, the Livet system, I do not think that the scheme proposed can meet with the approval of the Vestry. In the first place, it is proposed to screen the refuse, and secondly, the suggestion is made that the Vestry should pay a royalty of 9d. per ton for 12 years. Under certain conditions screening the refuse may be desirable, but the annual payment of a royalty is most undesirable. After all the statements made as to this system, I can only describe their offer as most disappointing.

Cost of Schemes.—It will thus be seen that the costs will be: No. 1. £2,823 for three cells, 60ft. chimney. No. 2. £4,086 for four cells, 150ft. chimney and boundary walls. No. 2A. £4,895 for four cells, 150ft. chimney, to be adapted to heat baths. No. 3. £3,987 for three cells, 120ft. chimney, and cremators.

Cost, Working and Maintenance.—The cost of working and maintenance is, of course, an important matter. We would probably require three shifts of eight hours and one man for the yard during the day, which would amount to £6 per week, or £312 per year. The cost of removal of clinkers, etc., allowing a residue of 33 per cent., say, one-third on 5,000 tons per year = 1,666 tons barged away at, say, 2s. 8d. per ton, will be £222 per year. If the cost of a four-cell destructor and chimney, 150ft. high, is estimated at £4,000, the interest on the capital at 3½ per cent. would amount to £140 per annum, and if repairs, depreciation, rates, taxes, and gas are estimated at only 10 per cent., they would amount to £400. The annual cost therefore would be: labour, £312; clinker removal, £222; interest and repayment of capital, £281; repairs, depreciation, rates, etc., £400; total, £1,215.

The present price of barging away 5,000 tons amounts to £791. It is therefore apparent that to erect a destructor without utilising the heat would mean an extra expense.

The question of the purpose to which the heat obtained could be put and the saving caused thereby must now be considered. Two purposes have been suggested—first, baths; secondly, electric lighting.

If 5,000 tons are collected during the year, it means about 13¾ tons per day for everyone of the 365 days in the year, and every ton will evaporate not less than 40lb. of water per hour for 24 hours; thus every ton of refuse will give 2 h.p. for 24 hours. I have no knowledge as to what amount of steam may be required at the Kensal Town Baths (if baths are built), but according to Messrs. Horsfall's guarantee, 1lb. of water is evaporated, from 60deg. F. to steam at 80lb. pressure per square inch, by 2½lb. of refuse, in addition to the steam used for steam jets, boiler feed, pumps, etc. (Note.—1lb. of good coal will evaporate 10lb. of water.)

As regards utilising the heat for electric lighting, there are many considerations to be borne in mind. In Kensal Town there are slightly over 200 lamps scattered over

Digitized by Google

seven miles of streets. To lay down cables in seven miles of streets for street-lighting only (supposing that there was sufficient power in the destructor to light the lamps) would be an exceedingly costly proceeding, and the amount of energy wasted in overcoming the resistance of the conductors alone would be enormous, especially when it is taken into consideration that the amount of electricity required for the 200 lamps (16 c.p.) at 100 volts would only be about 100 amperes. In fact, to think of lighting the street lamps in the whole of the district from the heat generated in the destructor under present conditions is quite out of the question, apart from the legal objections. It therefore remains to be seen what portion of the district, if any, could be lighted, provided that the heat is not required for the baths.

Before the Vestry could break up the streets to lay mains for electric lighting it would be necessary to obtain a provisional order from the Board of Trade, and if an order were applied for the Vestry would be required to supply electricity to private houses within a certain area, and a constant supply within that area would have to be maintained under somewhat stringent provisions. Although the demand for private lighting in this neighbourhood would probably be very small, yet the obligation to provide a constant supply of electricity at a constant pressure, with the limited power which would be available if such a small destructor were the only source of power, is one of such a serious nature that it would not in my opinion be wise for the Vestry to undertake it.

If the average horse-power available is only about 26 for 24 hours, there are, of course, many days when less would be available. Suppose that 20 h.p. were only available for 24 hours, and that half the time batteries were being charged. Then we would lose 7 per cent. in the dynamos, and 20 to 25 per cent. in the batteries, or a loss of nearly 5 h.p., without taking into consideration the losses in mains. But as 15 h.p. will only light about 150 c.p. incandescent lamps, it seems hardly worth the trouble and expense obtaining a provisional order to do this, especially as the destructor buildings and vestry offices would require almost half this number.

As statements have lately been circulated to the effect that London could be "lit with electric light for nothing," and as the idea is prevalent that any town can be lighted by its dustbin refuse, it may be as well here to mention that in a paper read before the Society of Arts last February Prof. Robinson stated the cost of a unit sold, with repayment of capital and maintenance, amounted at St. Pancras to 5·18d., and that the cost of coal per unit sold amounted to 1·21d., and this price he thought was excessive. The saving by using dust will not be the 3·97d. per unit, which is the difference between the cost of coal and the total cost of a unit. For if we take Messrs. Horsfall's guarantee that one ton of refuse will give 1 h.p. for 48 hours, and suppose that we will have no losses of any sort (an ideal state of things), the ton of refuse will give us about 35 units, so that 64lb. of refuse will give us one unit, or will be equivalent to 8lb. of coal. The cost of coal will be ·760d., while the cost of barging away the 64lb. of refuse would be 1·086d., making a total of 1·846d. But this is not all gain, because 21lb. of the refuse would have to be removed as clinker, and would cost about ·317d., so that the apparent gain would only be 1·529d. per unit. And if the cost per unit sold is 5·18d., there is a difference of 3·651d. per unit. Thus in this case electricity "for nothing" means at a cost of more than 3½d. per unit, even in such an ideal state of things as I have supposed, where I have taken the cost of coal at per unit sold, and the refuse efficiency per unit generated, whereas between the two there is a great gulf in the shape of losses in dynamos, in batteries, and in mains, which would sink any company that were to calculate their price for electricity without taking it into consideration. It is also certain that the cost of working and maintenance of the destructor plant would be in excess of that of the ordinary engines. I am, therefore, of opinion that the cry of "London lit for nothing" is a trifle delusive at the present time, for if the Livet furnace will increase the evaporative power of house refuse, I can see no reason why it should not increase the evaporative power of good coal in like proportion, and enable electricians to realise their ideal of 2½lb. of coal per unit generated.

So far as the schemes now before the Vestry are concerned, if it is thought advisable to erect a destructor on sanitary grounds, and to utilise the heat for the baths—and this seems to me to be the best means of utilising it—I would suggest that scheme No. 2A, that of the Municipal Appliances Company, be adopted, as this scheme has been worked out for the Baths Commissioners, and is, therefore, I presume, suitable for their purposes, but no doubt some arrangement would have to be made to provide a supply of very inferior coal to be used when sufficient dust was not available. The scheme would cost £4,895, but as this is more costly than one suitable for the Vestry's requirements, the whole cost ought not to fall upon the Vestry, unless the extra cost be taken as an equivalent to the site which is handed over.

If, however, the Vestry desire to erect a destructor, and utilise the heat for lighting the offices and destructor buildings, and any lamps around the premises which might be lighted without a provisional order, I would suggest scheme No. 1, with the addition of a chimney 120ft. high.

Before deciding upon the actual scheme, however, the Vestry should decide whether the time has yet come when a dust destructor at Kensal Town will be advantageous. The present cost of barging dust will amount to about £800 per annum.

Since writing the above report, I have received from the Municipal Appliances Company a plan showing the application of the "Thwaite" boilers to their refuse furnace. The letter states that each furnace complete with a steam generator would cost £500, provided that at least three were ordered. The special feature in these boilers is that they are fixed on top of the destructor, and no doubt are the very best type to generate heat, though whether they are the best type to destroy foul gases is not so obvious, for at Birmingham boilers form the top of the furnace, but while giving excellent results as to evaporation of water, Prof. Forbes says of them: "It was necessary there to keep up steam for the treatment of the excreta, and steam was got up from these furnaces by putting the boilers directly over the furnace. In consequence of this, the combustion is very imperfect. The large cooling surface of the boilers impedes the combustion in an effectual degree." I cannot, of course, say that the same result will happen with these boilers, but I think that the tendency in some quarters is to sacrifice efficiency in cremation of gases to record breaking in steam production, and this in a destructor which has been called into existence primarily to cremate is a mistake.

THE COST OF ELECTRICAL ENERGY.

We give below Mr. Crompton's reply to the discussion on his paper, before the Institution of Electrical Engineers, on the "Cost of Electrical Energy."

Mr. R. E. Crompton said: I shall be obliged to reply very briefly, but hope to be allowed to answer the respective speakers more fully in the *Proceedings*. I have first to thank Mr. Raworth for his very cordial appreciation of my paper. I assure him that I had not the gentlemen named by him in my mind when writing the paper, but rather the gentlemen who are always advocating the Lancashire boiler and the long-stroke horizontal type of mill engine as the perfect type of plant for us electrical engineers to adopt for our supply stations. As Mr. Raworth was the first to take up my point on the use of Lancashire boilers, and so many others have spoken on this subject, I must point out that in my paper I have admitted that these boilers even without economisers do give excellent results on test trials, but the accounts I am dealing with show that the Lancashire boilers in actual use for electric lighting purposes have yielded a high evaporative efficiency. I believe the cause of this to be that these boilers fall off rapidly in efficiency when the firing rate is raised above 20lb. of coal per square foot of grate surface, and under the condition of electric lighting supply such a rate of firing must often be exceeded for the periods of maximum load. My figures show that the same difficulties do not exist with the multitubular boilers, either with the locomotive, marine, semi-marine, or the Babcock and Wilcox type.

Mr. Halpin asked me whether the forced rate of firing which I mentioned in relation to Babcock and Wilcox boilers was not, after all, a very low rate. I think I can satisfy him in this when I say

* *Electrical Engineer*, vol. x., p. 435.

Digitized by Google

that the boilers I had in my mind occupy a space of about 16ft. long by 12ft. high by 9ft. wide, and at this forced rate they evaporate water enough to supply 600 h.p. indicated in the Willans engines. I do not know another boiler occupying this space which can stand this rate of firing and yet work with fair economy.

Time prevents me from replying at length to General Webber's remarks. I may say at once that most of his remarks and the arguments on them are based on erroneous information. I can, however, point out this evening that he has accused me of under-estimating the capital cost of my ideal station, whereas in his own paper describing the works of the City of London Company he estimates the capital cost of the works will be £75 per kilowatt. Mr. Geipel, later in the evening, named an even lower figure, whereas I have allowed in the present instance the very liberal figure of £100 per kilowatt of maximum load. This is a specimen of the careless way in which General Webber has read my paper.

With regard to his personal remarks, I do not think it dignified for me to make a reply to them.

Mr. Robinson and others who have spoken this evening, have stated that my ideal figures of works economy are pitched too high. I may possibly be wrong in this respect. I wished them to be difficult of attainment, and therefore pitched them high.

For Mr. de Segundo's information, I may point out that Prof. Kennedy has stated this evening that 4½lb. per unit sold to the customers is actually reached every day in some of our best stations, and I myself have seen on a six hours' trial the figure reached of 3½lb. per unit sold. If these figures have been already reached, and as we know that there are still many preventible losses, it is reasonable to suppose that we shall pretty easily reach with improved plant 3½lb.; but I admit anything in excess of this will be very difficult to attain, but this is no reason why I should not put 2½lb. as our ultimate goal, or as the 100 per cent. with which to compare our eventual economic efficiency.

I hope Mr. Schonheyder will not think that I intended to find fault with his water-meter when I stated that it is wise to frequently recalibrate it. On the contrary, I find his meter the best for this particular purpose of any that I have tried, and the necessity of frequent calibration arises from the very difficult conditions under which such a water-meter has to work.

I have to thank Mr. Hammond for his appreciation of the objects of my paper. He himself has done such good service in preparing and publishing statistics that he of all men can appreciate the difficulty there is in collecting these statistics.

I may say at once that I have met with uniform courtesy from everyone to whom I applied for information for this paper, the only case in which I was refused information being the company to which General Webber is responsible.

Mr. McLaren's remarks interested me because I know that he is a builder of record engines, and I was exceptionally pleased to hear that he was the builder of the engines which have shown such good results at Oxford.

Mr. McLean will, I hope, understand that I never intended to throw any doubt on the Oxford figures when I stated that they were almost too good to be true. Mr. McLean has gone the right way to obtain such figures—*i.e.*, by carefully measuring his losses and preparing his tables of statistics. This is the text on which I have endeavoured to preach to this Institution for the last six years.

I welcome Mr. Burnett's remarks, as I know him to be a boiler-maker of exceptionally high standing, and who has given more thought to the question of boiler economy than most people.

Returning to my ideal figures, I must point out to Mr. de Segundo that Messrs. Sultzer and other continental makers have been getting a consumption of 12½lb. of water per indicated horse-power for some years past, and I fully expect to hear that they have reached this figure in electric lighting stations in which these engines are used. It may be interesting to Mr. de Segundo to know that Messrs. Willans and Robinson are now giving guarantees with their condensing engines that the consumption will not exceed 13½lb. of water per indicated horse-power per hour.

The remarks of Mr. Shoolbred and other gentlemen who followed him on the subject as to the advantages of using accumulator storage in electric supply works are very apposite. This is a theme upon which I have often harped, and I am glad to find that I am so strongly supported. It is well known that the saving in wages from the use of accumulators is very considerable in the smaller classes of station, and even in the largest class—namely, the large central stations in New York—I am glad to say that Mr. Howell has been able to prove to the New York engineers that since he supplied accumulators to them their stations have been worked more economically—there has been a saving in fuel, and a large saving in the labour bill.

I must apologise to Mr. Dykes for the mistake in the efficiency of the Preston works. The correction was received, but was omitted to be made. Table No. VI. was corrected six or seven times, and it is small wonder that more mistakes have not occurred. The mistakes, however, only affect the B.T.U. per unit generated, and not per unit sold. I had no desire to animadvert on the accounts of this station; in fact, I hoped that someone would explain away what appeared to be such a large consumption of fuel, and I am glad that Mr. Dykes has been able to do this.

Prof. Unwin's remarks were very instructive. Although, as I have already said, I do not think that anything he has urged in regard to the Lancashire or Cornish boilers has any considerable bearing on their advantages for electric lighting stations, yet what is said about superheating is of the very highest importance, and is very encouraging to us; as I am sure after what he has said that we shall be able to adopt some form of superheater in most cases.

I am glad to note Mr. Peach's remarks as to the peculiarities and advantages of Mr. Paxman's Economic boiler. I can corroborate these remarks from personal experience.

Prof. Kennedy has given us very valuable information of the kind which I most appreciate—*i.e.*, his remarks greatly increase the value of my paper to those who may wish to use it as a work of reference. One of the important points raised by him is that he thinks that we cease to get any further advantages in reducing works cost so soon as our station is of a size to deliver 3,000 h.p. to 4,000 h.p. as a maximum load. I have for some years past required corroborative testimony on this point. I myself think that the limit of economical working is reached at an even smaller figure—say, 2,000 h p. In the old controversy as to the comparative advantages of several central stations *versus* one large external station, it has apparently not occurred to those who are always urging that our present system is wrong, that there is no appreciable advantage gained in increasing the size of a works above a certain figure. This figure I put at 2,000 h.p.; Prof. Kennedy puts it at 3,000 h p. to 4,000 h.p. If we are right, then the sole advantage of concentrating the works into one station and taking it outside the town really amounts to the saving in the cost of cartage of fuel, which advantage I believe to be very small.

This leads me to the question of the use of liquid fuel. Several speakers have thrown a doubt on the possibility of this being done successfully. I myself hold the other opinion. I think that even with very big stations if liquid fuel can be used for the stand by boilers, it will show a large economy over the use of coal for the same purpose, particularly when these stand-by boilers are only wanted for an hour or two in the course of each day's work. Several companies, including those with which I am closely connected, are experimenting in this direction, and I hope, when another paper is read on this subject, that I shall have some definite results to put before you. It does appear to me that if we can get up steam in a boiler at 20 minutes' notice, as can be done by the use of liquid fuel, we are approaching the ideal state of things as regards the boiler economy of an electric works. Further than this, I believe that as the ultimate capacity of all existing London works is limited by their room for putting in boilers, that the use of liquid fuel may increase the possible output of these stations 50 per cent.

I have now run rapidly through the criticisms which have been passed on my paper, and I must apologise to those gentlemen whose remarks, spoken or communicated, I have not been able to deal with this evening. I can only thank you heartily for the honour you have done me in taking such interest in the paper, and which has repaid me in every way for my trouble. I must repeat that my principal object in writing it was to elicit from those who work in these stations their real opinion as to the comparative advantages and disadvantages of the various types of the plant now in use. I think we have reason to be satisfied with the progress which has been made in boiler, engine, dynamo, and distribution economy, which may be summarised in Prof. Kennedy's statement that in a good station we now only use 4½lb. of Welsh coal per unit sold to the customers. We have only arrived at this point after nearly eight years of patiently studying the questions, by continuously measuring the losses and by tabulating these, and it is gratifying to record this improved result.

LIQUID FUEL.

In connection with Mr. Crompton's recent paper on the "Cost of Electric Energy," and the remarks made therein and during the discussion concerning the use of liquid fuel, the following abstract of a paper on "Liquid Fuel," read last week by Mr. G. Stockfleth before the Society of Arts, should be of interest.

The use of liquid fuel is by no means of recent date: it has for many years been pretty general in Russia, and the question cannot any more be considered as a problem which has to pass through its experimental stages. Before going further into the subject, it may be well to define which liquids can best be used as fuel. A good many oils might enter the list were it not for some indispensable requirements such as cheapness, absence of danger, capability for developing heat and undergoing complete combustion, without producing unpleasant smells, smoke, and dangerous and unhealthy gases, which conditions practically reduce the number to the oils derived from coal and from crude petroleum. The first named (oil derived from coal) is, however, not produced in sufficient quantities for even a limited consumption, and would be far too expensive to manufacture solely for fuel purposes. It is, therefore, to crude petroleum that we must turn for obtaining a suitable oil.

Crude petroleum consists almost entirely of a mixture of a great number of hydro-carbons differing in boiling point and density, and by being submitted to distillation, it gives a series of hydro-carbons known as gasoline, benzolene, kerosene, etc. It is not necessary here to give a detailed description of these different products; suffice it to say that the first distillate of crude petroleum, which evaporates at a low temperature, is the most inflammable, and gradually, as the temperature is raised, the less dangerous oils are distilled, until the temperature in the stills reaches 300deg. C. to 320deg. C.; at this point the distillate is called kerosene, and the residue (which in Russian is called astatki) forms the oil which so admirably answers the conditions for a good liquid fuel. It contains all the heavy hydro-carbons capable of creating heat, and the high temperature to which it has been exposed having freed it from all dangerous volatile liquids, guarantees its complete safety; a match or any other naked light

Digitized by Google

is immediately extinguished when plunged into it. In order to make it burn it requires special treatment, about which more shall be said presently. The Russian crude petroleum gives about 35 per cent. benzoline, gasoline, and kerosene; the remaining 65 per cent. is used for the manufacture of lubricating oils, and mostly as fuel. To give an idea of the extent to which it is used in Russia for locomotive, steamship, and even stationary boilers, it may be mentioned that the transport of astatki from Baku to the Caspian seaports and Astrakan amounted in 1892 to 107,361,435 poods, equal to about 3,000,000 tons; and, in addition to this, some 250,000 tons were shipped from Batoum. The statistics for 1893 are not yet available for reference, but will probably show an increase. In the above-mentioned tonnage the consumption in Baku, which amounts to more than 100,000 tons yearly, is not included. Astatki is the only fuel used at the boring of the wells, and for all distilling purposes, in some cases even for domestic use in warming and cooking stoves.

For boiler and distilling purposes it is necessary to create a larger and more powerful flame, and steam is used for forming it into a spray which is easily ignited, and then burns fiercely. Many injectors or pulverisators in Russia—called fasunkas—have been constructed and patented, but it has been found that the most primitively constructed pulverisators answer as well as the more complicated kinds. The apparatus used under the stills consists simply of two ¼in. pipes—one leading the oil from a tank, the other steam from a boiler. The ends of the pipes are flattened by a blow of a hammer, and then tied together with a piece of wire: the steam jet catches the outflowing oil and forms the spray. It is well to keep the oil a little warm to facilitate its passage in the pipes through which it descends by gravitation. This pulverisator gives entire satisfaction; the flame is powerful and bright, and not a drop of oil is wasted when once the flow has been regulated. No smoke or flame ascends the chimney—which, by the way, can be very short—as the steam jet itself creates sufficient draught. A somewhat neater appearance can be given to the injector when the oil-pipe is arranged inside the steam-pipe, and provided with a cast-iron or brass nozzle which can be shaped to give the flame any desired form.

Experiments have been made with compressed air for spraying the oil, but the results have not materially differed from those obtained with steam. Air must, of course, in any case have access to the flame, and openings on the front of the flue must be provided for its admittance. In most cases the hole in the furnace door through which the nozzle of the pulverisator is introduced, is sufficient for letting in the quantity necessary for the combustion. The action of the steam is therefore solely mechanical, and serves only for cutting up the oil in small particles, which, being surrounded by the necessary air for their combustion, catch fire before they reach the bottom of the flue. By using steam for spraying no oil accumulates in the flue when the flow is regulated, consequently a complete combustion of the oil takes place. If better results should be obtainable by using compressed air for spraying, the reason would have to be looked for in some chemical effect of the steam upon the oil, which to some extent could deprive the latter of its heat-creating properties. There is, however, no probability for this anticipation; if the steam had this effect it would already have done its work in the still, where superheated steam is admitted into the crude oil to facilitate the distillation of the different crude oil products. Looking at the question from the point of cost, it is not probable that the compressed air can be produced cheaper than the necessary quantity of steam taken direct from the boiler. It is, in fact, but a very small quantity which is necessary for doing this work when the pulverisator is properly constructed; and no case has come to my knowledge in Russia where the adoption of liquid fuel has augmented the quantities of feed-water used in a perceptible degree. The chief point in the construction of the pulverisator is to avoid waste of steam; that is to say, to construct the nozzle in such manner that every particle of steam takes care of a corresponding particle of oil. This object will best be secured when the openings for the steam, as well as for the oil, are made long and narrow, and are placed as close to one another as possible. All the different Russian constructions are made in this way. The openings are about 1¼in. long, and ¼in. to ⅛in. wide. As the oil sometimes contains paraffin, which is likely to choke this narrow opening, it is essential to have an arrangement by which steam can be led through the oil-passage to clean it out. The rest of the construction may be varied to suit particular cases, and with a view to facilitate and cheapen the manufacture. At the present time a great many ships on the Black Sea, and all steamers on the Caspian Sea, as well as all locomotives in Southern Russia, burn astatki.

The last years have seen a complete revolution in boiler-making. Water-tube boilers seem to be the type of boiler for the future. Various constructions are in the market, and a keen competition is going on for the best designs. Without going into details, it may be mentioned that the principal merits claimed are reduction of size and rapidity in raising steam of high pressure. Oil-firing greatly furthers these ends; fire-grate and ashpit can be done away with altogether, the length of the funnel can be reduced, and a system of water-tubes is better suited to the fierce fire of liquid fuel than the straight or curved surface of an ordinary thick boiler-plate. No boiler specially designed for liquid fuel is yet in the market, but the subject leaves certainly a wide field open for the boiler designer who, with liquid fuel, can obtain a flame which can be controlled, directed, and give uniformity much better than a coal fire, and which is less dependent upon air currents.

A disposition to use liquid fuel has already been shown in this country, both for locomotives and steamships. A certain number of locomotives, and even stationary boilers, have been fitted to use oil, and have burnt the tar oil which was obtainable. A small quantity also of astatki which had been shipped to this country has been employed for steamship use.

TELEGRAPHY, PAST AND PRESENT.

Before the Balloon Society on Tuesday, Mr. Charlton Wollaston, C.E., delivered an address on the above subject, Mr. W. H. le Fevre (president) occupying the chair. The President, in introducing the lecturer, mentioned that Mr. Wollaston laid the first telegraph cable between Dover and Cape Grisnez, under the concessions granted to the Bretts; that he was engineer at the introduction of the Cape and Natal land telegraphs; and that he continued the management of the former until they were taken over by the Colonial Government. Mr. Wollaston was one of the early practical developers of the Gower-Bell, or loud-sounding telephone, which was adopted by the General Post Office.

The lecturer first traced the early history of telegraphy from the year 1747, and referred to the various workers in this branch. Dealing with 1845, he described the first submarine telegraph—viz., that from Dover to France. The concession was granted in 1847, but the revolution of that time placed the Provisional Government into the hands of Lamartine, and later into the hands of Louis Napoleon, afterwards Emperor. By each of these the concession given to the Bretts was confirmed (by Napoleon, in 1849, who extended the time), but no one would take up the scheme, and no one believed in it. Nevertheless, the first cable was put in hand in 1850. On August 28, 1850, one end of the new cable was attached to a pile of the Admiralty Pier at Dover, and the adventurous expedition started. On the following day the *Times* announced that communication had been established to Cape Grisnez.

The jest of yesterday had become the fact of to-day, and now telegraph cables thousands of miles long encircled and crossed the world. The earlier part of this century was one of surpassing interest in the advance of electrical knowledge, and all the requirements for an electric telegraph were at hand—viz., the voltaic battery, the electromagnet, the multiplying coil, the magnetic needle, together with the knowledge that a suspended magnetic needle could be deflected by a galvanic current passing through a fixed coil adjacent to it. The lecturer said that it was not to be wondered at that numerous devices for carrying on the telegraphic communication by means of electricity were proposed and shown by many philosophers and experimentalists in different parts of the civilised world, and that its present extension and usefulness should command and regulate the commerce and destinies of nations.

SPECIAL REPORT ON THE HERMITE SYSTEM OF SEWAGE TREATMENT.

Since the issue of Dr. Kelly's report on the Hermite system at Worthing, and which was published in this journal at the time, we have reproduced the conclusions arrived at by Dr. Piton in regard to the experiments made with this method of sewage treatment at Brest. We now make no apology in giving a few extracts from the lengthy report prepared by the *Lancet* special analytical commission appointed to deal with the experimental plant at Worthing and with the system in the laboratory. After describing the plant at Worthing, the report goes on to deal with experiments relating to the chemical and bacteriological examination of the electrolysed fluid at varying strengths, and of the treated sewage effluents, and to the behaviour, chemical and bacteriological, of certain compounds of similar chemical composition:

We have shown in the foregoing results that electrolysed sea-water contains probably as its chief active constituent hypochlorous acid, resulting from the partial dissociation of magnesium hypochlorite, and that it is fairly stable under ordinary circumstances; that it is a powerful bleaching liquid, being superior in this respect to bleaching powder solution, but not to a solution of bleaching powder of equal chlorine value, in which the hypochlorous acid has been liberated by the addition of a weak acid (CO_2 or others, in weak solution); that it is also a powerful deodoriser; and that in all probability these properties are due to the united action of oxygen *in statu nascendi* and chlorine. These, in brief, are the chemical properties of electrolysed sea-water, and it remains for us to consider what effect for good or for evil such a liquid of definite strength would have when mixed in a certain proportion with fæcal matter. It deodorises, but does not destroy nor remove, organic matters, although there is little doubt that certain of them are partially changed, and most probably those which are more readily putrescible. While these things are true and so far satisfactory, there must also be certain drawbacks in the system which are likewise indicated in these experiments. Electrolysed sea-water, for instance, is rapidly reduced in strength by common newspaper, and as this is an almost invariable accompaniment of human dejecta its presence in the sewer must seriously affect the activity of the liquid, even if it does not withdraw the active constituent entirely. Indeed, the entire contents of a sewer rapidly appropriate the chlorine strength of the liquid. The same observation applies to the soap or domestic waste, etc., which rapidly "kills" oxygenated

Digitized by Google

chlorine compounds. Again, it can only be supposed that deodorisation, not to say sterilisation, is complete when the chlorinated body is in excess, and an effluent containing free chlorine or its equivalent is inadmissible to rivers. The expense, moreover, in inland towns would be greater, since it would be necessary either to carry sea-water or to prepare it artificially. M. Hermite's proposal is to establish a producing centre in the towns and to supply the liquid through pipes into all the streets and houses much in the same way that water and gas are at present supplied. The adoption of such a scheme in any place would no doubt lead to a sanitary condition of things hitherto unreached, but many excellent advances could be made in the same direction, it should be remarked, if cost were not an item which so often bars the way. Apart, however, from such a scheme, there is no doubt that the production from sea-water of a powerful bleaching agent and deodorant is an innovation which should afford very material aid to sanitary progress. Thus, for many purposes, the substitution of electrolysed sea-water for other and more expensive agents in our seaside towns and villages would doubtless confer many advantages. It could be used, for example—with desirable effect, doubtless—to flush the headings of drains and sewers; it could be discharged into sewage outfalls; and, lastly, the system could be applied on a small scale for the sanitary treatment of hospitals, barracks, etc., by means of an automatic electrolyser worked from a central electric supply. It should be added that except as regards what has already been published in our columns, no particulars in regard to the actual cost of production have as yet been furnished by the originator of the main idea.

Antiseptic Action of Hermite Solution diluted with Distilled Water.

TYPHOID.

Available gramme of chlorine present per litre.	Immediate.	Five minutes.	Ten minutes.	Fifteen minutes.	Thirty minutes.	One hour.	Twenty-four h're.	The original dilutions of Hermite fluid were re-inoculated with B. typhosus on the fifth day, and after standing 24 hours were tested by inoculations into broth.
0·60	+	—	—	—	...	..	...	...
0·30	+	—	—	—	...	...	...	...
0·30	...	—	...	...	...	...	—	+
0·20	+	—	—	—	...	...	...	...
0·17	+	+	—	—	—	...	...	...
0·15	+	+	+	+	...	...	...	...
0·15	...	+	...	+	...	...	—	+
0·13	+	+	...	...	...	...	...	...
0·12	+	+	+	+	...	...	...	...
0·10	..	+	...	...	+	+	—	+
0·05	...	+	...	...	+	+	+	+

The question now comes to be: are we correct in assessing the antiseptic value of the Hermite solution in terms of available chlorine, as in that case a solution of chlorine water of equivalent strength should exert a similar action? This question we have attempted to answer in the following table:

Antiseptic Action of Chlorine Water.

TYPHOID.

Gramme of available chlorine present per litre.	Five minutes.	Twenty-four hours.	The original dilutions reinoculated on the third day with bacillus typhosus were, after standing 30 minutes, again inoculated into broth.
0·70	—	—	—
0 35	—	—	—
0·23	—	—	+
0·14	+	—	+
0·10	+	—	+
0 05	+	—	+
0·03	+	+	+

On comparing this table with the results obtained with Hermite solution, given in the first table, it will be found that the two correspond almost exactly, or, at any rate, vary only within the limit of experimental error. Thus 0·17 and 0·05 of Hermite solution give a positive result in five minutes and 24 hours respectively where 0·14 and 0·03 of free chlorine are required to produce the same results. We are accordingly warranted in concluding that we may generally estimate the antiseptic value of the different oxychlorine compounds present in the Hermite solution in terms of their available chlorine or oxidising power, although we are unable to define to what extent the antiseptic action is due directly to the chlorine or to its indirect action as an oxidising agent. They however, no doubt vary very much as regards the readiness with which they exert this action, some being more stable than others, and it would also seem that some of them are able to form comparatively stable compounds with other substances, by means of which their antiseptic power may be retained almost indefinitely; thus we have found that samples of broth which had received comparatively small quantities of the Hermite solution, even after seven weeks contained a sufficient amount of available chlorine to be titrated in the form of iodine by means of thiosulpate of sodium. We have observed also that the effluents from Yard B, which appeared at first to continue to fall in their available chlorine, seemed after a time to remain stationary. If the antiseptic value of the fluid, then, depends merely on the available chlorine, may we not substitute a solution of bleaching powder of equivalent strength as being probably much less expensive and more easily prepared. Our experiments with typhoid cultures, however, would seem to indicate that at least half as much again of this solution is required to produce the same result in the same time, although from its greater stability it is perhaps more efficacious when allowed to act over a longer period. Our "artificial" Hermite solution, prepared by passing carbonic acid gas through the bleaching powder, gave varying results, due to some factor which for the present escapes us, and although the bleaching powder solution is rendered slightly more powerful, still it could not be depended upon to exert, constantly, an equivalent action to the Hermite solution. The influence of the carbonic acid gas is, however, brought out in a most striking fashion by our experiments on the very resistant spores of bacillus mesentericus vulgatus.

If we compare the action of the Hermite solution as an antiseptic with carbolic acid, the superior efficiency of the former is so evident, even in solutions of relatively great dilution, that we are left in no doubt as to which is to be preferred. The only substance used as an antiseptic, which operates in solutions of such great dilution, is corrosive sublimate ($HgCl_2$), and, although the laboratory experiments might appear to give it a certain advantage, we are confident that the facility with which it unites with organic bodies, and thereby becomes inert, would render it very much less efficacious than the Hermite solution for general use as a practical disinfectant. The electrolysed sea-water, or our "artificial" Hermite solution, appears, indeed, while exerting a specific disinfecting action on the organisms, at the same time to be used up and destroyed to a much less extent by the organic matter present than any other disinfectant with which we are at present acquainted.

In applying the results which we have obtained from our examination of the Hermite system carried out on the spot and our more extended laboratory experiments, it must first be stated that all investigators who have occupied themselves with the question of sterilisation of stools have found it most difficult to render them absolutely sterile in a short space of time by the ordinary means available, and have accordingly addressed themselves more to the solution of the problem of what would be sufficient to free them from the pathogenic germs, such as those of typhoid fever and cholera, which might be present. We are quite satisfied from our examination of the effluent in Yard B that all such would be effectually dealt with, as the more resistant bacterium coli commune appears to be destroyed. It is probable from a number of observations which we have made, which it is unnecessary for us here to record, that the titrations of the effluent do not really indicate fairly its antiseptic power, but that this is really much greater than the arsenious acid method would lead us to expect. It will also be noticed that the higher strengths of solution supplied from the distribution tanks do not so markedly raise the amount of available chlorine in the effluent as might be expected, and this is to be accounted for by the more unstable portion of the solution being at once converted into some other form, which, although not indicated by the arsenious acid titration, may still be effective as an antiseptic. The bacteriological results also are not improved to such an extent as to warrant us in recommending the adoption of such strong solutions of the Hermite fluid, as this would necessarily entail no inconsiderable addition to the cost involved in the adoption of the system; a system of between 0·50 and 0·60 gramme chlorine per litre is all that we should consider necessary to effect the proposed objects of this method of sewage treatment. The adoption of any mixed system in which the house water, even without the storm water, is allowed to enter the drum in which the sewage undergoes treatment must, so far as we can see at present, always be accompanied by the danger that the whole object of the scheme may be rendered futile from the fact that we must rely wholly upon the care and judgment of the inmates of the household for the addition of sufficient quantities of the antiseptics from the sink. The application of the solution for watering the streets does not, we think, require serious consideration. The question of the flushing of the drains requires, however, further investigation, as although the direct antiseptic action would probably be small, the deodorising and cleansing effects might have some value, but this can only be decided by direct experiment. The application of the system to hospitals in the complete form recommended by M. Hermite has much to be urged in its favour. The regular disinfection of all objects which have been exposed to contamination in the wards or in the side rooms by such a powerful disinfectant, which would always be at hand, must minimise the risk of the spread of infection which emanates from all such centres of disease. Its substitution in laboratories for the ordinary disinfectants now in use also follows as a natural consequence, and, inasmuch as what may be termed the "artificial" Hermite solution can be made to any strength at an insignificant cost, whilst the electrolysed sea-water can be raised to a strength of only a little over one gramme chlorine per litre, and this at an ever relatively increasing cost, it offers very obvious advantages for such purposes.

The development of the Hermite system must be regarded as merely one of the signs of a distinct movement in sanitary science which for some time has been manifesting itself in other directions. The idea of cutting off the prime etiological factor by sterilising whatever is supposed to contain the infective agent is at present the main stand-by of preventive medicine, Mr. Henman having

Digitized by Google

quite recently even applied the idea to the prevention of the spread of infection from fever hospitals by means of a system of ventilation in which the air is subjected to processes of filtration and sterilisation before it is allowed to pass outside the infected buildings; this is also seen very clearly in the strong tendency of modern sanitation as regards cremation of cadavers. On the other hand, another system—that of Mr. Seymour Haden—appears to advance in quite an opposite direction, inasmuch as the burial of the body in as unprotected a fashion as possible is resorted to in order that the processes of putrefaction may proceed more rapidly and the organism be resolved into its component elements. In a similar way Mr. Scott Moncrieff, instead of endeavouring to "sterilise" the sewage, has introduced a system in which he proposes to facilitate the processes of putrefaction by placing the sewage under specially favourable conditions to bring about that end, so that the complex organic matter may be broken down as rapidly as possible into a series of lower compounds, which can be taken advantage of for agricultural purposes, whilst at the same time he relies upon the vigorous action of the putrefactive organisms and the conditions produced by them to destroy or render inert any pathogenic micro organisms which may happen to be present. As to which of these two methods will finally triumph, or whether they may not in the future be combined and come into common operation, it is at present somewhat difficult even to venture an opinion.

PHYSICAL SOCIETY.

At a meeting of this society on May 25th, Prof. A. W. Rücker, F.R.S., president, in the chair, **Prof. W. Ramsay, F.R.S.**, read a paper on "**The Passage of Hydrogen through a Palladium Septum, and the Pressure which it Produces.**" After referring to the analogy between osmotic pressure of solution and the behaviour of hydrogen and palladium, the author described the apparatus he had used in his experiment, and showed it in operation. A vertical platinum tube provided with a palladium cap is enclosed within a glass vessel through which hydrogen or other gases may be passed, and outside the glass is a vapour jacket by means of which a constant temperature can be maintained. The lower end of the platinum tube communicates through a graduated capillary tube with an adjustable manometer, which enables the volume of the enclosed gas to be kept constant. Great precautions were taken for ensuring purity and dryness of the gases used. After filling the palladium and platinum tube with dry nitrogen at atmospheric pressure and the desired temperature, hydrogen was passed through the glass vessel. Some of the hydrogen permeated the palladium walls, thus increasing the pressure inside. After some time (usually an hour or so) the pressure attained a steady value, and the total increase was then observed. Experiments were made with air, nitrogen, nitric oxide, nitrous oxide, carbon dioxide, carbon monoxide, and cyanogen in the palladium tube, and in some cases the hydrogen was diluted with nitrogen. In all cases the maximum pressure of the hydrogen within the tube was less than that of the hydrogen outside the tube, as will be seen from the following table, which shows the ratio of these pressures under various conditions:

Gas originally inside tube	Gas passed outside tube.	Temperature.	Ratio $\frac{\text{Internal hydrogen pressure}}{\text{External hydrogen pressure}}$
Nitrogen..	Hydrogen	280° C.	0·9053
,, ..	,,	335°	0·8984
,, ..	,, 50 % (rest N.)	,,	0·9362
,, ..	,, 25 ,,	,,	0 9344
Carbon dioxide ...	Hydrogen	280°	0·9621
Carbon monoxide	,,	,,	0·9545
Cyanogen.	,,	,,	0 9693

After the palladium had been used once or twice it became coated with mercury (vaporised from the manometer) and lost its permeable properties. It was found necessary to heat the tube to remove the mercury, and then dissolve off the oxide of palladium thus produced, after each experiment. The permeable nature of palladium was found to depend greatly on the temperature, for at 232deg. C. the passage of hydrogen was so slow that the internal pressure was still rising after 10 days; at 330deg. the passage was very rapid. An attempt to use the apparatus for giving a continuous indication of the amount of hydrogen in coal-gas failed because the palladium did not retain its activity sufficiently long. Other experiments showed that nickel is impervious to carbon monoxide. In the latter portion of the paper the author discusses the various "so-called" explanations which have been given of the phenomena, but finds none satisfactory. Experiments on the absorption of gases by platinum and other metals are in progress with a view to the further elucidation of the subject. **Mr. Mond** thought the fact that rise of temperature accelerates diffusion tended to confirm Graham's view that the gases pass through openings in the solid, for increase of temperature would widen any pores which might exist in the metal. The **President** enquired whether the author's argument against the possibility of palladium hydride condensing in the pores of the metal, because of its being unstable at the temperatures employed, would be affected by the fact of water being capable of existing in contact with glass at temperatures much above boiling point. In reply, **Prof. Ramsay** said the president's suggestion might be true, but if so another condition must be fulfilled—viz., that the hydrogen molecules must be split up into the atomic or nascent state.

A paper on "**The Expansion of Rarefied Gases,**" by **Prof. W. Ramsay, F.R.S.**, and **Mr. E. C. C. Baly**, was read by the latter. In the first part of the paper a historical summary of previous researches on the subject is given, and the chief sources of error pointed out. The method employed by the authors was to have two McLeod gauges connected with a pump, and arranged so that both could be trapped under exactly the same pressure. One of the gauges was surrounded by a vapour jacket at about 130deg. C., whilst the other was cold at about 13deg. C. After both were trapped, the hot gauge was allowed to cool, and the readings of both taken. From these observations the coefficient of expansion of the gas used could be calculated. The experiments also served as tests of the reliability of the McLeod gauge under different conditions. For air and carbon dioxide the gauges proved quite unreliable, whilst for hydrogen they were very satisfactory. With carbon dioxide the surface condensation was so large as to make the observations worthless, but hydrogen suffered no condensation between pressures of 650mm. and 0·000076mm. Great difficulty was experienced in filling the gauges with pure hydrogen, but when accomplished the expansion was found to be normal ($\frac{1}{273}$) down to 0·4mm. pressure, and diminished to $\frac{1}{300}$ at 0·07mm. Oxygen, however, gave a coefficient of $\frac{1}{281}$ at 5mm. pressure, $\frac{1}{316}$ at 2·5mm., and $\frac{1}{313}$ at 1·4mm. At 0·7mm. its behaviour was most erratic, there being as much as 15 times the amount of gas trapped in the gauge at one time as at another. This confirms C. Bohr's observations on the anomalous behaviour of oxygen about this pressure. For nitrogen the values of the coefficients found were $\frac{1}{310}$ at 5mm., $\frac{1}{304}$ at 1·1mm., and $\frac{1}{312}$ at 0·66mm. At small pressures the elasticities of hydrogen, nitrogen, carbon dioxide, and air increase with decrease of pressure, but in oxygen the reverse holds. Examining the consequences of this increase of elasticity in the light of the kinetic theory of gases, the authors point out that it means an increase of internal energy, and suggest that this may be the cause of phosphorescence in high vacua.

The **President** announced that the discussion on the last paper would be taken at the next meeting, after proofs had been distributed to members.

LEGAL INTELLIGENCE.

MUIRHEAD AND OTHERS v. THE COMMERCIAL CABLE COMPANY, LIMITED.

It will be remembered that in the report of this case given in our issue of May 4, it was stated that a day would be fixed for his Lordship to bear counsel's arguments upon the question as to whether or not the plaintiffs—who were the successful parties—were entitled to interest and at what rate upon the amount recovered? The question involved a very considerable sum. The learned Judge heard the arguments in his private-room early in May, and on May 11 he delivered judgment in favour of the defendants.

Mr. Justice Kennedy said: In this case there was a question, which was discussed after judgment had been given for the plaintiffs upon the main point in the case, as to whether or not the plaintiffs were not entitled to interest, and he had been referred to several decisions upon the point, the latest of which was one that was in his mind when the matter was first mentioned—viz., the London, Chatham, and Dover Railway Company *v.* the South-Eastern Railway Company. In the present case he did not think there was any difficulty in the way of the plaintiffs upon the question as to whether the amount to be paid by the licensees—the defendants to the licensors—the plaintiffs under the agreement of January 2, 1884, was a sum certain or not; therefore, in his opinion, the case referred to did not apply, for in it the decision had turned upon the question as to whether there was a debt or sum certain within the meaning of Will. IV., c. 42, section 38. But the case which was a binding authority upon him, and which was followed by the Court of Appeal in the London, Chatham, and Dover Railway Company *v.* the South-Eastern Railway Company was the Merchant Shipping Company, Limited, *v.* Armitage, and the question was whether or not—that decision of the Exchequer Chamber being binding—this agreement does or does not make the sum upon which interest is claimed a sum which is, by the terms of the agreement to be paid at a certain time? The words were, he said, "sum certain payable, by virtue of a written instrument, at a certain time." Now, as he understood the effect of that decision, and the judgment of Lord Blackburn—the dissentient judgment in the more recent case of Duncombe *v.* the Brighton and Norfolk Hotel Company—it was that it is not sufficient that the "certain time" should be a time ascertainable by calculation from the written instrument, but must be a "certain time" definitely fixed by the instrument itself without the necessity of subsequent ascertainment—in short, that it requires nothing more in order to fix the date than to look at the instrument itself. He had, therefore, to look at this agreement and see whether the time for payment was a certain time by virtue of that instrument, and, in his opinion, it was not, and therefore, on the authority of the Merchant Shipping Company *v.* Armitage he must refuse interest to the plaintiffs. His reason for

Digitized by Google

doing so was, shortly, that article 5 (of the agreement), dealing with the question of time, fixed the royalty in these terms: "The royalty, determined as above mentioned, shall be payable in London quarterly, and shall commence to run from the expiration of the first period of 15 consecutive days during which the inventors shall have maintained their said apparatus in good working order on the company's cables or cable, and after a realisation of an increase of 30 per cent. at least in the power of transmission of the cables shall have been determined between the parties," and then there was further provision. His Lordship said that, looking at the method of ascertainment of time as prescribed in that article, it seemed to him quite impossible to distinguish this case from the one he had referred to as decided in the Exchequer Chamber For those reasons his Lordship said he must disallow the plaintiffs' claim for interest. Judgment would therefore stand for the amount claimed, less, as he understood it, the sum of £135, which had been paid into Court and which the plaintiffs were entitled to take out.

Mr. Pollard reminded his Lordship that there was another point on the question of interest, which did not depend upon the written agreement, but upon the express claim in the writ.

Mr. Justice Kennedy said that upon that point he was quite clear that the fact of there being a claim and demand in a writ was not a demand within the operation of the section (3 and 4 Will. IV., c. 42, s. 28), which constitutes a demand. He was, therefore, against him on that point as well.

Mr. Pollard argued the question of interest on the plaintiffs' behalf; and Mr. Walter appeared for the defendants.—*The Times.*

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,287.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 27th ult. amounted to £874.

Brazilian Submarine Telegraph Company.—An interim dividend of 3s. per share for the quarter ended March 31 is announced, payable on June 22.

Plymouth.—Messrs. Hearder and Son, of Plymouth, have been chosen to fix one of their improved lightning conductors to the new church at Budleigh Salterton.

Change of Address.—The rapid extension of their business has necessitated Messrs. Bennett and Druce to remove to larger and more convenient offices at 30, Winckley-square, Preston.

Bristol.—The Electrical Committee of the Town Council met at the Council-house on Friday, Mr. Charles Wills in the chair. The committee decided to meet once a month only during the summer months.

Shoreditch.—The Vestry have affixed their seal to the contract for the purchase of the Pitfield-street site, for the erection of a dust destructor, baths, library, and electric lighting station, at an estimated cost of £100,000.

Sheffield.—The Electric Light and Power Company commenced on Monday the work of laying underground mains westward, and it is expected that the current will be available to consumers during the ensuing autumn.

Claybury Asylum.—On Wednesday, Mr. Ross Cotton, A.I.E.E., was presented by the electric lighting staff with a silver-mounted walking-stick, a cigar-case, and an illuminated address on the occasion of his leaving the above station.

Exeter.—The Devon Standing Joint Committee have accepted the offer of the Exeter Electric Light Company to instal the electric light at the central police station for £55, and to supply current at an annual estimated cost of £39.

Portsmouth.—Seven tenders have been received by the Portsea Guardians for providing and fixing electric fittings to the Guardians' office in St. Michael's-road. Messrs. Walker and Co., of Queen-street, Portsea, quoted the lowest price, £67, which has been accepted.

An Electrician Required.—A practical working electrician is required to take charge of an installation of about 2,000 incandescent and 50 arc lamps. Applications are to be made by letter to No. B 22, *Electrical Engineer* Office, 139-140, Salisbury-court, London, E.C.

Tenders for Acton.—The Acton Local Board invite tenders by the 5th inst. for the transfer of the provisional order obtained by them, and for the installation of electric lamps in the streets. Further particulars may be obtained at the office of Mr. D. J. Ebbetts, surveyor.

Tenders for Coventry.—The Town Council invite tenders for the erection of an electric lighting station. Plans and specifications may be seen on application to Messrs. George and Isaac Steane, 22, Little Park-street, Coventry. Tenders must be delivered by the 13th inst.

Yeadon.—The Board of Trade Provisional Order Bill, authorising the Yeadon Local Board to make electricity, and to supply the current through mains to consumers by meter, passed the Examiner in the House of Lords on Standing Orders on Tuesday, and was ordered to be reported for second reading.

City and South London Railway.—The receipts of the Company for the week ended May 27 were £931, against £844 for the same period last year, or an increase of £87. The total receipts for the first half-year of 1894 show an increase of £564 compared with those for the corresponding period of 1893.

Fleetwood.—The clerk mentioned to the Improvement Commissioners at the last meeting that tenders for the electric light station, etc., were about being received. The 26th of May was named as the last period for recognising tenders.

Hanley.—The local authorities at Hanley are proceeding slowly towards completing the arrangements for the public lighting of the town by electricity. The light is being used in shops and in the free library, and will soon be available for use in the other public buildings and the streets. The street lamps have been tested.

Ship-Lighting.—The s.s "Maria Herrara," built by Messrs. David J. Dunlop and Co., Inch Works, Port Glasgow, for a Havana firm, has been fitted throughout by Messrs. Claud Hamilton and Co., Limited, with the electric light, including the masthead and side-lights, as well as a powerful portable light for working the cargo.

Tenders for Alford (Lincs.).—The Inspectors for Lighting the Town of Alford are prepared to enter into a contract for lighting the town with gas or other light from August 14 to May 14, 1895. Tenders will be received up to June 9 at the office of the Inspectors, West-street, where all particulars may be obtained. Mr. W. E. Rushton is the clerk.

Norwich.—In connection with a discussion on the subject of the public gas lighting of the town, Mr. Wild, one of the members of the Town Council, stated at a recent meeting that the experiments in the use of the electric light in St. Andrew's Hall during 25 organ recitals had resulted in a saving of from 20 to 25 per cent. as compared with gas.

Tenders for Grimsby.—Tenders are invited by the Grimsby Urban Sanitary Authority for the lighting of the public streets of the borough for a term of one year. Forms of tender, copy of specification, and any further information, may be obtained on application to Mr. Marshall Petree, borough surveyor, Town Hall. Tenders are to be delivered at the town clerk's offices, West St. Mary's-gate, by June 8.

Salisbury.—In our last issue reference was made to the negotiations proceeding between the Town Council and Mr. W. H. Gramshaw on the subject of electric lighting. The Town Council have now unanimously assented, on the request of Mr. Gramshaw, to an application by the Salisbury Electric Light and Supply Company, Limited, to the Board of Trade for a license to supply the district with the electric light.

Mill-Lighting.—Messrs. Bennett and Druce, of Preston, have received instructions from Messrs. Ormrod, Hardcastle, and Co., Limited, Bolton, for the complete lighting of their mills. The plant will consist of a 78-kilowatt dynamo driven off the main engine, and about 1,250 lamps of 16 c.p. A pilot plant, consisting of a "Marshall" vertical engine and a 100-light dynamo, will also be installed to supply the lamps required during the daytime.

Telegraphic Apparatus Required.—The North-Eastern Railway Company invite tenders by the 5th inst. for the supply of the undermentioned articles in such quantities as they may require during the six months ending December 31, delivered, carriage paid, at the company's telegraph stores at York—viz., (1) telegraph apparatus, (2) telegraph wire and line stores. Forms of tender may be obtained on application to Mr. Graves, Telegraph Department, York.

Electricity Works Inspector.—The Commissioners of Sewers are about to appoint an inspector under the Electric Lighting Acts, 1882 and 1888, and the City of London Electric Lighting Provisional Orders A statement of the duties may be had on application at the office of Mr. Henry Blake, principal clerk, Sewers Office, Guildhall. The salary will be £250 per annum. Applications must be addressed to the clerk to the Commissioners of Sewers, Guildhall, E.C., and delivered by June 12.

Bridlington Quay.—The Bridlington Local Board have decided to light up the sea-front from the north end of the Prince's Parade to the north end of the Beaconsfield sea-wall by electricity, at an estimated cost of £275. The Prince's Parade has been lighted by electricity for the past three seasons, and it has proved such a success that the Board have determined to extend this mode of lighting. Seven arc lamps of 2,000 c.p. each will be used, and supplied from the Board's station on the Prince's Parade.

Belfast.—On Monday a meeting of the Electric Lighting Committee of the Town Council was held to consider the tenders for the erection of the new central electric lighting station in Chapel-lane. Seven tenders were submitted, that of Messrs. M'Laughlin and Harvey being accepted, subject to it receiving the approval of the engineer and confirmation by the Council. The committee are insisting upon all the arrangements being carried out with the utmost despatch, so that the electric light may be available by September 1.

Dundridge.—An electric light installation has been completed by Messrs. Veale and Co., Limited, of St. Austell, for Mr. Robert Harvey, of Dundridge, near Totnes. The mansion is extensive, and altogether 135 lamps, varying from 8 c.p. to 32 c.p., have been installed. The current is generated by a Crompton dynamo, driven by a Crossley oil-engine equal to 7 h.p. actual. The current is used to charge storage batteries consisting of 53 cells. The lamps have been selected with a view to the special purpose which they are to serve.

Tenders for Bedford.—As stated in our last issue, the Corporation of Bedford invite tenders for the construction, supply, and laying down of the necessary plant and mains for the supply of electricity in the borough. Specifications may be obtained from and plans may be inspected at the office of Mr. F. H. Medhurst, B.Sc., M.I.E.E., 13, Victoria-street, Westminster, S.W., on pay-

Digitized by Google

ment of £2. 2s. per section, which will be returned on receipt of a *bonâ fide* tender. Tenders are to be delivered at the office of Mr. T. S. Porter, clerk. Town Hall, Bedford, by June 16.

Worcester.—The Watch Committee of the Town Council have resolved to recommend the Council to fix the charge for the private supply of electricity at 5d. per unit. It has also been resolved to recommend a cash discount on quarterly accounts of 5 per cent., and that the following scale of discount on annual bills should be allowed: £25 3 per cent., £50 5 per cent., and £100 and over 10 per cent. The proposal for suspending arc lamps over the roadways has been abandoned, and the Brush Company have been requested to submit designs with prices of brackets for fixing lamps on houses in the streets.

Provisional Orders.—The Lords had before them on Tuesday the Electric Lighting Provisional Orders (No. 3) Bill, the object of which is to confirm certain provisional orders made by the Board of Trade under the Electric Lighting Acts, 1882 and 1888, among them being an order empowering the Shropshire Electric Light and Power Company (Shropshire) to use electricity. Formal proof having been given, it was decided that the standing orders had been complied with, and the Bill will in due course be reported for second reading. In the case of the Electric Lighting Provisional Orders (No. 4) Bill a similar course was adopted.

A Rise in Shares.—"In the course of the past few days," says the *Financial Times* of Friday last, "there has been a demand for the securities of the City and South London Electric Railway Company, and the quotations have all advanced. The debenture stock has risen five points, to 115, the preference shares ¼, to 11¼, and the ordinary stock is three up, at 33. There is no special reason for the movement beyond the fact that the stocks are comparatively cheap. The traffics also have been showing well of late, there being a total increase for the first 19 weeks of the present year of £364 on an aggregate take of about £17,000."

Consolidated Telephone Construction Company.—The report of the Consolidated Telephone Construction Company, Limited, for the year ended March 31 states that the operations show a manufacturing profit of £3,070, and a net profit of £2,577. With the amount carried forward, a balance of £3,695 is left for disposal after making prevision for doubtful debts. The directors propose to pay a dividend of 2 per cent. for the year, to write off a further £64 from the cost of the new building, 10 per cent. from the furniture account, and £15 from goodwill, patent rights, etc., and to reserve £122 for rentals paid in advance, carrying £1,301 forward.

Chesterfield.—A similar electric lighting provisional order to that of Buxton has been introduced into the House of Commons on behalf of the Chesterfield Corporation. The area of supply is to be the area of the borough of Chesterfield. The streets to be supplied within two years of the commencement of the order are Market-place, New-square, Lower-pavement, High-street, and Packer's-row. The general powers and charges for electric light are precisely similar to those proposed to be enacted in the case of Buxton. The order, which has come before Mr. Mellor as an unopposed measure, has been ordered to be reported for third reading.

Buxton.—The Buxton electric lighting provisional order, which has come before Mr. Mellor, chairman of Ways and Means, at the House of Commons as an unopposed measure, has been granted by the Board of Trade under the Electric Lighting Acts, 1882 and 1888. The object of the order is to empower the Local Board of Buxton to manufacture and supply electricity over the whole of their district. Consumers are to be charged by the actual amount of energy supplied, the rates for the electric light being a minimum of 13s. 4d. per quarter, and for every unit above 20 units 8d. per unit per quarter. Mr. Mellor has passed the order for third reading.

Aberdeen.—The electric light station in Cotton-street was recently thrown open to the inspection of the public. At a meeting of the Gas Committee of the Town Council a letter was read from Prof. Kennedy, giving results of the working of the electric light at the station, from which it appeared that there had been used throughout the area 4,677 units, and at the station 205 units. There had been generated 5,522 units, and the difference between the consumption and output was accounted for by loss sustained in the working through the batteries. The income was £114. 17s. 1½d., and the outlay for wages, etc., was £175. 5s. 3d. There are now 2,950 lamps throughout the city, and the street lamps, which are equal to 172 ordinary lamps, consume about one-seventeenth of the total amount of electricity used.

Tenders for Ayr.—As will be seen from our advertisement columns, the local authority of the burgh of Ayr invite tenders for the supply and erection of the following plant: Section A. Boiler-house plant, including boilers and fittings, mechanical stokers and motor, forced draught apparatus, economiser, feed pump, injector, water-tank, steam, feed, blow-off, and sundry pipes and valves. Section B. Engine-house plant, including steam alternators, steam dynamos, independent condenser, exhaust-pipes, oil-filter, fittings, etc. Section C. Switchboard and instruments. Section D. Underground work, including cables, culverts, brick chambers, and trenching. Section E. Transformers and boxes. Section F. Arc lamps and posts. Section G. Meters. Section H. Overhead crane. Tenders must be sent in by June 23.

Preston Gas and Electric Lighting Bill.—This Bill was on Tuesday before a Select Committee of the House of Commons. It authorises the gas company to construct additional works on a site to the west of the new docks and adjacent to the river; to raise £200,000 by shares and £50,000 by loan, to extend the limits of supply, and to make application, should the company think fit, for a provisional order under the Electric Lighting Acts. The Bill is opposed by Lieutenant-Colonel Fielden and by the Corporation. The latter maintain that the extension of the works is unnecessary, and also that the site chosen for the extension is a bad one. They also oppose the granting of powers to apply for a provisional electric lighting order, the supply of the electric light being already in the hands of a company. The hearing was again adjourned.

Islington.—The Electric Lighting Committee have considered the designs for the electric light station. The successful competitor is Mr. A. Hessel Tiltman, F.R.I.B.A., 70, Torrington-square, W.C. The present plans (which form a first portion only of the future contemplated building) provide the following accommodation: two boiler-houses, each 112ft. by 56ft.; two dynamo and engine rooms, each 112ft. by 44ft.; arc lighting plant-room, 62ft. by 40ft.; testing-room, oil and waste stores, general stores, switch-room, machine and fitting shop, smith shop, stokers' mess-room, cloakroom, etc.; coal store, water-tank for some 120,000 gallons, and offices for the departmental engineers and the general clerical staff. The estimated cost of this first part of the building is about £20,000, and the work is to be immediately proceeded with.

Exhibition at Ashford.—The recent Trades and Inventions Exhibition held at Ashford from April 25 to May 5 last was lighted throughout by electricity, the installation having been carried out by Mr. C. Rawlings, of Maidstone, on behalf of Mr. Richard Dann, of the same town. The installation consisted of a 30-h.p. Tangyes gas-engine, driving a Crompton 200-ampere 110-volt dynamo; a 21-h.p. Tangyes "Archer" vertical steam-engine, driving a Crompton 130-ampere 110 volt dynamo; 20 8-ampere "Byng" arc lamps; and about 280 incandescent lamps. The switchboard was arranged to permit of the dynamos running in parallel, or separately with part load each, or either dynamo to run alone with as many lamps as it would carry. Mr. Rawlings was assisted in carring out the installation by Mr. T. Pierce and Mr. A. Clark.

Dover.—At the quarterly meeting of the Finance Committee of the Town Council, the Surveyor said that the cost of the work done by the Board's men for the electric lighting company was £72. 8s. 10d. and £7. 4s. 10d., 10 per cent., for superintendence, and an order was given for the account to be sent to the company. The Chairman remarked that he was anxious to know whether the Town Hall paid or not, and he would like returns showing the differences in the gas lighting of the hall for three months and electric lighting for a similar period. The Surveyor said there were two meters, but it would be difficult to make the comparison, as only the new hall was to be lighted by electricity. The Chairman said it would be near enough for him if he had the three months for the whole buildings. The electric light should be charged for with the charges for the hall. The Town Clerk intimated that he could get the returns.

Newcastle.—An electric motor is in use in the workshop attached to the Grainger-street establishment of Messrs. Reid and Sons, silversmiths. There it is made to operate the lathes, polishers, and gravers used in the manufacture of gold and silver articles. This work it not only does in the most satisfactory way, but it saves time and labour, and Messrs. Reid and Sons are so satisfied with the result of their Grainger-street experiments that they have resolved to adopt electric motors for their manufacturing operations in Grey-street. A special committee of the Newcastle Corporation met on Tuesday relative to the Corporation undertaking the provision of electricity. After some discussion it was resolved to report to the City Council that it would be desirable for the Corporation to be in a position to supply the city with the electric light. They further decided to ask the Council for a certain sum of money—namely, £200—for the purpose of engaging an expert to enquire into the various systems of electricity in the country, and present a report on the same.

Acton.—The Works Committee of the Local Board reported at a meeting last week that as neither Mr. Medhurst nor his representative attended before them, as promised, they considered that the negotiations as to the electric lighting agreement were at an end. The Chairman remarked that the terms of the proposed agreement were such that Mr. Medhurst could not float a company to take over the electric lighting order from the Board; the Board, the Chairman added, could not sell their order to Mr. Medhurst as a private individual. He hoped some other contractor would come forward and take up the work. Mr. Rome suggested that other contractors should be invited to forward their terms. The Chairman thought it would be better to wait for offers. Mr. Lewsey suggested advertising for tenders for the sale of the order. In reply to questions, the clerk said Mr. Medhurst had no claim upon the Board; the negotiations with him were quite at an end. The Board resolved to advertise for tenders for the transfer of the electric lighting order for Acton.

West Coast of America Telegraph Company.—The seventeenth ordinary general meeting of the West Coast of America Telegraph Company, Limited, was held on Tuesday, Mr. J. Denison Pender presiding. In moving the adoption of the report the Chairman stated that the gross receipts during 1893 were £7,122 less than in the previous year. In 1892 however, the income included £4,728 received from the Chilian Government as compensation for the time the Company was closed up during the war; and, again, in that year the rates of exchange in both Peru and Chili were much more favourable than they had since been. The sterling value of the telegrams transmitted last year was £13,155 odd, against £14,800 in 1892, showing a reduction of £1 677, this being entirely attributable to the decline in the rate of exchange; the actual

Digitized by Google

number of words transmitted in 1893 was 131,700 in excess of 1892, so that had the exchange remained the same they would have had a considerably increased revenue. The land line between Buenos Ayres and Valparaiso, constructed by the Pacific and European Telegraph Company, was opened for traffic on March 19 last. The completion of the line restored the direct service between the Company's stations and Europe *vid* Madeira. The service was giving thorough satisfaction to the users of the line, and he was pleased to state that the revenue already received was exceedingly satisfactory. Mr. F. Walters seconded the resolution, which was carried.

The County Council and Electric Lighting.—The Highways Committee of the County Council reported to the latter on Tuesday, in connection with the preparations of the plans, estimates, etc., for the electric light installation for the Victoria-embankment, that the Council on May 8 authorised the retention for a further period of three months of the services of a temporary assistant in the engineer's department. In the committee's report presented on that date the salary of the assistant was wrongly stated to be £3. 3s., whereas £3. 13s. 6d. was the right amount. The committee recommended that the resolution of the Council, relative to the salary of the temporary assistant referred to, be amended by the substitution of the sum of £3. 13s. 6d. for that of £3. 3s. The committee also reported that the House-to-House Electric Light Supply Company had given notice of intention to construct two transformer street boxes at Collingham-gardens. The particulars furnished by the company are insufficient, and it has been asked to supply further details. The committee have sanctioned the laying, by the same company, of mains on the west side of Roland-gardens. The Charing Cross and Strand Electricity Supply Corporation are about to lay mains on the west side of Exeter-street; the Westminster Electric Supply Corporation, on the west side of and across Allington-street; and the Kensington and Knightsbridge Electric Lighting Company of mains along and across New-street, Brompton-road.

The Projected Tramway at Howth.—A public meeting has been held in the St. Lawrence Hotel, Howth, to protest against the tramway which it is proposed to run from Dollymount to the top of the hill of Howth. The chair was taken by the Hon. Judge Boyd, who said they were all aware of the object which had brought them together. The Rev. Mr. Mahaffy would propose a resolution and state the grounds on which they were opposed to the tramway. Rev. Prof. Mahaffy then moved the following resolution: "That the proposed tramway is unnecessary, there being already a convenient train service from Howth to Dublin, and constant communication with the upper hill by long car during the summer months, and by cars and other vehicles at all times. It will prove injurious by disfiguring the scenery, making the roads dangerous, preventing the free passage from one part of the hill to another, and disturbing the peaceful beauty which constitutes the chief attraction of the hill, whether to residents or occasional visitors." He said he did not think it was in the view of the promoters to propose a separate tram line to any part of the way. The better class of people would, he thought, avoid the hill if the tramway was allowed. Mr. Jameson, in seconding the motion, said that the proposed tramway would spoil the appearance of the hill. The motion was adopted. Mr. Culverwell proposed that a committee should be appointed to employ counsel and take other steps on behalf of the inhabitants of Howth to oppose the scheme before the Privy Council. Mr. Maxwell seconded the motion, which was adopted.

The Dover Central Station.—In our last issue reference was made to this station, and we will now amplify our remarks. The plant, which will be laid down at the station by the Brush Electrical Engineering Company for the Dover Company, will be on the alternate-current transformer system. In the boiler-house will be placed three Babcock and Wilcox water-tube boilers. The engines, of which there will be four, will be Raworth's compound vertical inverted type. Two of these engines will be of 175 i.h.p. each; one is 138 i.h.p., and one 84 i.h.p., giving a total of 572 h.p. There will be four alternators mounted on the same bed-plates with the four engines, and connected by flexible couplings, dispensing with the necessity for belting and pulleys. These machines will be of the Mordey-Victoria type Two of these will each be capable of maintaining about 3,400 8-c.p. incandescent lamps. One will maintain 2,600 such lamps, and one 1,700, giving at the commencement provision for 11,000 lamps. There will also be two continuous-current dynamos, each connected with vertical engines, to supply the exciting current to the alternators. Amongst the appliances of the engine-house will be a 15-ton travelling crane for overhauling the machinery, a one-ton portable jib, which can be affixed to any iron pillar in the building, and a four-ton crab. There will also be hydraulic jacks and weighing-machines. The cables will be laid in 2in. cast iron pipes under the roads or pavements. The pressure of the current from the machines will be 2,000 volts, at which the current will be conveyed through the main cables to the transformer stations, where the pressure will be reduced from 2,000 volts to 100 volts, at which it will be supplied to the consumers. The transformers will have a total capacity of 318 kilowatts, and will be capable of maintaining over 10,000 8-candle incandescent lamps. The mode of illumination to be used is two-fold—arc lamps in those parts of the public promenades and main streets which the company has entered into a contract with the Town Council to supply, and incandescent lamps for private lighting. The provision in the contract is for 25 arc lamps of 2,000 c.p.; 16 of these will be set up on the sea-front. The current for these lamps will not be run through the transformers used for converting the consumers' supply, but will be delivered at 2,000 volts pressure at the lamp-post, each lamp having its own transformer. The other arc lamps not used on the sea-front will be placed at intervals along the main thoroughfares.

Electric Lighting for Trains.—We quote the following from the *Railway News*: "Two sets of statements, contradictory to one another, have recently been circulated with reference to the working of the electric lighting system on the trains of the Brighton Railway. On the one hand, it has been alleged that the company's recent experience of this system has been extremely favourable, proving it to be more serviceable and less expensive than lighting by gas. On the other hand, it is said that the company have decided not to extend the electric lighting, but to erect instead extensive works for oil-gas manufacture. We are in a position to state that neither of these statements is strictly accurate, though both contain a modicum of truth It is quite true that the Brighton directors have decided upon the erection of oil gasworks under the Pintsch system both at New Cross and at Brighton, but at the same time they have sanctioned the equipment of eight new trains with electric lighting plant. It seems that the company are engaged in thoroughly overhauling their train-lighting arrangements, but not having formed a decided preference to either system, have resolved to extend both. With regard to the general question of the suitability of electricity for train-lighting, this much seems certain, that in spite of a trial extending over nearly 10 years on the Brighton line, and experiments by the Great Northern, Midland, and other companies, no system yet introduced has thoroughly proved its capacity to meet all the requirements of railway carriage illumination. The Brighton trains cost £400 each to equip, and last year the working expenses for maintenance and renewals were £62 per train. The working cost of new trains, however, will not be so great, because the same number of men already employed to meet the trains and overhaul the apparatus will suffice for a considerable addition to the stock."

The Elmore Companies.—In the course of an article on these companies, the *Financial News* says: "A good many of our correspondents are anxious to know something about the present position of Elmore's Patent Copper Depositing Company. There has been a creeping up in the price of the shares, and holders are naturally desirous of learning to what cause the improvement is due. We should be very glad if we could give them any positive enlightenment; but these shares have on so many previous occasions been made the counters of stock-jobbing transactions, and have been so profitably manipulated by certain financial cliques, that it behoves one to be extremely careful in formulating an opinion without the aid of definite information. One thing is apparent—the rise in Elmore's is not a spontaneous affair. It has been set in motion by somebody, and for some purpose. It is due either to a rig, got up with the object of unloading later on, or to genuine buying on the part of insiders who know of some favourable feature so far not communicated to the general body of the shareholders. During four years the shareholders have watched and waited, now buoyed up with extravagant hopes, now plunged into inconsolable despair. It would, indeed, be a gleam of sunshine worth greeting if Elmore's could, after so many trials, establish itself on a sound paying basis. The progressive character of the business may possibly justify the higher price now quoted for the shares; but we should like some incontrovertible evidence of it before we recommend anyone to buy. Even if the improvement in the prospects warrants a revival of hope, there is a good deal in the financial position that is calculated to check unreasonable expectations. The called-up capital stood, at the end of last year, at £182,390 in ordinary and £17,220 in cumulative preference shares, the latter having been converted from unissued ordinary shares about 12 months ago. In November it was pointed out to the shareholders, and they thoroughly agreed, that as the working capital had been brought down to £4,000—which was obviously inadequate to the requirements of a business which might have to purchase considerable quantities of copper—it was desirable to issue £10,000 of 6 per cent. debentures. Whether the whole of these have been placed or not we do not know; but if not, they, no doubt, will be in the course of time. It will be seen that there are some considerable prior charges to be met annually before the ordinary shares can come in for a dividend, and it must not be forgotten that at June 30 last, when the latest available accounts were made up, there was a debit balance of £21,518, £13,655 of which was loss incurred during the year. There is another point to be looked at in estimating the future value of the shares. Although no action has yet been taken in the matter, it is not improbable that the ordinary capital will be written down to meet the loss incurred in the experimental stages, and by the depreciation in the £12,000 (cost value) of the Wire Company's shares which the Copper Depositing Company holds This reduction was admitted in the 1893 report to be necessary, and although deferred, it may yet have to be carried out, not only as a matter of sound finance, but in the ultimate interests of the shareholders themselves. The fortunes of the other Elmore companies depend more or less on the fate of the one under consideration. The French company, after a huge expenditure and great loss of the shareholders, has gone into liquidation, been reconstructed by a group of French financiers, and possesses no longer anything more than a remote interest for English investors, except those who are directly connected with it, and who may, at some future day, receive back something in the way of dividends if the reconstructed venture manages to score a success. The disastrous collapse of this company, and the only less conspicuous suspended animation of the Austro-German and American promotions, have taken away the occupation of the Foreign and Colonial Company, which existed for the sale of the foreign patents. Whether it will ever

Digitized by Google

have occasion to resume its avocations depends entirely upon the future of those Elmore undertakings which are actually at work. It can scarcely be said by any but the most optimistic believer in the process that it has, as a commercial venture, even yet passed completely out of the experimental stage." With regard to this article Mr. J. Shurmur, secretary to the companies, writes as follows: "Referring to your article to-day on this subject, the Wire Company is not suspended pending the raising of more capital. That was our position some months ago, but since then we have allotted over £30,000 of preference shares, and, in addition, our bankers will always finance our copper requirements up to £25,000, which, together, gives us a very substantial working capital at our disposal to-day. Our splendid freehold works and plant, capable of turning out 50 tons a week of unequalled product, were long since paid for to the last penny. The Board has been reconstituted, and the name of our new chairman—Mr. Edward Reynolds, of Sheffield, who is by far the largest shareholder—is a practical guarantee of success. Our sales agents assure us they can readily dispose of four to five times the present possible output at most remunerative prices, and it is now only a question of days before every tank will be fully at work earning a handsome dividend from the first day they start. All our difficulties have vanished. We are to-day closing the London office and concentrating at the works, where I shall always be pleased to see you or any of our shareholders. The present rise is most certainly not a rig; but is, to my knowledge, chiefly due to buying by the customers of the Copper Company, and by the shareholders eager to recoup previous losses."

PROVISIONAL PATENTS, 1894.

MAY 21.

9862. **Improvements in batteries.** William Morison, 29, Broadway, New York, U.S.A. (Complete specification.)

MAY 22.

9896. **Improvements in the arrangement of gearing for electrically-propelled vehicles, cars, yachts, and launches.** George Walter Leech, 49, Great Eastern-street, London.

9909. **Improved shade-carrier for gas and electric shades.** Edward William Lancaster, 52, Bristol-road, Birmingham.

9927. **Improvements in electrical switches and connecting to the same.** Edward Jesse Piper, 34, Victoria-street, Westminster.

9930. **Improvements in signalling on railways, and means therefor.** The Automatic Electric Railway Signal Company, Limited, Edwin Blakey, and John Patrick O'Donnell, 78, Fleet-street, London.

9949. **Improvements in electrolytic apparatus.** Thomas Craney, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

9967. **Improvements in electric arc lighting.** Charles Aubrey Day, 321, High Holborn, London. (The Higham Electric Company, United States.) (Complete specification.)

9968. **Improvements in the method of and apparatus for arresting motion of electrically-propelled mechanisms.** Elmer Ambrose Sperry, 321, High Holborn, London. (Complete specification.)

9974. **Improvements in or relating to apparatus for heating metals electrically.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

9975. **Improvements in the method of and apparatus for heating, welding, or working metals by electricity.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

MAY 23.

9999. **Improved holder for incandescent lamps.** William McGeoch, jun., and Alexander William Stewart, 154, St. Vincent-street, Glasgow.

10018. **Improvements in electroliers or lamps of the kind chiefly employed and known as extension or floor lamps but applicable to other lamps** William Soutter, 3, Cherry-street, Birmingham.

10021. **Improvements in connection with primary batteries and portable electric lamps.** Samuel William Maquay, 55, Chancery lane, London.

10032. **Improvements in and connected with electrolysis and in apparatus connected thereto.** Emile Gautier, 77, Chancery-lane, London.

10044. **An improved system of producing luminous electric changeable writing and in apparatus therefor.** Alfonso Theodoli, 323, High Holborn, London. (Complete specification.)

10045. **An improved method of and apparatus for controlling the action of electric motors and other prime movers.** John Becher Ormsby and George Henry Banister, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 24.

10115. **Improvements in electric lamps for surgical purposes.** Alfred Charles Cossor, 21, Finsbury-pavement, London.

10101. **An improved gripping tool for electric light and other fittings.** Gustav Binswanger and William Everett Gibson, 73, St. Stephen's-road, Upton Park, London.

10114. **An improvement in incandescence electric lamps.** Bennett Pell, 28, Southampton-buildings, Chancery-lane, London.

MAY 25.

10132. **Automatic zero reading electrical instruments.** Joseph Edmondson, Penny Bank-chambers, Halifax.

10140. **Improvements in regulators for electric currents.** Wilson Hartnell, 9, Old Bank-chambers, Park-row, Leeds.

10149. **Improved apparatus for supporting electrical conductors and the like.** John Orme, 21, Finsbury-pavement, London.

10169. **Improvements in plates for secondary voltaic batteries.** Georges Réné Blot, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

10171. **Improvements relating to writing telegraphs.** Philip Arthur Newton, 6, Bream's-buildings, Chancery-lane, London. (Elisha Gray, United States.)

10172. **Improvements in or connected with vehicles for electric railways or tramways.** Edward Hopkinson, 47, Lincoln's-inn-fields, London.

10186. **Self-locking cleats for electric wires.** Elias Nashold, 323, High Holborn, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1893.

3210.* **Primary batteries.** Maquay. (Amended specification.)

9397. **Electromotors, etc.** Garrard and Blumfield.

10993. **Electric search-light.** Sciama.

12139. **Electric machines and transformers.** Hutin and Leblanc.

12314. **Electrically illuminated signs.** Fricker.

12702. **Electric cables.** Hardingham. (Felten and Guilleaume.)

12850. **Counter of electricity.** Brocq.

13340. **Electric furnaces.** Lake. (Girard and another.)

23902. **Electric motors.** Hall.

1894.

2866. **Dynamo-electric machines.** Wise. (Lewis.)

3108. **Electric railways.** Leffler and Corrigan.

5474. **Electric arc lamps.** Davy.

5816. **Electrical measuring instruments.** Lake. (Weston.)

NOTES.

Pfalz.—Bergzabern, Erlenbach, and Bundenthal are to be connected telephonically.

Sheet Lightning.—A new definition of sheet lightning is a harmless method of misrepresentation.

Derby Electrical Exhibition.—This exhibition has been so successful that it is being continued throughout this week.

Pas-de-Calais.—A proposal is under the consideration of the Municipal Council of Auchel for the introduction of electric lighting.

What Next!—It is reported that an electrical man, singing songs, is walking about the streets of New York. He can do 16 miles an hour.

Greifswald.—An urban telephone system is to be established here. It will be connected with the Stettin, Anklam, and Stralsund systems.

Toulon.—The local gas company, who three years ago undertook the supply of electric light, finds that the use of the latter is profitably developing.

Electric Miners' Lamps.—At Woodyet Pit, Denny, Scotland, where a fatal explosion took place last year, year, electric miners' lamps are now employed.

Liverpool Engineering Society.—The members of this society will visit on July 13 the hydraulic power and electric lighting stations of the Manchester Corporation.

Neuminstor.—A central electric light station is to be established here by private enterprise, and many business firms have already declared their intention of taking current.

Nuremberg.—The question of the erection of a municipal electric lighting station is now so far advanced that circulars have been issued to ascertain the probable demand.

The Gas Institute.—A paper on "Gas and Electric Lighting at Blackpool," by Mr. Wm. Chew, of Blackpool, will be read at the annual meeting of the Gas Institute next week.

Appointment.—Mr. Ross, assistant engineer in the office of the Commission of Sewers, was on Tuesday appointed by the Commission as chief engineer, at a salary of £900 a year.

Reduction in Price.—The Kensington and Knightsbridge Electric Lighting Company notify that on and after the 1st prox. the charge for current will be reduced from 8d. to 6d. per unit.

Obituary.—Mr. T. Eccleston Gibb, the vestry clerk of St. Pancras, died on Wednesday at Kentish Town. He was prominently connected with the carrying out of the electric lighting of St. Pancras.

Loyton.—A committee of the House of Commons on Tuesday passed a Bill confirming a provisional order authorising the Leyton Local Board to light the area within its jurisdiction with the electric light.

The Baltic Canal.—For the electric lighting of this canal, to which reference has been made in previous issues, 23 tenders were received. The contract has been obtained by the Helios Company, of Cologne and Ehrenfeld.

The Westminster Electric Supply Corporation. The employés of this Corporation have started a cricket club, and for the remainder of the season they will play at Raynes Park. Mr. W. A. Pearman is the hon. secretary.

The Fulmen Accumulator.—This type of secondary battery is now being exploited in France by a company with offices at 39, Rue de l'Arcade, Paris. These accumulators are intended both for lighting and for traction purposes.

The Hermite System.—A pamphlet has been issued by Messrs. Paterson and Cooper giving opinions of experts on the Hermite electrical sanitation process. It consists of extracts from scientific reports on the method by bacteriologists and chemists.

A Powerful Search-Light.—A Reuter's telegram says that a great search-light constructed in France which was exhibited at the Chicago World's Fair has been erected at Sandy Hook, New York, and was lit for the first time this week. It is of 194,000,000 c.p.

Strassburg.—We have previously referred to Herr von Miller's plans for an electric lighting station for this city. The Municipality now invite tenders by the 15th inst. for the erection and working of a station based on these plans. The work is to be carried out within a year.

London Electric Railways.—The following private Bills were read a second time in the House of Lords on Tuesday: the Central London Railway (Extension of Time) Bill, and the Charing Cross, Euston, and Hampstead Railway Bill. These Bills will pass unopposed through the House of Lords.

Tramways in Cairo.—The Khedivial Government, through the Minister of Public Works, announces an extension of time for receiving bids for the proposed concession for constructing and working a system of tramways in Cairo and environs. The date for receiving offers has been extended to August 1 next.

Londonderry.—The City Corporation have taken over the electric light works. The plant has cost £20,000. The mechanical part has been carried out by Messrs. Alexander Brown and Sons, and the electrical by Messrs. Siemens Bros. and Co., Limited. The matter is referred to more fully in another column.

Electric Propulsion on Canals.—An exhibition of plans for a maritime canal between the Bay of Biscay and the Mediterranean was opened in Paris on Wednesday by a society of promoters. Some competitors propose that vessels should be transported by railway or by rolling docks propelled by electricity.

Electric Lights for French Hansoms.—Hansom cabs are about to be introduced in Paris, the Town Council being willing to encourage the enterprise on the following conditions: 1f. fares, no *pourboires*, or obligatory tips, gutta-percha tyres on the wheels, electric light, and right granted to fares to take parcels or valises for nothing.

Demonstration of Electrometric Apparatus.—An exhibition of Mr. Waterhouse's discoveries in connection with electric meters, dynamos, and telegraph instruments will take place to-day (Friday) at three o'clock at the works of the Waterhouse Electrical Manufacturing Company, Limited, 67, Southwark Bridge-road.

Exhibition in Leicester.—A trades and industrial exhibition is announced to be held in the Floral Hall, Leicester, in the autumn, under the auspices of the Trades Exhibition Company. There will be sections for engineering, inventions, construction, sanitary appliances, decorative work, furniture, electricity, arts and sciences, etc.

Popularising the Electric Light.—The Westminster Electric Supply Corporation who have decided, as previously mentioned, to reduce the charge per unit to 4d. for cooking and heating purposes from the 1st prox., are issuing to

Digitized by Google

consumers an illustrated circular setting forth the advantages of electric heating, cooking, and ventilating.

Warnsdorf.—Messrs. Siemens and Halske are moving in the matter of the erection of a central electricity station here. Although a number of factories have their own installations, it is expected that there will be many subscribers. As the gas company's contract will shortly terminate, the promoters hope to be able to get the order to light the streets by electricity.

Private Telephones.—With reference to the note on this subject in our last issue, Mr. Newlands, of the Private Wire and Telephone Installation Company, writes to state that the installation at the *Times* office was put up by the Home Telephone Company, Limited, of which he was manager, and which has recently been absorbed by the National Telephone Company.

The "Electrical Review" v. Harness and Another.—Mr. Justice Hawkins has heard in the Queen's Bench Division the case of Alabaster and another *v.* Harness and another. The action was one for maintenance, the proprietors of the *Electrical Review* alleging that the defendant Harness had maintained an action for libel against them. His lordship reserved judgment.

Junior Engineering Society.—A copy of the *Record of Transactions* of the Junior Engineering Society (vol. iii.) for the twelfth session, 1892-93, has reached us. It contains, as frontispiece, portrait of Dr. John Hopkinson, the president of the society, and also portraits of past-presidents. The *Record* is edited by Mr. Walter T. Dunn, the secretary, and is published at 47, Fentiman-road, S.W.

Bradford Technical College.—For the 160 Bradford County Council free scholarships and exhibitions offered in connection with the Bradford Technical College nearly 200 applications have been sent in. The scholarships offered range in value from 10s. for plumbing to £15 for mechanical, civil, and electrical engineering, and are tenable for two years, subject to a favourable report at the end of the first year.

Electroliers, Standards, and Brackets.—A large illustrated wall sheet of new designs of electrical fittings and portable lamps has been issued by the Edison and Swan United Electric Light Company. The sheet shows some very handsome electroliers, brackets, standards, and pendants. Among other fittings may be mentioned hanging lamps, portable lamps, and ceiling fixtures. This sheet will prove handy for contractors.

All Rights Reserved.—We have always been under the impression that a paper read before any particular society became the property of that society. Possibly we may be under a misapprehension, as the *Building News* of the 1st inst. reproduces, with the words "All rights reserved," a paper presented to the Clerk of Works Association, Carpenters' Hall, by Mr. Henry F. Joel, on "Electricity as Applied to the Lighting of Buildings."

The Underground Railway.—In the House of Commons on Monday Mr. Weir put some questions to the President of the Board of Trade with respect to the ventilation of the Metropolitan Railway Company's line. He also wanted to know if the President would enquire whether electric traction might not be introduced, to which Mr. Bryce replied that everybody knew that it was a matter that could be avoided if electric traction were adopted.

Telephony in Austria.—Herr Ritter von Obentrant has given some information with respect to the intentions of the Austrian Government with respect to telephony. It is proposed to establish telephonic communication between Vienna and Berlin, and in addition there will be a telephonic extension westwards to Linz, and a connection between the towns of Brünn and Olmütz. This last line will be connected with the Silesian telephone network.

A Three-Filament Incandescent Lamp.—Messrs. Bartzsch and Co., 11, Stephenstrasse, Berlin, have patented an incandescent lamp in which there are three filaments, so that either 5 c.p., 10 c.p., or 20 c.p. can be obtained respectively, or any combinations of these powers. The socket of the lamp contains a switching apparatus, which allows of any or all of the filaments being switched on. It is, however, difficult to see the practical utility of this lamp.

Laying of New Mains.—The Woolwich District Electric Light Company intend to lay a short length of main in High-street, Woolwich. The House-to-House Electric Light Supply Company are about to lay mains and construct street boxes in Longridge-road, north side, between Earl's Court-road and Templeton-place; and the Kensington and Knightsbridge Electric Lighting Company propose to place underground mains in Albert-place and Douro-place, Victoria-road.

New South Wales.—We have received a copy of the annual report of the works carried out by the Department of Public Works of the New South Wales Legislative Assembly during 1892. The report mentions that the North Shore cable tramway extension was opened for traffic on July 16, and that the Military-road electric tramway was opened on September 20, the electric plant which was in use on the Randwick-Waverley line having been transferred to this tramway.

Electro-Metallurgy in France.—The report of the Société Electro-Metallurgique Française, of Forges (Isère), shows that the position of the company during 1893 was satisfactory, and that the profits allowed of a dividend of 6 per cent. on the paid-up share capital. The company's works at Praz, near Modane, produce 10cwt. of aluminium daily, and it is expected that those works will shortly utilise the water power which the company have at their disposal, to the extent of 3,000 h.p.

Lighting at Torquay.—In a paper read on Saturday before the Association of Municipal and County Engineers at Torquay, Mr. H. A. Garrett (the borough engineer) stated that the Corporation has had the subject under consideration for several years, and that in 1890 they obtained a provisional order. He has made a preliminary report upon the probable cost of an installation to cover the compulsory area, and the advice of an expert has also been called in. The Corporation has, however, not yet proceeded in the matter.

Electricity in Mining.—Mr. A. H. Stokes, the inspector of mines for the Midland district, states that in mines worked with safety lamps all shots should be fired by electricity and low-tension fuses. The simplicity and certainty of firing by the low-pressure system of electric blasting commends itself to all who have adopted its use. The electric fuse can be safely tested before being taken into the mine, and little fear, he concludes, need be entertained that the operatives will be troubled with mis-shots, and the weight of the firing apparatus need not prevent its general use.

Gas-Engine Plant.—A gas-engine installation has been laid down at Carrignan, in the Ardennes, in which poor or inferior gas is used for the engine. According to the *Génie Civil*, the gas-engine employed is of the MM. Delamare-Debouteville and Malandin type of 60 effective horse-power; the gas producer is of the Buire-Lencauchez class, gasifying small coal, and the consumption is said to be 650 grammes per effective horse-power. The generating station contains the gas-engine and dynamos. There are three dynamos of a total capacity of 35 kilowatts, and

Digitized by Google

these are used either to charge accumulators or to supply current direct for lighting.

Portraits by Telegraph.—A Paris telegram says that M. Bertillon, the inventor of the anthropometrical system adopted by the Paris police, and head of the department in which the system is worked, is endeavouring to revive the use of the Pan-telegraph, an apparatus for the transmission of portraits and sketches by telegraph. The apparatus was tried for the transmission of autograph messages some years ago, but the experiments were discontinued in 1877. M. Bertillon considers that the Pan-telegraph would be of the greatest use in view of the fact that portraits of suspected Anarchists or of criminals are constantly being forwarded by the police of one country to another.

The E.P.S. Pocket Catalogue.—A handy and useful pocket catalogue has been brought out by the Electrical Power Storage Company, Limited, in connection with the employment of E.P.S. cells. Those who are about to use this type of battery will be interested both in the concise instructions given in the booklet for erecting the E.P.S. cells, and in the directions printed therein as to the methods of charging and discharging the batteries, whilst the latter information will also be of value to the youngsters already engaged in some capacity or other in private installations and in central stations. A large amount of data is likewise given concerning the various types of E.P.S. cells, and the table of the cost of renewals of plates should be useful.

A Lesson to a Yaller Dog.—A German friend has been troubled by a yaller dog that used to enter his kitchen and seize any food lying about. To get at the meat in the safe, the dog with his broken teeth would even grip the door handle, turn it, open the door, and march off with his prey. The dog thought he knew a thing or two, but our friend could not stand this from a snarling dog that was always barking and could not bite. So one day he suspended from the ceiling just in front of the safe a tremendously large horseshoe magnet. Nothing happened until the third morning, when on entering the kitchen our friend discovered the dog, which wore a broad metal collar, suspended by the latter from the magnet. Now that yaller dog cannot bark, much less bite, and another lesson like he received that morning will teach him to cease snarling.

Electricity at Gotha.—The new electricity station which has been erected by Messrs. Lahmeyer and Co., of Frankfort-on-the-Maine, has been formally opened. A notable feature is that the station serves for the supply of current to an electric tramway, and also for the supply of current, direct and indirect, for lighting purposes. At the central station two steam-engines, made by the Munich Machinery Company, Limited, drive two high-tension and two low-tension dynamos. The former supply current at 550 volts to the tramway and to a transformer station in the centre of the town. The two low-tension dynamos supply current direct for lighting purposes on the three-wire system. At the transformer station the high tension is reduced to low tension, and employed partly for charging accumulators and partly direct for lighting purposes. There are 3,300 lamps connected, and notice has been given for 700 more.

Lighting of the Embankment.—The London County Council on Tuesday adopted the report of the Highways Committee, who reported that they had approved of the plans, specification, and estimate for the generating station, to be constructed near the Charing Cross Station of the Metropolitan District Railway, for the lighting by electricity of the Victoria-embankment and the Waterloo and Westminster bridges, the amount of the estimate being £5,000. It was important, the committee submitted, that the work should be carried out without delay, and they therefore recommended that, subject to an estimate being submitted to the Council by the Finance Committee, the generating station should be constructed by the Council without the intervention of a contractor; and that the plans, specification, and estimate be referred to the Works Committee for that purpose, with instructions that the work shall be carried out with all possible expedition.

High-Pressure Direct-Current Transmission.—With reference to the article given in our issue of May 25 on "The Transmission of Electrical Energy by High-Pressure Continuous Currents," Mr. O. Görling, of Nuremberg, writes that the proposal of Mr. Schultz comes rather late in the day. Mr. Görling says that several installations of this character have been carried out with complete success, and that Messrs. Schuckert and Co. undertook a power transmission contract at Sigmaringen. In this case there are four primary dynamos of 1,100 volts at the generating station, and four motors at the end of the transmission. Each pair of dynamos is connected in series, giving current at 2,200 volts. The distance separating the primary and the secondary stations is 3·1 miles, and an equalising wire is used. At the secondary station the current is transformed down to 220 volts, and is by means of a battery of accumulators distributed on the three-wire system.

The Institution Conversazione.—The conversazione of the Institution of Electrical Engineers took place on Thursday of last week, Mr. Alexander Siemens (the president) and Mrs. Siemens receiving the guests. Among others present were the following: Sir Frederick Abel, Bart., Prof. W. Grylls Adams, Dr. H. E. Armstrong, Prof. W. E. Ayrton, Sir Benjamin Baker, Sir Frederick Bramwell, Bart., Sir J. Crichton Browne, Mr. R. E. Crompton, Prof. William Crookes, Mr. Latimer Clark, Sir John Evans, Mr. S. Z. de Ferranti, Dr. J. A. Fleming, Prof. G. Carey Foster, Mr. C. Hawkesley, Dr. John Hopkinson, Prof. D. E. Hughes, Sir R. Hunter, Prof. A. B. W. Kennedy, Admiral Kinahan, Prof. O. J. Lodge, Sir Henry Mance, Prof. John Perry, Mr. W. H. Preece, Earl Russell, Sir David Salomons, Bart., Sir E. M. Shaw, Mr. C. E. Spagnoletti, Mr. J. W. Swan, Mr. G. J. Symons, Prof. S. P. Thompson, Mr. John Thornycroft, General C. E. Webber, and Sir H. Trueman Wood.

Electric Shocks.—In a communication to the Paris Academy of Sciences, M. d'Arsonval draws attention to the fact that in cases where persons are subjected to the shock of a powerful electric current, death, as in cases of drowning, is often only apparent. Not long ago, he declares, a workman at Saint-Denis, after having been subjected for several minutes to a current of 4,500 volts, was restored to consciousness in a very short space of time, although for three-quarters of an hour he had been left alone, as it was supposed he was dead. It was a Dr. Laborde who was called in, and who resorted to artificial respiration with complete success. M. d'Arsonval, therefore, considers it is important to bear in mind that persons who have been rendered insensible by electric discharges should be treated like those who are rescued from drowning. He thinks that criminals who are "electrocuted" in America are in reality alive after the shock, although they remain insensible, and die shortly in the absence of restoratives.

A Secondary Battery.—Our contemporary *Cosmos* describes in its issue of the 2nd inst. a new type of secondary battery, but omits to mention the name of the inventor. A watertight wooden box contains a certain

Digitized by Google

number—say, six for instance—of ordinary porous pots, each containing a carbon plate having at its upper end a copper terminal. These pots are filled with chloride of lead, arranged round, and in good contact with, the carbon. Round each pot is placed a cylinder of carbon forming the positive electrode, and being in connection with the others by means of a carbon plate arranged at the bottom of the box. The negative electrodes are in communication by copper connections. The cell is filled with a solution of protochloride of iron (60 per cent.), and the battery is then ready to be charged. Theoretically, the battery should yield a horse-power hour per 3·3 kilogrammes of metal. In practice, our contemporary states that it has obtained 50 ampere-hours per kilogramme of active material.

Promiums Awarded by the Institution of Civil Engineers. — A detailed list of the awards made by the Institution of Civil Engineers for original communications submitted during the past session has been issued. The following awards have been made for papers read and discussed at the ordinary meetings: Telford medals and Telford premiums to Mr. J. H. Greathead, M.I.C.E., and Mr. Francis Fox, M.I.C.E., for their joint paper on "The Liverpool Overhead Railway," and a George Stephenson medal and a Telford premium to Mr. Thomas Parker, M.I.C.E., for his paper on "The Electrical Equipment of the Liverpool Overhead Railway." For papers printed in the *Proceedings* without being discussed, a Watt medal and a Telford premium have been awarded to Mr. Bryan Donkin, M.I.C.E., for his paper entitled "Experiments on the Condensation of Steam in Cylinders of Iron and other Metals," and a Telford premium to Mr. G. Croydon Marks, A.M.I.C.E., for his paper entitled "Cliff Railways."

A Mountain Electric Railway.—A mountain railway has for some time past formed a means of communication between Interlaken and Lauterbrunnen, and this has been extended by carrying a further length from the latter place to Murren *vid* Grütsch. The first section of this railway is a three-rail rack line from Lauterbrunnen to Grütsch, and the second section to Murren is worked by electric cars, the distance being nearly three miles. The track in this case is also formed of three rails, and an electric locomotive hauls either two or three cars, according as may be required. Each locomotive is equipped with two 30-h.p. motors, which receive current from an overhead trolley wire, the supply being provided from a generating station situated three-quarters of a mile distant. The return is formed by the rails. The generating station contains turbines of 150 h.p., the water power being obtained from a neighbouring torrent. The turbines drive direct-current dynamos coupled on the same shaft and yielding 150 amperes at 600 volts. The journey on the electrical section of the line occupies 25 minutes. The French journal *Cosmos* of June 2 gives illustrations of the line.

Definition of Inductance.—The American Institute of Electrical Engineers, in assembly at Philadelphia, have adopted the report of the Committee on Units and Standards. The committee recommended that the definition of the term "inductance" shall be identical with that of the coefficient of self or mutual induction, or L. The report stated that the opinion in regard to the definition of this term had been asked of the national electrical professional bodies of Great Britain, Germany, Austria, and France; that the two former were strongly in favour of defining it as being identical with the coefficient of self-induction; that the Electrotechnischer Verein of Vienna had expressed no opinion, and was indifferent; and that the Société Internationale des Electriciens had expressed the opinion that the word should be defined as a coefficient of induction into an angular velocity. On the motion of Mr. Steinmetz, the word "reactance" was adopted for that quantity in an alternating-current circuit whose square added to the square of the resistance is the square of the impedance—that is, the quantity between brackets in the expression

$$C = \frac{E}{\sqrt{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2}}.$$

Transmission of Power.—An interesting installation of the transmission of power has been completed at the works of MM. Meunier at Noisiel, where the chocolate well known under the former name is manufactured. The chocolate factory, which is erected on the banks of the Marne, is equipped with three turbines of 200 h.p. A little over a mile and a half distant is situated a model farm, where practically everything employed in agricultural operations may be seen. The object of the electrical plant is to utilise a portion of the power of the turbines, and to transmit the electrical energy to the farm for lighting purposes, and for the operation of agricultural appliances. The installation has given good results. The generating station, situated on the bed of the Marne, contains, as already mentioned, three turbines of 200 h.p., provided with vertical shafts, and capable of utilising a fall of water, the height of which varies from 3ft. 4in. to 13ft. 4in., according to the season. These turbines, by means of suitable gearing, all work on to a common horizontal shaft, from which the machinery in the chocolate factory is driven. Arranged on this shaft is a pulley, from which the exciter for the alternator is driven. The exciter is of the two-pole class, giving, at 1,800 revolutions, 15 amperes at 90 volts. The alternator, which is of the Brown type, is actuated from the common shaft. It is a two-phase machine of 75 h.p., having eight poles, and furnishing 165 amperes at 150 volts, at a speed of 600 revolutions. The current is transmitted to the farm in question, and is there utilised for the purposes mentioned.

The Tramways Institute.—Mr. J. G. B. Elliot, the secretary, states that at a conference of the members and associates of the Tramways Institute of Great Britain and Ireland, held in Manchester in April, the president mentioned that an opinion had been expressed that the institute devoted too much time to mechanical traction to the exclusion of other matters of interest. This can scarcely be considered quite correct, as reference to past records will show. He further says that the executive has always been most desirous to receive papers upon all subjects appertaining to tramways interests, and in bringing this question to the notice of tramway men, he urges upon them the desirability of sending a paper upon any subject which they may consider should be fully discussed. Thirty-two companies are already members of the institute, representing 262 miles of line and £4,500,000 of capital; but as the necessity for remedial legislation becomes daily more urgent, and the pressure of proposals to damage tramway property is becoming severe, the council invite the serious consideration of tramway shareholders to the urgent necessity for themselves supporting, not by their moral weight merely, but in the manner indicated below, an institution formed solely for their benefit. It is urged upon all tramway shareholders (1) that they should personally become associates of the institute; (2) that they should, by personal interview or correspondence with the member of Parliament representing their particular constituency, induce him to support an enquiry into the operation of the Tramways Act, with a view to its amendment on the large and important matters which experience has proved require

Digitized by Google

alteration and improvement, and the removal from the companies of the grossly unjust impositions to which they are now subjected; and (3) to resist the attempts constantly being made to depreciate their property.

The Scientific Work of Hertz.—Prof. Oliver Lodge discoursed last Friday before the Royal Institution on the "Scientific Work of Hertz." Prof. Lodge described Hertz, who died only some five months ago in the prime of life, as the founder of an epoch in experimental physics, and said that by his death a distinct gap had been caused in the front rank of scientific investigators. Clerk Maxwell had elaborated the mathematical theory of the propagation of E.M.F. by means of waves in the ether. The great work of Hertz's life was to supply experimental verification of that theory. The first experiment was to illustrate the manner in which electric waves emitted from a primary circuit may be picked up by a suitable secondary circuit. The activity of the secondary circuit was manifested by the sparks which occurred at the spark-gap simultaneously with the discharge of the primary. Hertz noticed the curious fact that these sparks pass more easily if they are exposed to the light of the primary discharge. It has been inferred that the ultra-violet rays are in this case the active part of the light, since the interposition of a sheet of glass, which cuts off the ultra-violet rays, is sufficient to destroy the effect. Light, too, falling on a body negatively charged with electricity, greatly accelerates discharge, but has very little effect if the charge is positive. A piece of wire pressing lightly upon a plate of some oxidisable metal, so as to make a bad electrical contact, constitutes an extremely delicate detector. A Hertzian wave falling on it at once makes the contact good, so that a galvanometer is affected. A "coherer" of this kind was shown to be sensitive to a wave radiated from a small sphere some 20 or 30 yards distant. The lecturer suggested that the eye is an electrical instrument of something the same kind, consisting of some material which (like selenium) becomes a conductor under the influence of light.

Power Transmission by Polyphase Currents.—The Jura-Simplon Railway Company decided some time ago to utilise the water power of the River Suze, about a mile and a quarter from the town of Bienne, for their works at the latter place, and entrusted the installation to Messrs. Lahmeyer, of Frankfort, particulars respecting which are given in *Electricité*. The system of distribution which they adopted was similar to that which they employed at the Bockenheim central station. In this system, high-pressure polyphase current is generated at the primary station and sent over the conductors to the secondary station, where part of it is used direct, without being transformed, for driving polyphase-current motors. The balance is transformed into continuous low-pressure current, distributed in the neighbourhood of the secondary station. Continuous low-pressure current is also supplied in the neighbourhood of the primary station from the dynamos used to excite the polyphase alternators. The primary station is installed in a mill on the banks of the Suze, and water is led to it from the river by a canal, 850 h.p. being available. There are two small turbines of 150 h.p. combined for driving the mill, leaving 700 h.p. available, and only half of this is used for the transmission plant, leaving 350 h.p. still not utilised. The buildings are arranged so that duplicate machinery with another turbine can be put in so as to double the electrical output. The existing turbine for the electrical plant is of 275 h.p., and has been made by Messrs. Rieter, of Winterthur. The two generating dynamos, which are coupled direct to the turbine shaft, produce polyphase current at 80 volts. Two Lahmeyer continuous-current dynamos are driven from the same shaft by belt, and serve to excite the alternators. The high-tension current, after having been stepped up to 1,800 volts, is led from the primary station to the secondary station by six bare wires, forming two lines, which are carried overhead. One of these goes to the repairing shops of the railway company at Bienne, and the other to the railway station. At the sub-station at Bienne the current is transformed by a dynamo-motor to a continuous current of 110 volts. Part of the current is utilised for charging accumulators used for lighting the railway trains, and part for lighting the station and yards. At the shops the current is mainly utilised in driving machine tools. The machinery at the primary station is so simple that it is allowed to run by itself, a man employed at the mill looking in occasionally. The railway company pays the mill proprietor, who owns the works, ·04d. per horse-power hour on the running of the turbine.

Christiania Electricity Works.—The results of the working of this station during 1893 have been published. On January 1, 1893, there were connected 2,560 lamps (or their equivalent) for private lighting, 500 for street-lighting, and 183 for the central station, making a total of 3,243. On January 1, 1894, the numbers had increased to 9,930 for private lighting, the equivalent of 1,050 for motors, 500 for street-lighting, and 183 for the central station, making a total of 11,663. The works have made tests as to the consumption of current by the incandescent lamps—the illuminating power of each at the commencement being 16 c.p.—and the influence of the cost per lamp-hour, which appear in the following table:

Class of Lamp.	Number of lamps tested.	Average life of lamp in hours.	Average illuminating power at end of test.	Average illuminating power.	Effective consumption in watts.
General Electricity Company, of Berlin	23	500	11·2	13·6	44
American Edison	19	450	10·88	13·44	44
Venloo incandescent lamps	30	113	16	16	59·6
The Stockholm Glow Lamps Company	2	785	11	13·5	52

The total production of current in 1893 amounted to 312,211 kilowatts, of which 301,483 kilowatts went into the conductors, the balance of 10,728 kilowatts being lost in the accumulators. Of the current delivered into the conductors there were used: by private consumers for lighting, 193,256 kilowatts; by private consumers for technical purposes, 7,971 kilowatts; for public lighting, 70,328 kilowatts; and by the station itself, 9,861 kilowatts; total, 281,416 kilowatts. Thus, the efficiency of the output of the current delivered from the conductors is 93·3 per cent., and compared with the current produced at the station of 90·1 per cent. Current is delivered to consumers at a pressure of 107 volts. The total consumption of coke was 1,091,690 kilogrammes (1,091 tons). Each kilogramme (2·2lb.) of coke produced 286 watts at the station and 258 watts at the consumers. The average daily consumption in kilowatts was as follows: January, 944; February, 1,026; March, 777; April, 508; May, 295; June, 120; July, 125; August, 360; September, 752; October, 1,242; November, 1,752; and December, 2,053. The accumulators consisted of 138 cells, with a normal capacity of 643 ampere-hours, and a maximum discharge current of 193 amperes. The total efficiency was 74 per cent., or 4 per cent. more than was guaranteed. The income for the first working year was 160,581 crowns, leaving a balance of profit of 42,085 crowns.

PHYSICAL UNITS.

BY MAGNUS MACLEAN, M.A., F.R.S.E.

(All Rights Reserved.)

§ 1. In physical science it is essential to have certain definite units in terms of which results of observation, and physical quantities dealt with generally, can be expressed. The object of the writer of this series of articles is to discuss these physical units, and the inter-relations among them, in an elementary, clear, and concise manner. All physical units may be divided into fundamental units and derived units. That is, a few units are chosen and fixed arbitrarily, so that all other units in physics can be expressed in terms of them; then the former are said to be fundamental units, and the latter to be derived units. Theoretically, any three independent units* are necessary and sufficient, so that the selection of the three fundamental units is one of convenience rather than of necessity. The three fundamental units so chosen are: the unit of length, the unit of mass, and the unit of time.

§ 2. Unfortunately for students in physics, there are two systems of units—the British system and the metric or French system. The latter is so much simpler that experimental results will generally be expressed in metric units (centimetre-gramme-second units, or C.G.S. units). But there are many results which are so well known and so conveniently expressed in British units, that we shall follow the usual custom and give them in British units.

§ 3. The British unit of length is the Imperial yard. It was enacted by Parliament (18 and 19 Vict., c. 72, July 30, 1855) "that the straight line between the centres of the transverse lines in the two gold plugs in the bronze bar deposited in the office of the Exchequer shall be the genuine standard yard at 62deg. F., and if lost it shall be replaced by means of its copies," which are preserved at the Royal Mint, the Royal Society of London, the Royal Observatory at Greenwich, and the new palace at West minster. The unit generally used is a foot, which is a third of a yard.

§ 4. The French unit of length is a metre, and is defined as the distance between the ends of a rod of platinum made by Borda, the rod being at the temperature of melting ice. This length was originally intended, according to the measurements of Delambre and Mechain, to be the ten-millionth part of the earth's meridian passing through Paris. But its definition is really the length of Borda's platinum rod, as above stated. The unit generally used is a centimetre, which is the one-hundredth part of a metre.

§ 5. The British unit of mass is the Imperial pound. It is the weight of a piece of platinum marked "P.S., 1844, 1lb." deposited in the office of the Exchequer, and the Act quoted above states that it "shall be the legal and genuine standard measure of weight, and shall be and be denominated the Imperial standard pound avoirdupois, and shall be deemed to be the only standard measure of weight from which all other weights and other measures having reference to weight shall be derived, computed, and ascertained, and one equal seven-thousandth part of such pound avoirdupois shall be a grain, and five thousand seven hundred and sixty such grains shall be and be deemed to be a pound troy. If at any time hereafter the said Imperial standard pound avoirdupois be lost or in any manner destroyed, defaced, or otherwise injured, the Commissioners of Her Majesty's Treasury may cause the same to be restored by reference to or adoption of any of the copies aforesaid, or such of them as may remain available for that purpose."

§ 6. The French unit of mass is the kilogramme des Archives, and though originally intended to be the mass of a cubic decimetre of distilled water at the temperature of 4deg. C., it is really defined as the mass of a piece of platinum constructed by Borda in accordance with a decree of the French Republic in 1795.

* See a paper by A. W. Rücker, M.A., F.R.S., "On the Suppressed Dimensions of Physical Quantities," *Phil. Mag.*, vol. 27, year 1889, page 104; a paper in the same volume, page 178, by T. H. Blakesley, M.A., M.I.C.E., "On Some Facts Connected with the Systems of Scientific Units of Measurement"; also a paper by W. Williams, "On the Relation of the Dimensions of Physical Quantities to Direction in Space," *Phil. Mag.*, vol. 34, year 1892, page 234. Reference will be made to these and other papers in subsequent articles.

The metric system is decimal; Greek prefixes denoting multiplication, and Latin prefixes denoting division.

1 kilometre	= 1,000 metres.	1 kilogramme	= 1,000 grammes
1 hektometre	= 100 ,,	1 hektogramme	= 100 ,,
1 dekametre	= 10 ,,	1 dekagramme	= 10 ,,
1 metre	= 1 ,,	1 gramme	= 1 gramme
1 decimetre	= $\frac{1}{10}$ metre	1 decigramme	= $\frac{1}{10}$,,
1 centimetre	= $\frac{1}{100}$,,	1 centigramme	= $\frac{1}{100}$,,
1 millimetre	= $\frac{1}{1000}$,,	1 milligramme	= $\frac{1}{1000}$,,

The relations between the British and metric units of length and mass are:

1 yard = 0·9143835 metre.
1 metre = 1·0936331 yards = 39·37079 inches.
1 pound = 0·453593 kilogramme.
1 kilogramme = 2·2046213 pounds.

The following are, however, near enough approximations:

1ft. = 30·48cm.
1lb. = 453·6 grammes.

§ 7. It will be noticed that in the British Act of Parliament the word "weight" is used to signify the quantity of matter within a body, whereas when it is used in its proper scientific sense, it signifies the downward force of gravity on the body. The distinction between weight and mass has been excellently put by Clerk Maxwell in his "Theory of Heat," tenth edition,* page 79, from which I quote: "From these legal definitions it will be seen that what is generally called a standard of weight is a certain piece of platinum—that is, a particular body, the quantity of matter in which is taken and defined by the State to be a pound or a kilogramme.

"The weight strictly so called—that is, the tendency of this body to move downwards—is not invariable, for it depends on the part of the world where it is placed, its weight being greater at the poles than at the equator, and greater at the level of the sea than at the top of a mountain.†

"What is really invariable is the quantity of matter in the body, or what is called in scientific language the mass of the body, and even in commercial transactions what is generally aimed at in weighing goods is to estimate the quantity of matter, and not to determine the force with which they tend downwards.

"In fact, the only occasions in common life in which it is required to estimate weight considered as a force is when we have to determine the strength required to lift or carry things, or when we have to make a structure strong enough to support their weight. In all other cases the word weight must be understood to mean *the quantity of the thing as determined by the process of weighing against 'standard weights.'*

"As a great deal of confusion prevails on this subject in ordinary language, and still greater confusion has been introduced into books on mechanics by the notion that a pound is a certain force, instead of being, as we have seen, a certain piece of platinum, or a piece of any other kind of matter equal in mass to the piece of platinum, I have thought it worth while to spend some time in defining accurately what is meant by a pound and a kilogramme."

§ 8. On Saturday, April 2, 1892, the standard yard measure and the standard pound weight, which for twenty years previously had lain in the wall of the great staircase leading to the Committee corridor of the House of Commons, were taken out for the purpose of comparison with the Imperial yard and pound in common use. The standards were first deposited in the wall in 1853, and this was the third test to which they were subjected. The standard yard, which is a bar of bronze, was enclosed and sealed in an oak box, and the standard pound,

* See also *Nature*, May, 1894, correspondence columns, signed "K," "The Reviewer," "Minchin."

† One pound weight

$$\doteqdot 32{\cdot}17\,(1 - 0{\cdot}00257\cos 2\lambda)\left(1 - \frac{5}{4}\frac{h}{r}\right) \text{ poundals.}$$

Where λ is the latitude of the place of observation;
h is the height above the sea-level; and
r is the radius of the earth—approximately 21×10^6 feet.

One gramme weight

$$\doteqdot 980{\cdot}5\,(1 - 0{\cdot}00257\cos 2\lambda)\left(1 - \frac{5}{4}\frac{h}{r}\right) \text{ dynes.}$$

which is of platinum, was deposited first in a silver-gilt case, next in one of solid bronze, then in a mahogany box, fourthly, in a leaden case, and, lastly, in a mahogany box. The weight is first wrapped in a peculiar kind of Swedish paper, quite free from silica, and therefore not liable to cause friction.

The observer at the end of the test said: "I have finished the comparison of the immured standards with the Imperial standards, and I find that they are in the same condition as when they were deposited in 1872. The comparison has been made within the following limits: the pound has been compared within the ten-thousandth part of a grain, and the yard measure within the one-hundred-thousandth part of an inch."

(To be continued.)

THE MUNICIPAL ELECTRIC LIGHT STATION AT BURTON-ON-TRENT.

The Two B's.

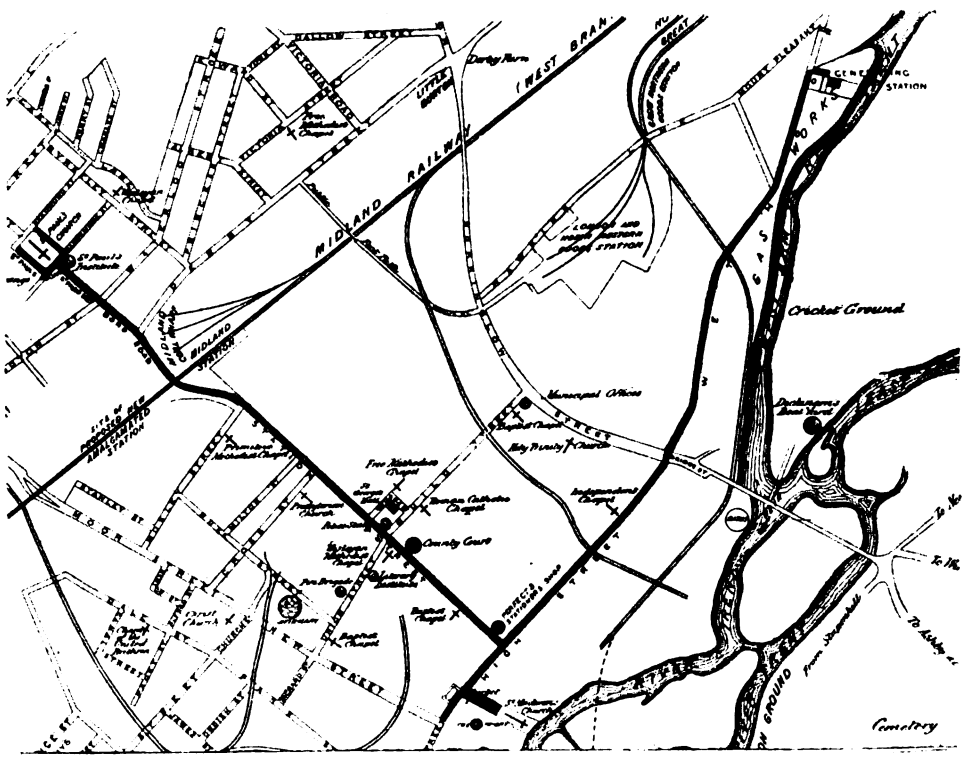
The town of Burton-upon-Trent is something like a four hours' journey by the Midland Railway from the Metropolis. No doubt the 127 miles separating the two would be accomplished in less time were it not for the changing of trains at Leicester, where the traveller has to complete the remainder of the distance by local train stopping at most stations leading on towards Burton. At the same time, a view of the town alone amply repays a visit. Famous for its immense breweries, which form the staple trade of the town, Burton beer and ale have a wide reputation throughout the world. Probably most of the largest brewery firms in the kingdom are located there, the various works being connected by large sidings with the railway, and the traffic being dealt with by tank locomotives owned by the brewers.

The Burton beer is said to be excellent. Our representative had not time to taste it locally on the occasion of his recent visit. He has, however, tried it in town, and found it good—when he got the genuine article. But they go a step further in Burton. They say the beer sold there is superior to that obtainable outside the town, although originating from it. No doubt it is. It must be so, if it is correct, in connection with the sewage-disposal question, that even the rooks and the crows get intoxicated through drinking the liquid sewage. It is a very good thing for the Town Council that the difficulties in regard to the sewage problem are being overcome, otherwise the Council might be summoned for permitting drunkenness on the public highway. It is really no joke for a Burtonite, as our representative was assured frequently happens, when walking out with his best girl and Sunday topper, to feel a sudden bang on his head, his hat crushed in, and hearing an inebriated bird crowing "Bass, Bass," and seeing it flying zigzag down the street.

But the inhabitants are totally different. Many of them, if not the majority, are engaged in the production of beer, and familiarity apparently breeds contempt. There are two decent hotels, the Queen's and the Midland, so you will know where to stop when you pay a visit. The town is in a prosperous condition, and the liberality of the brewers to the town and to their workmen is well known. Well, they can afford to be lavish at times. Mr. Worthington, it seems, has just presented £10,000 to the local infirmary, but more money is wanted. They'll get it—out of beer.

The Dinner to the Corporation.

The reason for these introductory and somewhat discursive remarks is to be found in the completion of the municipal electric light station at Burton by the contractors, Messrs. John Fowler and Co. (Leeds), Limited, who in celebration thereof gave a complimentary dinner last Friday to the Corporation and a number of guests at the St. Paul's New Institute. It was a cheery gathering. There was not a dull moment during the four and a half hours occupied over the dinner and the toast list, the latter being suitably interspersed with music. Messrs. B. Verity and Sons had wired the institute, and fitted up some pretty five-light electroliers and table lamps, which were switched on for the first time that evening.



Burton-on-Trent—Map of District.

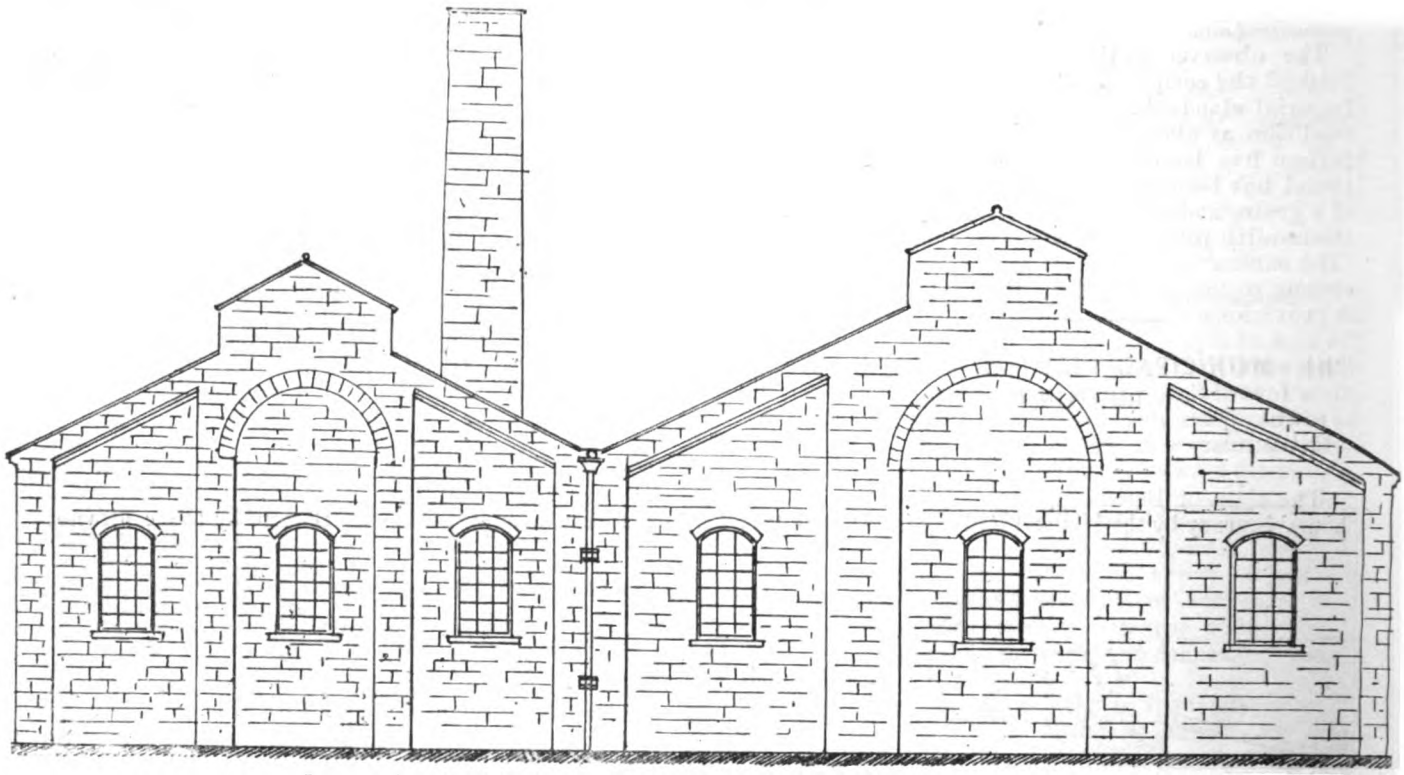
Dinner over—a capital one, by the way—Mr. H. Fowler (the chairman) proposed the toast of "The Queen," which was duly honoured. In toasting the "Mayor and Corporation," he mentioned that the town of Burton was one of the first to obtain a provisional order. When it was granted, a specification was got out, and the result was the station which they had seen that day. The town was extraordinary in combining the gas undertaking with the electric light station. It was the most sensible thing any town could do. It would be difficult to say what the cost of fuel would be in Burton, seeing that that used was almost worthless at the gasworks. The adoption of the

Digitized by Google

electric light would enable the Town Council to pay for many other improvements they had made, and it was due to Mr. Alderman Lowe that the electric light enterprise had reached its present position.

they had some discretion about them because they had selected the same contractors.

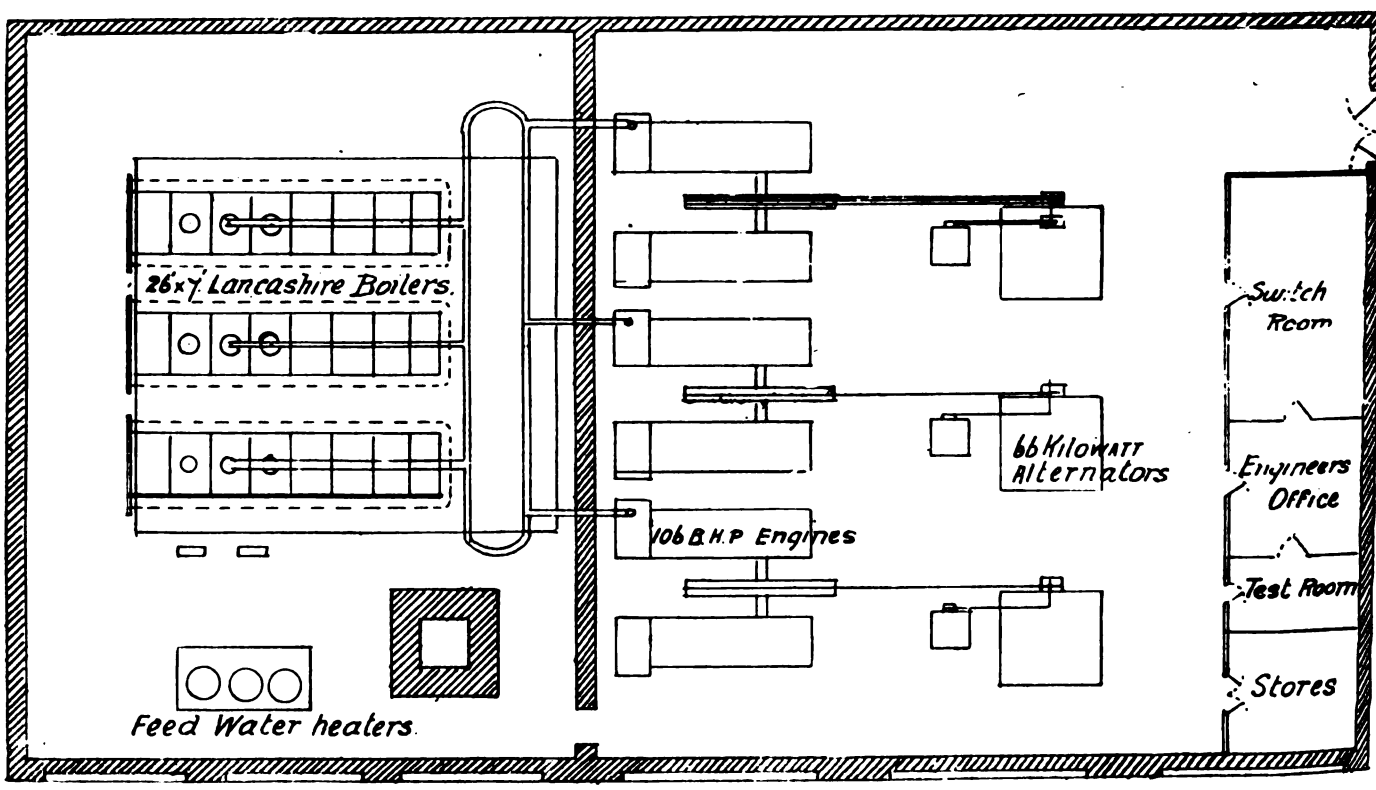
Mr. Councillor MORRIS responded to the toast in some well-chosen remarks.



Burton-on-Trent Central Station—End Elevation of Boiler and Engine Houses, facing roadway.

Mr. Alderman T. B. LOWE (the chairman of the Electric Lighting Committee) responded to the toast in the absence of the Mayor (Mr. Alderman J. A. Coxon) through illness. He said that the Corporation was perfectly free from jobbery, and that he remembered when gas was made first

Mr. Alderman LOWE, in toasting "The Contractors," observed that the Corporation had concluded that their interests would be well placed in their hands, and that the Council were fortunate in having as their engineer Mr. Ramsden, the engineer to the gasworks.



Burton-on-Trent Central Station—Plan of Boiler, Engine, and Dynamo Rooms.

in Burton and sold at 10s. 6d. per thousand. Local self-government was the highest form of government.

The MAYOR OF COVENTRY, in proposing "The Town and Trade of Burton," said that the step taken by the town in adopting the electric light could not fail to assist the trade in the future. They in Coventry were very careful, but

Mr. H. FOWLER, in replying, said that his firm were originally associated with Mr. Hammond in this contract. The latter's present position was entirely due to the satisfactory work he had carried out as a contractor. After they secured the Burton contract, Mr. Hammond withdrew to a higher sphere, that of consulting, and Messrs. Fowlers

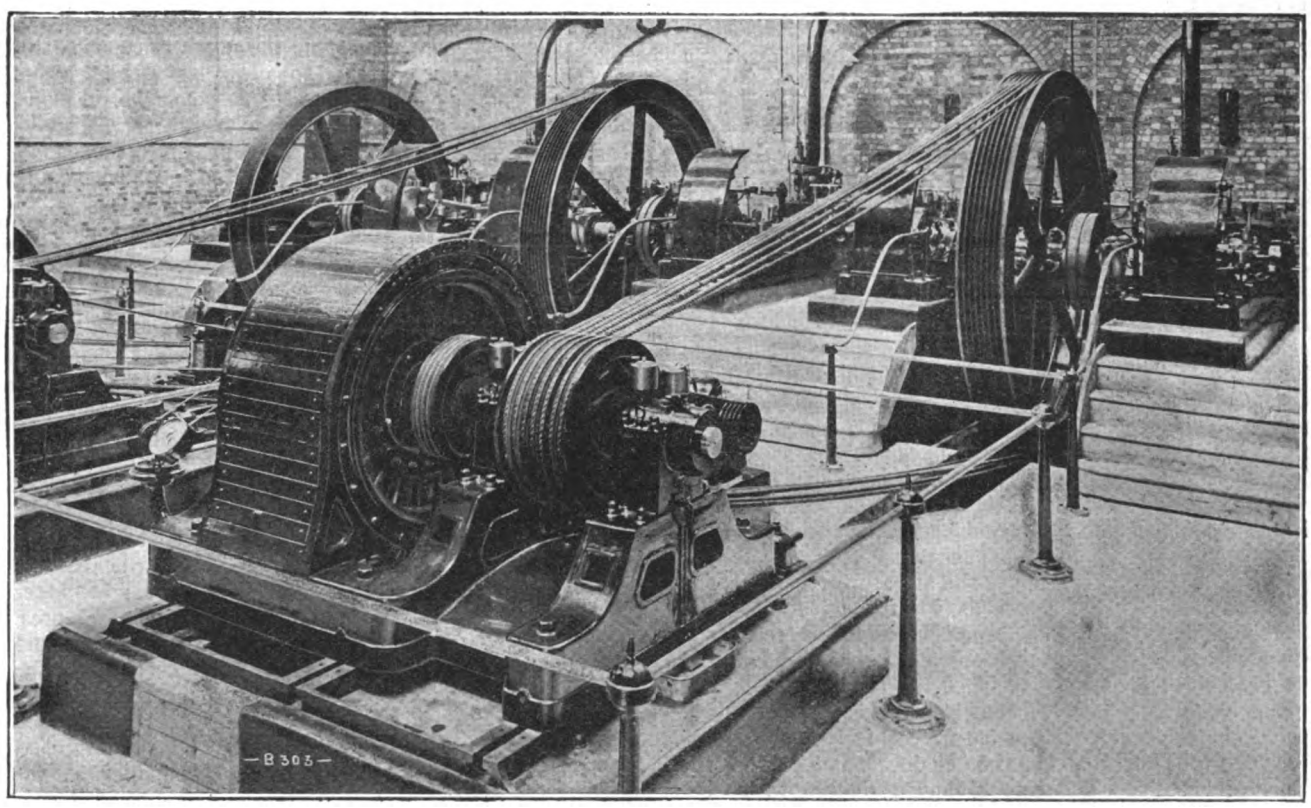
Digitized by Google

remained. That was why the former's name was not coupled with the toast. To Mr. Daniels was due the credit of designing the engines, and Mr. Hall the electrical portion.

The remaining toasts were "Success to Electricity," given by Mr. Alderman HARRISON, and replied to by Mr. HAMMOND; "The Visitors," proposed by Mr. Councillor GRAHAM, and responded to by Colonel HILL; "The Chairman," by Mr. Councillor F. THOMPSON, and replied to by Mr. FOWLER; and "The Engineering Press," by Mr. THOMPSON, and very ably responded to by Mr. W. WORBY BEAUMONT.

GENERAL REMARKS.

The central station, which was inspected by the visitors previous to the dinner taking place, has been erected under the provisional order obtained by the Corporation in 1890. The area of supply included in the order embraces the whole of the municipal borough, but the compulsory order includes only a few of the principal streets in and about the centre of the town. The generating station is situated adjoining the north boundary wall of the gasworks, on a plot of land



Burton-on-Trent Central Station—Internal View of Engine and Dynamo Room.

some three-quarters of an acre in extent, that has been leased by the Corporation from the Marquis of Anglesey for 99 years. The site was selected partly because no very suitable piece of land was obtainable in a more central position, and partly owing to the fact that by having the generating station adjoining the gasworks, working expenses would be somewhat reduced, and great facilities offered for the supply of fuel, removal of ashes, etc. The buildings for the generating station, views of which are annexed, were designed, and the drawings prepared at the gasworks, under the superintendence of Mr. Ramsden, the Corporation gas engineer, who was assisted by Mr. H. Waring. The buildings comprise boiler-house 60ft. long by 45ft. wide by 24ft. high to eaves, and engine-house 60ft. long by 63ft. wide by 24ft. high to eaves. Both of these are substantial plain brick buildings.

The system adopted is the high-pressure (2,000 volts) alternating-current transformer system of supply at constant pressure to transformers fixed in suitable positions in street boxes on the route of the high-tension mains, feeding on to the low-pressure (100 volts) cables for private supply. At present mains are laid and a supply of current is available in the following streets: Wetmore-road, High-street, Market-place, Bank-square, Station-street, Station-bridge, Borough-road, St. Paul's-street, E., and St. Paul's-square, the latter being 3,000 yards distant from the generating station.

THE BOILER-HOUSE.

The boiler-house, the dimensions of which are given above, contains three Lancashire boilers, each 26ft. long by 7ft. diameter, constructed for a working pressure of 100lb. per square inch, with ample space for further boilers when required. The principal feature of the boilers, which are worked under forced draught by means of a separate engine, is the fact that the furnaces are fed practically with the refuse from the gasworks. The fuel comprises a mixture in the proportions of two parts of coke breeze, one of pan ash from the retorts, and one of very small coal. A large portion of these has hitherto been worthless at the gasworks, but now it comes in handy and cheap for the boiler furnaces. The cheapness of the fuel will be readily understood when it is mentioned that it costs less than 3s. a ton, so that considerable economy in fuel is anticipated. Three feed-water heaters are provided for the utilisation of the exhaust steam, whilst the water supply is pumped from a branch of the Trent adjoining the works.

A very simple arrangement of steam, exhaust, auxiliary steam, and drain pipes, including all the requisite pipes to and from the engines, feed-water heaters, pumps, tanks, etc., has been worked out. An auxiliary steam-pipe is provided for supplying the pumps and stoker engine independently of the main steam-pipe. The donkey pumps for feeding the boilers are of the duplex ram type, each of sufficient capacity to feed two boilers when working at their full power. The main steam-pipes are connected up in the form of a ring, to which both boiler and engine branches are connected, thus providing two ways by which the engines can be supplied with steam, so guarding against the possibility of breakdown of the running of the engines, should any portion of the steam range give way or be under repair. These pipes are provided with a suitable number of stop-valves placed between each engine and boiler, and are carried on brackets fixed to the wall of engine-house. The branch pipes to the engines are of wrought iron, fitted with wrought-iron flanges. The exhaust-pipes lead off from under the low-pressure cylinders, and a stop-valve is provided to each engine exhaust to shut it off from the main

Digitized by Google

exhaust-pipe. Valves are arranged so that the whole or part of the exhaust steam can be turned through the heaters or direct into the atmosphere through the roof of the boiler-house.

The Engines.

There are laid down three Fowler 125-h.p. engines, which drive by ropes three 66-kilowatt alternators. The engines are arranged on massive bed-plates raised higher than the floor level. They are of the horizontal, coupled, compound, non-condensing type, the sizes adopted being considered suitable units to work in sections, having regard to the varying load. The speed of the engines is 90 revolutions per minute, and the ordinary working load is 125 i.h.p., at a steam pressure of 95lb. per square inch, but they are capable by increasing the steam pressure of giving a much larger output. The chief dimensions of the engine are: high-pressure cylinder, 14in. diameter; low-pressure cylinder, 24in. diameter; stroke, 24in. Two of the principal features of the engines are the arrangements adopted for collecting the waste oil for re-use, and the vertical governors introduced instead of those of the ordinary horizontal type, the former being much more sensitive than the latter.

The Alternators.

The alternators, which are of the "Leeds and London" type, constructed under Hall's patents, have been specially designed for the distribution of alternating currents from central stations, and they are arranged for parallel running. They are of strong mechanical construction, suitable for continuous running, and capable of withstanding rough usage. The shafts are of mild steel running in gunmetal lined with white-metal bearings of large diameter and ample length; oil throwers and waste-oil chambers are provided at each end of the bearing, from which the waste oil is led into tanks in the base-plate of the alternator. The magnets are the rotating part of the alternator, and consist of laminated horse-shoe stampings built up overlapping (alternately) so as to form a complete circle with polar projections. These are bolted solidly together, and secured to the shaft at the boss by means of keys and set-screws. Magnets so constructed give the maximum efficiency for the energy expended in magnetising them owing to the quality of the iron, and being laminated are quite free from eddy currents, which would cause energy to be dissipated in them if they were solid, due to the armature reaction. The armature being stationary lends itself for sectional construction, and as this is built up of laminated charcoal iron sheets with short polar projections, each section, having its own armature coil securely attached, can readily be removed for inspection or repairs without interfering with any other part of the machine. The armature coil is insulated from the armature core; this is then again insulated from the frame of the machine, thus giving a double insulation between the conductor and frame or earth. The main terminals are mounted upon porcelain insulators, and enclosed in the wood lagging, and this renders it impossible for personal contact with the high-pressure conductors. The alternators are separately excited by small continuous-current dynamos driven back by means of a pulley fixed on the alternator shaft. The low current density at which these machines are constructed will readily permit of their being considerably overloaded with safety during the short period of maximum demand.

The Switch-room.

The switch-room is equipped with the most modern appliances for controlling the circuits and maintaining the voltage on the lamps free from variation. The switch-board is arranged according to the Lowrie-Hall patents, and is similar to that in the West Brompton and other works. It provides in the simplest manner for the putting on and off of either of the circuits and dynamos, either circuit and any dynamo being interchangeable. It is also fitted with a synchronising board, necessary when alternators are run in parallel, or when the load is changed over from one alternator to the other. The plant is, however, designed so that it may be run continuously in parallel. The trenches containing the cables lead into the switch-room at the back of the switchboard, where ample space is provided in which the connections from cables to switches or cross-connections on the switchboard can be easily and safely inspected. The connections at the back of the switchboard are all suitably labelled, so that the attendant in charge has always before him a means of tracing the connections. The switchboard has been designed to deal with two circuits, and is complete with all the necessary instruments for showing current or pressure for switching exciters on or off, and for regulating the voltage so as to preserve a constant potential at the lamp terminals of the consumer. The test-room is equipped with a Thomson standard voltmeter, Siemens dynamometers, a Wheatstone bridge, and a Thomson reflecting galvanometer, etc.

The Distributing System.

The distribution is effected by means of stranded copper single cables, insulated with vulcanised indiarubber and laid in a specially designed system of pipes, combined with service and junction boxes. Each junction-box has a loose cover, held in position by a wrought-iron clamp. The culvert connection from the box to the consumer is made of wrought-iron pipe. The surface boxes are in all cases placed at the corners of the roads, and in the case of a long straight run they are placed at distances of 80 to 100 yards apart. The surface boxes are made in two parts, the bottom part being permanent and the upper part, with the cover, being adjustable, so as to allow its surface to be raised or lowered as the road-level may vary, the lid being filled in with wood, macadam, or pavement, according to the construction of the road. From the surface boxes the cables can be drawn in or out as required. When passing round corners the cable is placed on a revolving drum, which prevents the possibility of abrasion. The jointing of branch cables for consumers' premises is effected by cutting away part of the insulation of the main cable, which consists of indiarubber, in the junction or surface boxes, and soldering the copper conductor to the conductor of the branch cable. The joint is then lapped over with rubber to the full thickness of the original insulation, and vulcanised on the spot, and the cable well taped and mechanically protected. This makes the insulation of the joint practically equal to that of the cable itself.

The transformers are of the Lowrie-Hall type, and were made by Messrs. John Fowler and Co. They are solidly built, are thoroughly insulated in order to avoid any chance of "burning up," and are placed about 220 yards apart in cast-iron waterproof chambers, with side wings or boxes cast upon them, so that the pipes conveying the high-pressure cables at 2,000 volts pass in on one side, and those containing the low-pressure cables, at 100 volts, on the other side, the cables themselves passing through the stuffing-boxes into the watertight chamber. The principle of the stuffing-box is the compression of a substantial vulcanised indiarubber ring of the same quality as the cable itself. In the interior of the box is placed a converter, together with high and low pressure fuses, earthing device, and high and low pressure switches. The latter are double-pole double break, and are connected together by an insulated distance-piece, so that both switches are turned off at the same moment, thus preventing any sparking, whatever load may be switched off. In order to take up any original moisture which may have been in the air and fittings in the box, a jar of caustic potash is placed to absorb this moisture, and once dry it remains so until any future date when the box is reopened.

The capacity of the station is 6,000 8-c.p. lamps fixed, with one set of plant in reserve, but ample space is available for extending the station buildings in one direction, so as to accommodate plant for the electric lighting of practically every house in the town. At present the equivalent of 2,000 8-c.p. lamps is connected to the low-pressure mains, and considering that the supply of current only commenced on 23rd February last, this may be regarded as a fair appreciation of the inhabitants for the electric light. For the moment those people who have not already taken up a supply are waiting until the approach of winter before doing so. It must not be forgotten that the combination of the gas and electricity works on practically the same site and management—Mr. F. L. Ramsden being the borough electrical engineer—is a step in the right direction, and one which is worthy of emulation.

POLYMORPHIC GENERATORS.

M. E. Hospitalier, in a lengthy article in the current issue of *L'Industrie Electrique*, deals with polymorphic generators and transformers of electrical energy. He terms polymorphic generators those machines which can produce successively or simultaneously electrical energy in various forms, and polymorphic transformers those apparatus which receive energy in one form and give it out again in one or several different forms. The author then reviews the principal types of these machines and apparatus, and gives the following classification.

POLYMORPHIC GENERATORS.

Direct and alternating currents	Pixii and Clarke's first machines. Small magnetos and demonstration dynamos Helios dynamo-motor-transformer (1887). E. Thomson's mining dynamo (1890).
Continuous and alternating diphase currents	Schuckert dynamos (1891). Westinghouse dynamo for Rochester (1893). Eclairage Electrique Company's dynamos (1894).
Continuous and alternating triphase currents	Ducretet and Cadiot demonstration dynamo.
Alternating, simple, and diphase currents	Tesla-Westinghouse dynamos (1893). Creusot twin dynamos (1893).
Alternating, simple, and triphase currents	Triphase-current dynamos.

POLYMORPHIC TRANSFORMERS.

Form of current to be transformed.	Form of current as transformed.	Inventors, apparatus, and applications.
Continuous currents	Alternating simple currents	Solignac undulator (1877). Helios transformer (1887). E. Thomson rail welder (1893).
	Alternating diphase currents	Schuckert apparatus (1891).
	Alternating diphase currents	Dolivo-Dobrowolsky apparatus (1891). Hutin and Leblanc apparatus (1893).
Simple alternating currents	Continuous currents	Gaulard commutator (1884). Lane Fox commutator (1887). Pollak commutator (1893). Helios transformer (1887).
	Alternating diphase currents	Two circuits with different self-induction. Tesla (1887 Self-induction and mutual induction. Ferraris (1888). Self-induction and capacity. Boucherot (1890). Hutin and Leblanc (1891). Motor with closed asynchronous armature with secondary inductor coils. Potier (1894).
	Alternating triphase currents.	Motor with closed asynchronous armature with secondary inductor coils. Potier (1894).
Alternating diphase currents	Continuous currents	Schuckert (1891). Budapest central station (1893).
	Simple alternating currents	No special apparatus. Take separate branches from each of the two circuits.
	Alternating triphase currents.	Scott (1894). Two induction transformers.
Alternating triphase currents.	Continuous currents	Lahmeyer's motor-transformer (1893). Hutin and Leblanc (1893).
	Simple alternating currents	No special apparatus.
	Alternating diphase currents.	Scott (1893).

THE VENTILATION OF BUILDINGS BY ELECTRICITY.

The subject of efficiently ventilating public and other buildings is of paramount importance, and has received a certain amount of consideration at the hands of electrical engineers in the introduction of electrically-driven fans. A method applicable to practically every system of ventilation has, however, not hitherto been brought out; but Messrs. Hodges and Todd have now devised a means intended to ventilate buildings by electrically controlling the air-shafts automatically at any desired temperature, and to keep the temperature of rooms constant. It is termed the Westbrooke thermo-electric ventilating apparatus, and a general view of it is given in Fig. 1, and a diagram of connections in Fig. 2. The important features of the apparatus are that it can be easily connected to any existing form of ventilator, and that it is cheap and reliable, and entirely independent of personal supervision.

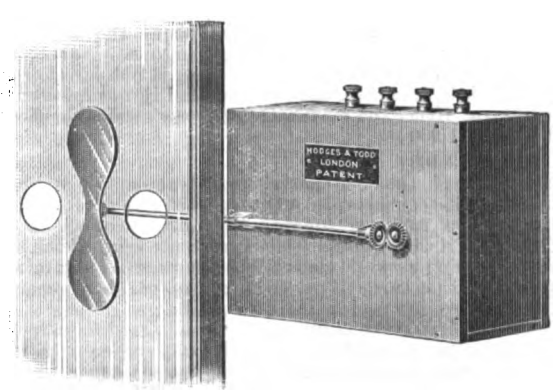

FIG. 1.

As will be seen by the illustration, the apparatus is compact and occupies very little room. It consists of one or more air-valves electrically controlled by means of a thermostat or thermometer adjustable to certain predetermined degrees of heat or cold. The action is as follows: Let us assume that the heat of the building or room is required to be kept, say, between 65deg. and 75deg. F. An electromagnet, M, is placed in circuit with a battery, B, and a revolving drum, D, which is rotated by a strong spring, and makes circuit between the bottom contact, A, and each of the two top contacts, A_2 and A_3, alternately through the thermometer or thermostat. On the temperature rising to 75deg. the contact is made, and the circuit is completed through A_2. The electro-magnet attracts the armature and allows the drum to rotate a quarter of a revolution; this opens the ventilators and cools the room. As soon as the drum begins to revolve, the circuit is broken and the battery is not again put into use until the temperature falls to the 65deg., when contact is again made, and the circuit completed through the other spring, A_3; the drum then rotates and closes the ventilator. This action is repeated every time either limit is reached.

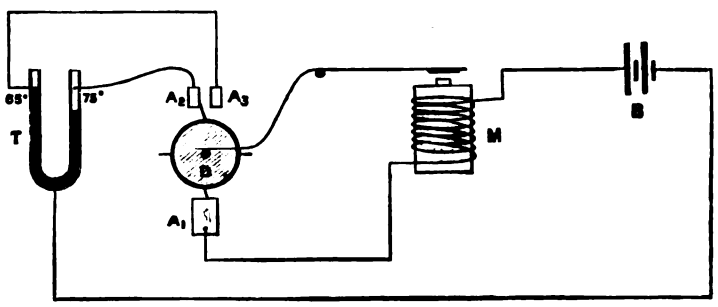

FIG. 2.

Digitized by Google

If used in connection with a thermostat instead of a thermometer, the apparatus can be regulated so as to work with a variation of 2deg. of temperature; and the electrical circuit being only made momentary, a very minute amount of current is used, being considerably less than that required to ring an ordinary electric bell.

This system of ventilation should prove of value for use in hospitals, conservatories, and public buildings where it is necessary to have the temperature kept within certain limits. The apparatus can be fitted to any existing air-shafts. It can also be applied to the working of ventilating fans for starting and stopping at certain temperatures.

SOME REMARKS ON POWER DISTRIBUTION BY ELECTRICITY, WATER, AND GAS.*

BY ED. C. DE SEGUNDO.

For some time past the author has been struck by the great discrepancy between theory and practice that must exist in the working of electric generating plant in central supply stations where steam is used. Observation and experience alike have served to accentuate the inefficiency of electric generating plant, and some rough comparisons made with other modes of producing and distributing power have led him to go into the matter more carefully, and when invited by Mr. Worby Beaumont to contribute a paper to your society, he not only felt honoured at such a request, but was glad of an opportunity of bringing this matter before engineers for discussion. Such a subject as the distribution of power admits of practically endless elaboration. Moreover, nothing can be gained by generalisations from the results of existing or proposed distributing systems. The proper value of each system is entirely conditioned by the initial form in which energy is available, and by the final form in which it is required. As one of the most important developments of modern engineering lies in the application of electrical energy to lighting, this latter will be considered as the final required form of energy, and coal will be taken as the initial form in which energy is available. These conditions apply to nearly all large towns. In the following lines, the author proposes briefly to consider: (1) the efficiency of electric generating plant in central stations at the present day; (2) the efficiency of power-producing plant in hydraulic power stations; (3) the efficiency of gas-engines for production of power.

Efficiency of Central Stations.

The definitions of efficiency are probably more numerous, even, than those of "load-factor," and no doubt the ingenuity of that class of investigator which seeks to make a labour of investigation is not yet exhausted in the direction of finding out new possible ratios; but in such a paper as this, which is designed more to suggest a line for discussion than to deal with any discoveries or startling novelties, it is well to briefly consider which definition of efficiency is best calculated to serve the purpose of this paper. The efficiency with which the practical engineer has to deal may be expressed—perhaps with brutal matter of fact-ness—as the ratio of what you get to what you pay for. But while such definition expresses the main value of a combination of machines commercially, it is not a convenient ratio for comparison with other similar ratios, because the introduction of market value at once destroys the possibility of bringing each fraction to a common denominator. As the motors that will be considered to-night are all heat machines, the author proposes to base his comparisons upon the ratio of the thermal equivalent of useful work available for commercial purposes to the calorific value of the fuel burnt per hour. Such considerations as the cost of fuel can easily be applied after. This definition, however, is open to the objection that it is not fair. It may be argued that if a heat machine of necessity rejects a large proportion of the heat it receives, it is not just to calculate an estimate of efficiency upon a basis which is impossible of realisation, and that the efficiency should be expressed by the ratio of useful work to maximum possible useful work in that class of heat machine. The author would submit that while such a contention bears the semblance of justification, it should be borne in mind (1) that the fact of a machine necessarily rejecting a large proportion of the heat received cannot be pleaded as a valid reason why such a proportion of heat should be rendered unavailable, (2) that the definition adopted by the author gives an absolute basis for comparison, (3) that as long as the meaning attached to the word efficiency is quite clearly understood it can make no difference to the argument if the actual instead of the ratio of the actual to maximum theoretical efficiency is used, (4) that the latter is merely one of the very numerous definitions of efficiency. A steam-engine is usually accounted an extremely wasteful heat machine, but this is, strictly speaking, not the case. The only way to increase the efficiency of the steam-engine is by lowering the lower limit of temperature, but directly efforts are made in this direction a limit is soon reached beyond which further lowering of the temperature not only ceases to be productive of any good, but is productive of evil. In short, it may be said that all the heat developed in the combustion of fuel is utilised by the steam-engine, either in doing work or in providing the means of doing work or controlling the rate at which work is done. The efficiency of the steam engine and boiler combined is not difficult to determine; it is the ratio of the thermal value of the brake horse-power hour to the calorific value of the fuel consumed per brake horse-power hour.

The efficiency of the gas-engine and its equivalent of steam-boiler requires some investigation. A ton of coal, according to Mr. Emerson Dowson, may be taken to produce 9,500 cubic feet of gas and 1,500lb. of coke, of which about 400lb. will be consumed under the retort. Assuming that coal having a calorific value of 14,000 thermal units per pound is used, and taking the calorific value of coke at 10,000 thermal units, the number of thermal units liberated from the ton of coal is (neglecting heat necessary to raise the mass of coal to the temperature of the retort),

$$2,240 \times 14,000 - 1,500 \times 10,000, \text{ or } 16,360,000 \text{ thermal units.}$$

Of the heat developed by the consumption of the coke under the retort, a large proportion can never be expected to reappear in the gas. But 16,360,000 thermal units have actually disappeared in producing 9,500 cubic feet of gas; hence $\frac{16,360,000}{9,500}$, or 1,722 thermal units should be accounted for per cubic foot of gas.

Prof. Kennedy, Prof. Unwin, and others have made calculations of the calorific value of a cubic foot of gas, the results of which agree fairly. The average calorific value of London gas may be taken as 620 thermal units per cubic foot at 55deg. F., and at a pressure of 14·71b. per square inch; hence the efficiency of the gas generator is $\frac{620}{1,722}$ = about 35 per cent.

The function of a steam-boiler is, in the case of a gas-engine, split up into two—one portion is done at the gasworks, and the remainder in the cylinder of the engine itself. Now about 20 per cent. of the heat given to a gas-engine is turned into indicated power, or in the case of a large-sized engine about 20 per cent. is converted into brake horse-power. Hence the real efficiency of the gas-engine and boiler so to speak is about 7 per cent. The efficiency of a non-condensing steam-engine consuming 2lb. of coal of a calorific value of 14,500 thermal units and working at 80 per cent. mechanical efficiency is 8·72 per cent., so that the total efficiency of one machine is very much the same as that of the other on this basis of argument. But Mr. Dowson claims to produce one brake horse-power hour for 1lb. of anthracite, by using his generator gas. This (taking the calorific value of anthracite at 16,000 thermal units per pound) would correspond to a total efficiency of nearly 20 per cent., an efficiency which the steam engine and boiler can never hope to reach. Although the author desires to consider the two heat machines on the basis of what may be termed the useful efficiency—namely, the ratio of available power or brake power to power equivalent of fuel burnt—still, in the face of so great a difference as the foregoing, it may be of interest to enquire into the reason of the difference, and to do this it is necessary to consider another efficiency—namely, the ratio of heat turned into work in the cylinder to the maximum theoretically possible. The latter quality is expressed by Carnot's law as the ratio of the difference of temperature at which heat is received and rejected to the absolute temperature at which the heat is received. In the case of the steam-engine this ratio is not difficult to determine, because the heat is all received at one temperature and rejected at one temperature. But in the case of the gas-engine this is not so. As mentioned before, part of the function of the boiler, or part of the operation of calling into existence the working fluid whereby heat energy may be transformed into mechanical energy, is performed in the cylinder of the engine itself. This operation cannot be instantaneous, in obedience to physical laws: therefore the heat is received during an appreciable interval of time and at temperatures varying from the temperature of the mixture and the end of compression to the maximum temperature reached by the charge after explosion. In some parts of the cylinder this temperature may, according to Mr. Clerk, be as high as 3,400deg. F. It would appear, however, that most authorities agree upon 2,700deg. F., as about the maximum temperature reached by the charge in gas-engines of all forms. The temperature of the discharged products is not far short of 800deg. F., though, of course, the heat rejected is not rejected at one temperature. Hence the maximum efficiency attainable should be $\frac{2,700 - 800}{3,160} = \frac{1,900}{3,160} = 60$ per cent.

The efficiency of the non-condensing steam-engine cylinder under an admission pressure of 130lb. per square inch, and an exhaust pressure of 20lb. per square inch, would be about 18 per cent. Therefore, if this steam-engine turns 8 per cent. of the heat into work, it is doing as well relatively to its peculiar limitations as the gas-engine that turns 26 per cent. of the total heat received into work. The greater useful efficiency of the gas-engine therefore must be ascribed to the nature of the vehicle used for carrying the heat, and not to the superiority of the gas-engine as a heat machine. The great faults of a gas-engine are (1) the enormous heat lost in the cooling effects of the cylinder jackets (sometimes over 50 per cent. of the total heat), and (2) the high temperature of the exhaust products. It is not within the scope of this paper to even suggest any direction in which the efficiency of the gas-engine might be enhanced, but it is obvious that if the link could be forged between the now disconnected heat chain in the gas-engine cycle, whereby the heat carried away in keeping down the temperature of the cylinder could be usefully expended in some other part of the cyle, the time would not be far distant that Sir Frederick Bramwell has spoken of, when all that remains of the steam-engine would be a working model or two in some obscure museum.

Let us now consider an electric generating plant using steam

* Paper read before the Society of Engineers,

Digitized by Google

power. Tests of various portions of electric generating plant are continually being published, which, if they are any criterion of what may be attained in practice, would point to an extremely high efficiency of a generating station as a whole. Any dynamo manufacturer would be much insulted if one were to suggest that his 30-kilowatt machine would not yield a commercial efficiency of over 90 per cent. at anything like full load. The makers of high-speed, non-compound, non-condensing engines claim a mechanical efficiency of something like 90 per cent., with a steam consumption of 18lb. one horse-power hour, or 20lb. per brake horse-power hour, and, moreover, they are always prepare to prove it. Only a few weeks ago Messrs. Siemens published an account of a test of a steam dynamo driven by a Willans engine which resulted in a combined efficiency of 88 per cent. It is also possible to obtain boilers which will evaporate over 12lb. of water from, and at 212deg. F., per pound of good coal. Now, it may be interesting to compare the best possible results based upon such efficiencies. Take a pound of coal whose calorific value is, say, 14,500 thermal units. The author is given to understand that certain boilers in one of the electric generating stations in London evaporate 12·8lb. of water from and at 212deg. per pound of coal. This would correspond to an efficiency of about 75 per cent. Allowing 30 per cent. for loss in transmission and radiation, and 13 per cent. as the highest thermal efficiency of a non-condensing, high-speed steam-engine using 18lb. of water per indicated horse-power hour, this would leave 1,372 thermal units turned into work in the cylinder of the engine. Taking 88 per cent. as the efficiency at which a steam-dynamo was recently described to be capable of working, 1,207 thermal units, or nearly 350 watt-hours, should reappear at the dynamo terminals, and subtracting 10 per cent. for loss in distribution, 315 watt-hours should be paid for by the consumer per pound of coal burnt at the station. This is equivalent to a consumption $\frac{1,000}{350} = 2{\cdot}86$lb. of coal per unit delivered. Were a full load to be maintained at a generating station, this result is what should be realised if the efficiencies claimed for the various factors are trustworthy. But nothing approaching this figure is attained in central-station work, and the whole of the discrepancy is attributable to the influence of a load-factor. In all, eight definitions have been given of the term load-factor. In the considerations under review the author takes the following definition—namely, the ratio of total output to safe maximum output for which the plant is designed. It will be interesting to compare existing practice with the result obtained by assuming efficiencies, etc., which may be reasonably considered to accompany the working of a plant under the ordinary working conditions in England.

In a modern generating station the sizes of the generating units should be so proportioned, and the general arrangements so designed, as to enable a careful man to keep the load on those of his units which are running at a minimum of from 50 to 60 per cent. of full load. This means that on the average the units in work will run at something considerably over half load. From calculations based on the results of actual practice, the author has arrived at 9·5 per cent. as the ratio of thermal equivalent of watts at the dynamo terminals to heat contained in steam supplied which should obtain in a well-regulated central station under ordinary conditions of working in England. Taking, as before, 1lb. of coal of a calorific value of 14,500 thermal units, allowing a boiler efficiency of 70 per cent., 10 per cent. stand-by losses, 9·5 per cent. efficiency of steam dynamo, and 10 per cent. loss in distribution, not more than about 4·4lb. of coal should be consumed per kilowatt-hour, delivered to consumers' terminals. But this figure is not approached in practice, except in one instance by Mr. R. E. Crompton, who states that at Kensington Court he burns 5·5lb. of coal per kilowatt-hour delivered all the year round; but he states that in doing this he forces his boilers, although it is not easy to appreciate the exact meaning of forcing a boiler. Certainly, forcing a boiler usually results in a greater evaporation at a greater consumption per pound of water evaporated, as it is well known that a boiler works most economically at about three-quarter load. Prof. Kennedy has obtained some very good results in the generating stations of the Westminster Electric Supply, but not approaching the figure above arrived at. Mr. Druitt Halpin stated, in the course of some remarks at Nottingham last year, that an analysis of the Board of Trade returns of electric light companies showed an evaporation per pound of coal of only 4lb. of water in the best example and of one or less than one in the worst. This anomaly is difficult to account for; it is usually ascribed to a low load-factor, but this hardly seems reasonable.

Efficiency of Hydraulic Power Stations.

Take, for instance, the working of a station of the London Hydraulic Power Company, The plant consists of boilers, engines, and pumps combined, and accumulators which in practice only act as equalizers. The efficiency of the boilers, the stand-by losses, and the loss by radiation will be about the same as in the case of an electric generating plant—at least, there is no reason why they should be different. But the engines will probably be more economical, because although they run at a diminished speed where the demand on the mains is small, they always work at full load per revolution; of course the engine efficiency is not quite so good at slow speed as at high, but even at a slow speed an engine working at full load per revolution must compare favourably with one doing the same total work in horse-power hours at double or three times the speed. Moreover, at an hydraulic power station it is generally practicable to use triple-expansion condensing engines.

(To be continued.)

THE LONDON CHAMBER OF COMMERCE.

A general meeting of the Electrical Trades Section of this Chamber was held yesterday afternoon at the offices of the Chamber to consider an important and somewhat extensive agenda paper. The proceedings were opened by the chairman of the section, Major Flood Page, who, after the customary routine business, proposed that Mr. Emile Garcke be appointed as chairman of the section during the ensuing two years; this was seconded and carried, a hearty vote of thanks being accorded to Major Flood Page for the valuable services rendered by him to the section during his term of office. Mr. Alexander Siemens was re-elected as deputy chairman, the question of appointing a second such official being left open for the time being. The principal items on the agenda paper dealt with the subjects postponed from the previous meeting, the first being that of road traction. A letter was read from the Board of Trade to the Chamber stating that they had sent on to the Home Office a copy of the letter on this subject addressed by the Chamber to the Board. Major Flood Page informed the section that he had good reason to believe that some difference of opinion existed on the question between the Home Office and the police authorities, and that the action of the latter to some extent appeared precipitate. An application would shortly be made to the police authorities for a license under which an electric vehicle might ply for public hire in the streets, and this would probably lead to a decisive expression from the proper authorities. The section therefore decided to take no immediate action meanwhile, leaving it to the secretary to watch the progress of affairs and at once summon a meeting when necessary, either for considering the question or appointing a small committee for the same purpose in a more convenient fashion. The next question related to the rating of electric supply stations more particularly, and a small committee of five, with power to add to their number, was appointed to consider the somewhat confidential matters involved, and to safeguard as far as possible the interests of supply stations in reference to their assessment for the public rates. The same committee was also requested to consider the position of electric supply stations with regard to alleged nuisances arising therefrom to the public; and although perhaps the real position of these undertakings with reference to actions for damages is based on a legal point—not by any means of unfavourable aspect for the electrical industry—yet it was thought best to refer the matter to this committee as being well qualified to act in the matter from experience of central-station work.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE COST OF ELECTRICAL ENERGY.

Sir,—Until the copy of the *Journal* of the Institution of Electrical Engineers which will contain the (so-called) discussion of Mr. Crompton's paper and his summary of the same is issued, I feel myself debarred from dealing with a subject which, in the interests of the profession, I do not think should be allowed to drop.

Each speaker (including myself) has the opportunity of revising the notes of what he said, and the reader of the paper could not be expected to be able to revise the notes of his own final speech until he has had an opportunity of seeing all those revisions in print.

When the number of the *Journal* containing the information in its latest form is out, I trust you will allow me space to show that my friendly criticisms, especially of Table VI., cannot be dismissed in quite as offhand a manner as that assumed by Mr. Crompton on May 24.—Yours, etc.,

C. E. Webber.

27, Chancery-lane, W.C., June 5, 1894.

Laibach.—A scheme for the electric lighting of the town has been prepared by Messrs. Ganz and Co.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THE PERENNIAL BOILER.

Whenever any engineer who may luxuriate in the membership of one or other of the institutions desires to bring himself prominently forward by creating a lively discussion, not only at the institution meetings, but for weeks afterwards in the editorial and correspondence columns of the technical papers, he has only to advocate through thick and thin the merits and advantages of one particular type of steam-engine, boiler, dynamo, or combination of these. Forthwith an avalanche of praise and abuse is poured upon him, from which he emerges, with luck and skill, to take higher rank than ever. Turning, however, from the person to the things, one gets a little tired of the apparently endless dispute as to this or that appliance being the very best of its kind: of course, a thorough ventilation of opinions may be desirable—so long as it is unbiassed, though that is not very often the case, perhaps—but the absurdity of laying down a hard-and-fast rule whereby to regulate the design, say, of an electric lighting station steam plant should be too obvious to require attention by intelligent men.

Yet the question of absolute superiority in, for instance, boiler design and construction is continually cropping up and being argued, as though the real results could be in any way influenced by mere personal opinions or preferences, however much these may alter the facts when stated. One set of engineers swears by the water-tube type; others can see no good in anything but the Lancashire boiler. Both may be right, just as both are certainly wrong in advocating their particular fancy under all conditions. It is neither fair nor wise to compile a formula of design according to which all electric lighting stations are to be carried out. A boiler has to fulfil many conditions for work of this kind: it must not smoke, or the local authorities will have a voice in the matter; it must be a dry and quick steamer, or—what is the same thing to some extent—it must have a large reserve of steam power for the occasions when a sudden demand for light sometimes makes a difference of hundreds of horse-power in the output of the station. Moreover, it should aim at something more than mere high evaporative efficiency—it must have a low fuel cost per unit of water evaporated.

All these conditions may involve such essentials in a boiler that no single type will fully comply with them, but it is not fair to emphasise such qualities as are possessed by one type in order to give it higher rank than others. If, by putting the necessary qualities on a level, it be found that some are contradictory and impossible of attainment in any one design, then surely the proper plan to pursue is to adopt more than one type—to use, say, both water-tube and Lancashire boilers in any electric lighting station, the exact proportions of either being relatively determined by local conditions, such as cost and quality of fuel, importance of smoke prevention, etc. At present, however, the designing engineer appears to be as a rule too much prejudiced in favour of one type to entertain the idea of using any others.

Digitized by Google

The wordy battle which has arisen on this point from Mr. Crompton's recent paper presented to the Institution of Electrical Engineers brings forcibly to one's mind the admirable suggestion made by *Punch* at the time of the Berlin Conference. That venerable serio-comic represented Lord Beaconsfield (whose wit was more extensive than his knowledge of French) hesitating at the door of the conference rooms, with his hand on the door knob sufficiently long to ask his fellow-plenipotentiary the proper French expression for "compromise."

We suggest the same idea to boiler-makers and boiler-users: by admitting the good points in each there will be found ample scope for development, without choking off one another until tangible results show the foolishness of such a process.

We make another suggestion, too. The makers of both water-tube and Lancashire boilers would do well if they spent time and energy on adapting their appliances for oil-fuel burning, instead of quarrelling as to their respective demerits. It is more than probable that the use of oil fuel will have a most important effect not only upon the emission of smoke, but also on the rapidity of raising dry steam. Moreover, it avoids almost entirely the troublesome question of mechanical *versus* hand stoking, and gives absolute ease of regulating the air draught. Locomotive and marine boilers have been worked to great advantage by means of oil fuel, and it is more than time that those of the large water-tube and Lancashire stationary types were also experimented with in this direction.

THE PORTSMOUTH MUNICIPAL ELECTRIC LIGHT STATION.

The following description of this station has been furnished us by Messrs. Kincaid, Waller, and Manville. We simply desire to point out that the station was duly opened on Wednesday last. A large number of guests assembled in the dynamo-room, where Alderman Ellis (the chairman of the Light Committee), Prof. Garnett, Mr. Manville, Mr. Ferranti, the Lord Mayor of Dublin, and the Mayor of Portsmouth addressed the guests, and each described some phase of the undertaking. The Lady Mayoress then turned on steam, the gigantic Ferranti armatures revolved, and the incandescent lights around the dynamo-room flashed out. All went merry as the marriage bells. As will be seen from the description, this installation differs somewhat from ordinary lines, but everyone will agree in wishing it success.

In the evening dinner was served in the Town Hall, the Mayor of Portsmouth presiding. Among the large number of guests present may be mentioned the Lord Mayor of Dublin, Mr. Alderman Ellis (the chairman of the Electric Lighting Committee), Dr. Garnett, Mr. E. Manville, Lord Crawford, Messrs. J. Kincaid, F. Ince, S. Z. de Ferranti, G. Verity, S. R. Ellis, J. G. Slatter, and many others. At the close of the proceedings, the Mayor invited the guests to go round the town and inspect the lighting, but as the time was within half an hour of midnight, very few persons made the inspection.

Historical.

The Corporation of Portsmouth applied to the Board of Trade for an electric lighting order under the Electric Lighting Acts, and statutory powers were granted by the Portsmouth Electric Lighting Order of 1890. In 1891 the Council appointed an Electric Lighting Committee to investigate the whole question of the establishment of an electricity supply station; to determine whether it was desirable that the Corporation should establish a works of their own, and if so, to lay before the Council a scheme for carrying out the powers conferred upon them by their lighting order. The members of the committee were: Alderman Emanuel, J.P., mayor; Alderman George Ellis, J.P., chairman; Alderman T. Scott Fosler, J.P., vice-chairman; Alderman Cudlipp; Councillors Beale, Ashdown, Ovens, Dean, Kimber, F. G. Foster, Croucher, Dummer, Fulljames, Dittman, Cooke, Ross, Bamber, and Merritt.

The committee carefully investigated the whole subject, and as a result they presented a report to the Council recommending that the Corporation should itself establish an electricity supply works. An engineer was retained to prepare a detailed scheme for the committee, in which a low-tension scheme was provided for, which would serve a limited area of the borough, and the permission of the Council to expend the sum provided for in this scheme was obtained. Before, however, actually proceeding with the scheme in this form, the committee investigated the working of a number of electric lighting stations in the kingdom, and came to the conclusion that a low-tension scheme would not provide adequately for the requirements of a town extending over such a large area as Portsmouth, and they therefore called in Prof. William Garnett to report to them on the relative merits of a high and low tension system. This gentleman, having thoroughly considered the subject, gave his opinion decidedly in favour of a high-tension system, and at the request of the committee furnished estimates of the capital cost of installing such a system The committee then went before the Council again to obtain its consent to this new scheme, and the Council approving of it authorised the carrying out of the works in accordance therewith, and appointed Prof. William Garnett and Messrs. Waller and Manville to act in this respect as joint engineers to the Corporation. Detail plans of the buildings and specifications of the buildings and machinery were prepared by the engineers, and a large number of tenders were received, out of which it was ultimately decided to accept the following: buildings and building work, T. W. Quick, Southsea; boilers, mechanical stokers, fuel elevator and conveyor, engines, condensers, alternators, electrical apparatus, switchboards, transformers, etc., instruments, etc., Messrs. Yates and Thom, of Blackburn, and Messrs. S. Z. de Ferranti, Limited, of London; turbo-alternator and condenser, C. A. Parsons and Co., Newcastle on-Tyne; insulated conductors, cast-iron conduits, junction-boxes, etc., the International Electric Subway Company, Limited, of London, and W. T. Glover and Co., of London and Manchester.

The Station Buildings.

The plant ultimately decided upon by the committee being in almost all respects novel and original, a detailed description of it will be of some interest. The high-tension alternating-current transformer system giving great latitude for the selection of a site, it was determined to place the generating station in proximity to the harbour, so that the economy of using condensing engines might be obtained; and a suitable position was ultimately found in proximity to the Camber and about 500 yards from the Grammar School, which forms a convenient distributing point from whence the supply mains radiate to Southsea, Portsea, and Landport. The proximity of the site to the Camber further enables coal to be delivered by water practically at the door of the generating station, further securing an important economy. Upon a portion of the site extensive buildings have been erected, in the design of which great care has been exercised so as to provide for a most efficient arrangement of the plant and apparatus in connection therewith, and to allow of future extensions being economically and efficiently carried out. The buildings consist of a boiler, economiser, and engine-house, with a coal store convenient to the boilers, and ample set of offices over the coal-store, and stores, test-rooms, etc., adjoining the engine-house. The ground not yet occupied will ultimately provide a second boiler-house on the other side of the coal-store, which will then be central to the two ranges of boilers; and it is anticipated that the engine-house will be large enough to contain the total plant required to completely utilise the steam produced by the two ranges of boilers. The engine-house is 102ft. 6in. long by 66ft. wide, and 32ft. high to the centre of the roof, and is spanned by a travelling crane which travels the whole engine-house from end to end, and is capable of lifting a weight of at least 10 tons.

Immediately outside the coal-store a chimney shaft has been erected, 120ft. high and 6ft. square inside at the base. The foundations of this chimney are of somewhat original design. It being found that within a few feet of the surface was a bed of shingle, upwards of 22ft. in depth, permeated with water, ordinary foundation, involving close cofferdams and pumping, was considered too expensive an operation, and it was decided to build the chimney upon a concrete "raft." A bed of concrete 20ft. square, and about 6ft. in thickness, bound together in both directions by steel joists, forms this "raft," and distributes the weight of the chimney, so that a pressure of not more than a ton to the square foot is transmitted to the bed of shingle. An important feature in the design of the buildings is the position of the engineer's office. This forms the roof of the economiser-house, and is built in between the walls of the engine-house and boiler-house, and has a cast-iron balcony projecting into each of these houses. The engineer in charge can thus watch the working of the machinery both in the engine-house and boiler-house without the necessity of leaving this room, whilst a staircase from the balconies enables him to get direct into either building. The rooms off the engine-house consist of a large store, the recorder-room, the motor commutator-room, the test-room, and—a not unimportant feature in a building of this kind—a mess-room for the workmen, and a properly fitted lavatory.

Digitized by Google

The Boiler-house.

The boiler-house contains a range of five Lancashire boilers fitted with all the most modern appliances for labour saving. The relative merits of the various types of boilers were carefully considered by the engineers, and in the end it was considered that either tubulous boilers of the Babcock and Wilcox type or Lancashire boilers would be the most suitable. Seeing that "Sunny Southsea" and Portsmouth are never visited by fogs, and that, therefore, the demand for steam upon the boilers could be accurately ascertained from hour to hour at any season of the year, it was decided to instal Lancashire boilers, having due regard to their simplicity, excellent evaporative qualities, and small cost of maintenance. The first range of boilers, five in number, are each 7ft. 6in. in internal diameter, and 30ft. in length. They are constructed to withstand a daily working pressure of 160lb. to the square inch, although it is not intended to work them at a pressure exceeding 140lb. to the square inch, the balance between that and the working pressure for which they have been designed being allowed for the drop in pressure that will be required from time to time by the insurance companies as the boilers wear, and which will thus provide for the lapse of a number of years before getting below the economical working pressure for the engines. The boilers are fitted with Vicars mechanical stokers and furnaces, and coal is conveyed to the hoppers of these stokers by a conveyor running across the boiler-house directly over the hoppers. An elevator in the coal-store outside the boiler-house wall raises the coal and delivers it to the conveyor, and the elevator is of sufficient size to deliver coal also to a second conveyor, which will ultimately be installed to serve the second range of five boilers when these are erected. Two small vertical high-pressure engines are provided under the elevator to drive the elevator, conveyor, and mechanical stokers, these engines being in duplicate, so that a breakdown of one may not interfere with the proper working of this gear.

A large damper in the main flue between the economiser and the chimney shaft is connected to a hand-wheel in front of the boilers, so that the draught may be regulated from that end without the stoker leaving his place, and it is hoped that by this complete arrangement for the stoking and regulation of the boilers the minimum of hand-labour may be required for the raising of the steam, and that coal of a cheap quality may be economically and unobjectionably used. The flues behind the boilers are in duplicate, and in one of them the three sections of the economiser is placed, numbering in all 288 heating pipes. The flues are so arranged with dampers that the products of combustion can be either passed through the economiser or through the second flue when the economiser requires cleaning out or repairs, and these two flues are so arranged that they can ultimately be extended to a second chimney shaft that will be erected next the second range of boilers, so that either or both chimneys will serve either or both ranges of boilers. The scrapers on the economiser, and likewise the stirrer in the water-purifier, are driven by Brown alternating-current motors in place of steam-engines. In a small room adjoining the boiler-house are placed the feed pumps. These are not of the ordinary direct-acting type, but consist of vertical simple engines driving three-throw pumps through helical gearing, this arrangement of pumps having the advantage that the engine driving them has a proper cut-off and allows for the economical use of the steam required to drive them, whilst the ability to put out of action any one of the pumps and to alter the speed of the engine gives almost equal range of feed with that obtained with direct-acting pumps. The pumps derive their water supply either direct from the town mains or from a water-storage tank, capable of containing 20,000 gallons of water, erected on the roof of the men's mess-room. The suction pipes are in duplicate, and the feed pipes from the boilers are also completely in duplicate, each boiler being connected to both ranges through separate feed back-pressure valves, and each range is connected to the economiser, so that the water pumped through it can be sent either through the economiser tubes to the boilers, or direct to the boilers. The town water supply in Portsmouth being of exceptional hardness, a water-purifying apparatus has been provided next the storage tank referred to. This has been provided by the Stanhope Water Engineering Company, and is of sufficient size to purify 2,000 gallons of water per hour.

The Steam-pipes.

The engineers have bestowed special care in the arrangement and construction of the steam-pipe connections between the boilers and the engines, considering that immunity from breakdowns is to a large extent dependent thereon, and in place of arranging the steam-pipes in a ring main, two entirely separate ranges of main and branch steam-pipes have been provided, so that each engine has two separate connections to the boilers. Each boiler is provided with two stand-pipes terminating in stop-valves, each of these stop-valves being connected through 6ft. spring lengths with each of the separate ranges running across the boilers. These main ranges, which are 10in. in internal diameter, are provided each one with a through valve immediately where the ranges pass away from the boilers. The steam-pipes are carried across the economiser flue to a common point within the engine-room, and are then continued one range over the other down the centre of the engine-room. Branch pipes, 5in. in internal diameter, connect each range separately to each engine, and a stop-valve is provided at the root of each branch pipe where it joins the main, in addition to the two stop-valves on each engine. This double system of steam connection has been carried out even to the smallest engines employed, so that no portion of the plant is likely to fall short of a supply of steam through accident. A water-separator is inserted in the run of each steam-pipe just before it reaches the engine-room wall, to ensure the steam being freed from water before reaching the engines, and at the extreme end of the steam-pipes water-catchers are provided to receive the condensed water therefrom, and both the water-catchers and the water-separators are connected with the drains through suitable steam-traps. The greatest care has been exercised in the construction of all the steam-pipes. Both the mains and branches, with the exception of the branches to the pumps and conveyor engines, are made of mild steel plates manufactured by the Steel Company of Scotland. The requisite allowance for expansion and contraction has been provided for without the provision of any expansion joint, the steam-pipes being so arranged that long legs are formed at right angles to the main run of the pipes, these legs having sufficient elasticity in themselves to allow for the elongation of the main pipes.

The Engines and Alternators.

The slow-speed engines and alternators are perhaps the most interesting feature in the installation. In the preliminary stages, when the type of plant to be provided for was being considered by the committee and their engineers, it was wished that slow-speed compound engines, coupled direct to alternators and running at the same speed, might be used, but the estimated cost of such a plant, owing to the very low speed of the alternators, appeared prohibitive. In the specification issued, therefore, coupled compound engines, driving alternators by ropes, were provided for. Messrs. Ferranti, and Yates and Thom, however, in addition to tendering for engines and alternators geared together by ropes, tendered alternatively for the combination of the two at a price which was below the lowest tender received for the machines separately, and the committee recommended the Council to accept this very favourable offer. These machines may perhaps be properly described as engine-alternators, since the alternators are not coupled to the engines, but form an integral portion of them. The engines are of the usual coupled compound type—*i.e.*, the high and low pressure cylinders arranged one at each end of the crankshaft, the fly-wheel being in the centre, and having upon its periphery the field magnets, which revolve inside the stationary armature. Two sets of these engine alternators have been provided in the first instance. The high-pressure cylinder of each engine is 15in. in diameter and the low-pressure 28in. in diameter, the stroke being 36in. These cylinder dimensions were arrived at after mature consideration of the most desirable point in the load of the engine at which to obtain the maximum economy, and seeing that the time during which the engines will ever be working at their full load is but a very small proportion of the time in which a heavy load is on the station, and a still much smaller proportion of the whole 24 hours' running, the engineers thought it desirable to obtain the greatest economy in steam consumption when the engines were running at three-quarters of their normal maximum load. Of course, the engines are of ample size to develop the full output of the alternators, although the work obtained between three-quarters and full load will not be so economical as that obtained at three-quarters load. The valve motions of both high and low pressure cylinders are Messrs. Yates and Thom's improved form of Corliss gear, and the Corliss gear on both cylinders is controlled by a very sensitive form of governor. The governor itself is further provided with a compensator, which delicately readjusts the speed of the engine so as to maintain a practically constant speed under all loads. All the mechanical proportions of the engine are of ample strength for the work required of them, the crankshafts being of a particularly large section—viz., 9in. diameter by 18in. long in the bearings, swelled to 12in. in diameter at the flywheel. The flywheels are 14ft. in diameter, made in halves, and are turned up flat on the periphery and bored in 64 places, arranged equidistant to receive the field magnet cores and pole-pieces. The weight of each fly-wheel is 12 tons, of which the rim alone weighs seven. This weight is exclusive of the weight of the magnets.

Each engine is provided with a separate jet condenser. The air-pumps lie in chambers between the cylinders of the engines, and are worked by rocking beams off the cross-heads of the cylinders. The cylinders are steam-jacketed, and provision has been made for admitting high-pressure steam to the low-pressure cylinder to facilitate starting. The condensers are connected up to an intake pipe 14in. in diameter, which lies in the trench behind the cylinders, and is carried 250 yards to a point in the Camber where tolerably clean sea-water is obtainable. The discharge of the condenser is connected to a discharge pipe 16in. in diameter, also contained in the trench behind the cylinders, which discharges its water into the Camber. In this trench is likewise contained an auxiliary exhaust-pipe, for use when the condensers of any engine may be temporarily out of order, and the engines are so connected to the condensers and to the auxiliary exhaust-pipe that either may be used for receiving the exhaust steam at will. The engines are completely equipped with indicating gear, lubricators on the most modern principle are provided, and the working parts are railed in.

There are many points of novelty in connection with the design and construction of the alternators. As before mentioned, the flywheels of the engines contain upon them the field magnets with their coils. The magnets are 64 in number, and consist of a wrought-iron core, 9½in. long by 5in. in dinmeter, with pole-pieces formed at their outer ends the full width of the armatures. The cores are bolted through the periphery of the flywheel, and are securely fastened on the inner side. Each magnet core is wound with flat copper strip 1⅛in. wide by ¼in. thick, wound in one length into a spiral in a special machine, one side of the strip being covered with shellaced paper. The spiral is compressed

Digitized by Google

over a vulcanised fibre, and finished off with vulcanised fibre, cheeks top and bottom, each bobbin so formed being slipped over the magnet core and securely fastened thereto before the core is placed in position on the flywheel. The insulation on the winding of copper strip being out of sight, the magnet windings present to view only bare copper. The section of the copper strip in the winding is such that the difference of potential used to excite the magnets when coupled up never exceeds 46 volts. It will therefore be seen that the flywheel might be washed down from a hose whilst excited without interfering with its insulation to such an extent as to appreciably affect the excitation of the field magnets. Round the flywheel stands the frame which contains the armature sections. The frame is 16ft. 8in. external diameter, and 17in. wide, of cast iron, and made in four pieces bolted together by internal flanges, and having projecting feet which rest on two base-plates for supporting the armature frame in position. The frame is a moulded U section turned on its inside faces, and into the annular recess so formed are fitted segmental blocks made up of wrought-iron stampings, thus forming a continuous wrought-iron armature core round the field magnets. Each wrought-iron laminated block is pierced with seven slot holes from side to side, and is fitted at each side with a gunmetal box having corresponding holes and provided with lids. These boxes and segments are bolted up together in one solid block by means of manganese bronze bolts passing through two of the above-mentioned slot holes, which also keys the whole firmly together. The four holes furthest from the centres of the segmental blocks are fitted with mica tubes, and through these the armature wire is wound, the ends of the coils resting entirely within the bronze boxes. These boxes are run in solid with insulating composition, and then have the lids screwed on. Every part of the armature is, therefore, encased in and protected by metal, no insulation even being visible. Probably no more substantial and endurable alternator than those above described has yet been built. The impossibility of affecting the field magnet windings by water or in any way breaking down their insulation, the complete encasing of the armature windings so that these are not exposed to any external injury or to the influence of damp or dirt, the great ease with which an armature section can be rewound in position should its insulation fail, and the corresponding ease with which a complete armature section with its winding can be removed from the frame and replaced with a complete spare section, are points which the designers hope will commend themselves to every engineer.

There being no losses due to mechanical friction, the electrical efficiency of the alternator is the commercial efficiency of the whole machine. The maximum current required for exciting the fields is under 2½ per cent., the losses due to resistance in the armature coils is 1 per cent., and the losses due to hysteresis 1¾ per cent. It was at first contemplated mounting the exciter on the crankshaft of the engine in the same way as the alternator fields, but the difficulty of effecting repairs to the armature of the exciter induced the engineers to arrange for separate exciters to be provided, which stand at the outside edge of the alternator armature frame, and are driven by ropes off a pulley on the engine crankshaft. These engine alternators have, it is claimed, even greater advantages, from an efficiency point of view than dynamos coupled direct to either low or high speed engines, since the only bearings are the two main bearings peculiar to engines of this type, and there are no extra bearings in which further frictional losses may be sustained. It will therefore, for the first time in this country, be possible to compare the total efficiency of an engine dynamo of this class with direct-coupled plant of the other types that have been for so long in use here. Two of these engine alternators are at present at work at the central station, placed back-to-back across the width of the engine-room, as will be seen from the plan and section, and the station is capable of containing some 10 such sets banked in the same manner. The output of each of these engine alternators, according to the contract, is 212 kilowatts, but it is anticipated that an output of 300 kilowatts can be obtained from them with safety.

The committee determined that they would try with these, the slowest-speed direct-coupled alternators in the country, a type of alternator of exactly the opposite description—viz., Mr. Parsons's turbo-alternator, and side by side with these large slow-speed machines has been erected one of these turbo-alternators. In general construction it is of the same description as those that have been provided for the Scarborough and Cambridge electric supply stations. Its chief point of difference is the comparatively slow speed at which it runs. It is constructed to give a full output of 150 kilowatts at 3,000 revolutions per minute, and, of course, as in the case of the larger machines, its periodicity is 50 complete phases per second. An independent condenser is provided for it, the air-pump being of the tandem compound type and is driven by a vertical tandem compound engine mounted directly over the pump. Both the turbo-alternator and the condenser engine are connected, in the same way as the larger engines, with the two independent main ranges of steam-pipes.

The Main Switchboard.

In the centre of the engine-house, directly under the balcony outside the engineer's office, is erected the switch platform with the main switchboard. This main switchboard has been designed to be of as simple a form as possible, and is very similar to the distributing switchboard used at the sub-stations of the London Electric Supply Corporation and in the generating station at Havre. The framework is of slate construction, and is arranged with horizontal and vertical slabs, so that each switch and each cut-out is contained within a separate compartment. All the current-carrying parts are mounted upon sulphur insulators. The current from the armatures of the alternators is brought on both sides to circular omnibus bars, these omnibus bars being cut into sections, which can be joined up continuously by removable switches on the insulated side and by links on the "earth" side. The current is fed into the omnibus bar on the insulated side through single-pole switches of very strong construction. The synchronising, as well as the joining into circuit of each alternator, is performed by the same switch, a subsidiary contact-piece being provided in the path of the switch before it reaches its main contact, this subsidiary contact being in connection with the synchronising transformers and their indicating voltmeter. The switchboard attendant, therefore, in placing a new alternator into circuit first of all puts his switch half on, until the new machine synchronises with those already running, and when this happens put it over into its main contact. Fusible cut-outs of Ferranti's "dipping" pattern are provided immediately where each dynamo connection reaches the switchboard and immediately where each circuit leaves the main switchboard. These cut-outs consist of an earthenware pot divided into two long compartments by an earthenware partition in the centre. These compartments are filled with oil, and the current passes between two brass springs, one in each compartment, through a thin copper wire fastened over the central partition. The springs are prevented from dipping themselves beneath the oil by the copper wire resting on the partition, but when this wire is fused through excess of current these springs immediately dip themselves beneath the oil, thus effectually extinguishing the arc. An ammeter is provided on each dynamo circuit and on each main circuit, and two voltmeters with large dials and transformers are placed over the switchboard to indicate the E.M F. of the circuits. The circular divided omnibus bar enables all the dynamos to be run in parallel on all the circuits, or any single dynamo to be run on any circuit. Six dynamo switches are provided and six circuit switches. The regulating switches for controlling the E.M.F. at the terminals of the generators stand on the platform in front of the main switchboard. They consist of resistance coils placed as a shunt to the fields of each exciter, the E.M.F. of the exciting current being thus reduced or increased according to the extent to which the field is shunted. One of these switches is provided in connection with each exciter, and the resistance and switch, being arranged in the shape of a standard on the switch platform with a hand-wheel at the top, forms a neat and effective arrangement.

The engineers considering it important that a record should be kept, not only of the current output of the station on private lighting circuits, but of the pressure from moment to moment at which that current output is being provided, an elaborate recorder has been constructed for the purpose by Messrs. Nalder Brothers. It is provided for six circuits, and registers both the E.M.F. and intensity of the current passing to each circuit. A clock of good construction drives a line of shafting, over which the recording papers pass and are propelled. The papers move at the rate of one eighth of an inch per minute, and therefore show easily even momentary fluctuations in E.M F. The recorder is mounted upon the "earth" side of the system just before the circuits are connected with "earth," and is therefore perfectly safe for handling by the attendants in the station.

Public Lighting.

All the principal streets are lighted by electricity, and the arrangements, both in producing the current for the public lighting, and in utilising it, are novel. It has heretofore been the practice to run arc lamps used for public lighting in towns during all the hours of darkness. Obviously, there is no need for this, a good light only being required till midnight, and a much smaller light being sufficient from that time until dawn. The engineers, therefore, recommended the Corporation to have their arc lamp-posts fitted with two 32-c.p. incandescent lamps in addition to the arc lamp. The incandescent lamps are run in parallel off the low-tension distribution mains referred to hereafter, whilst the arc lamps are run in long series off the arc lighting mains, also described hereafter. The connections to the incandescent lamps are made through fusible cut-outs and properly designed switches contained in the base of the lamp-posts. The switches are arranged so that they can be turned from the outside of the lamp-post without opening any door. For the present the incandescent lamps will be switched on at 12 o'clock midnight by hand and extinguished at dawn by the same means, but it is hoped shortly to introduce a clock switch in each lamp-post, which will always close the incandescent circuit at midnight, and will open the circuit again at varying times, according to the season of the year, in the same manner as an alarum clock is set.

The arc lamps are all of the Brockie-Pell double-carbon type arranged to burn upwards of 30 hours without retrimming, and the total number in use at present is 102. In the base of each lamp, in addition to the incandescent lamp switch and cut-out, is an arc light switch, arranged to completely cut the arc lamp out of circuit, and at the same time to connect across the arc lighting mains when this is effected, thus placing a lamp-trimmer out of any possible danger when attending to the lamp whilst the current is on the circuit. A very interesting point in connection with the arc lighting is the method of producing the current. Heretofore it has been the usual practice, in the case where the public lighting is provided in addition to the private lighting, that an entirely separate plant adapted for running the arc lamps in series is used for the production of the current, the plant generally consisting of three or four sets of engines of comparatively small power, say 60 h.p. to 70 h.p., running high-

Digitized by Google

tension continuous-current machines—the disadvantages of this arrangement being that the engines, owing to their small size, are not efficient, and that during the greater number of the hours of darkness the private lighting plant is running with practically no load upon it, and, therefore, at a greater disadvantage than would be the case if the public lighting were effected from the same source. Mr. Ferranti being able, at the time this contract was settled, to satisfy the engineers that he had produced a practical motor commutator commutating alternating currents into direct ones, it was settled by the committee to adopt this method of supplying current to the arc lamps, and to thus keep a load on the private lighting system all night long. The motor commutator consists essentially of a synchronous self-starting motor, the fields of which are excited by its own commutated current. This motor carries at each end of its spindle a commutator, the alternate sections of which are joined together in parallel, and each of the two groups of sections so formed are joined in series to the two groups of sections of the commutator at the other end of the spindle, this arrangement enabling a double break to be provided at the moment of commutation. The sections of the commutator are separated from each other on the periphery by air breaks, and the body of the commutator, which is hollow, is ingeniously arranged so that a current of air is fanned outwards, between the sections of the commutator as it revolves, the result being that the sparking at the commutator when in action is no greater and of no more destructive effect than that seen at the commutator of the well-known types of arc lighting dynamos.

The equipment of the generating station is completed by the addition of a very complete test-room, in which is placed all the standard instruments from which the various instruments on the switchboards are from time to time calibrated, and also the apparatus requisite for ascertaining with great accuracy the insulation condition of the mains from time to time. Most of these have been manufactured by Messrs. Nalder Bros. and Co. A special piece of apparatus has been provided in this room for the calibration of the meters. It consists of a transformer, the primary of which is fed at 100 volts from the local lighting circuit in the station, and the secondary of which is arranged on several sets of terminals, to give a difference of potential from ten to two volts, and further adjustment of this difference of potential is obtained by the adjustment of the core within the transformer. This transformer is connected up to a divided circular omnibus bar connected across by links, and each section of the bar is provided with plug holes, by means of which a meter may be inserted in series with the remainder of the bar, the link being withdrawn after the meter is inserted. Thus a number of meters can be placed in series with each other, and the current through all of them adjusted with the greatest of ease by shifting the connections of the omnibus bar to the various terminals on the transformer, and finally adjusting by moving the core.

The Method of Distribution.

In designing the system of distribution, the engineers gave all consideration to overcoming, as far as possible, the losses inherent in alternating-current transformer systems. The placing of a separate transformer in each building to be lighted was discarded by them owing to its great inefficiency, and they ultimately had to decide between the grouping of transformers in banks in distributing-chambers, at some distance from each other, and the use of a three-wire system for conveying a low-tension current to the consumers' premises, or the placing of separate transformers in boxes beneath the street surface at frequent intervals, feeding into a low-tension two-wire system. Due consideration was given to both these systems, and the greater flexibility of the latter finally decided them to adopt it. The sizes of the low-tension distribution mains have been so arranged that when fully loaded the transformer-boxes shall not be nearer to each other than 300 yard centres; and to further ensure a good efficiency from the transformers the majority of them have been fitted with hand switches, operated through a hole in the street cover, and so arranged that the connections of the transformers can be altered at different seasons of the year, and even daily if found desirable, so that they may either give their maximum efficiency at full load or at third load; and the section of conductor on the transformer is so ample that even if by accident a transformer be switched down to a full efficiency at third load, and left so when full load is on the transformer, no danger of overheating is incurred by the transformer, the only effect produced being an unreasonable drop in volts on the main supplying the consumers nearest that particular transformer. The boxes containing the transformers are of cast iron, and are placed in brick chambers constructed beneath the pavement-level. The space occupied by the transformer proper is entirely filled in with oil, and an upper compartment contains the high-tension fusible cut-out, the switch before referred to, and the Cardew earthing device. The box is then covered in with an airtight cover, and the conductors are led into the box through air and water tight glands, and a second cover is provided to the brick chamber on the street-level covering in the whole of the gear.

Three separate sets of conductors have had to be provided: (1) high-tension feeders to supply the primary windings of the various transformers, (2) low-tension distribution wires receiving the low-tension current from the transformers and distributing it to the premises of the consumers, and (3) high-tension arc lighting mains connecting the arc lamps in series of about 40 each. The high-tension feeders and the arc lighting mains proceed straight from the generating station, but the low-tension distribution wires are entirely disconnected from the generating station, and are only connected with the transformers which feed into them. Alternative tenders were obtained by the engineers for the committee for the use of either armoured cables laid direct in the earth or unarmoured cables drawn into metallic conduits; and, finally, the joint tender of the International Electric Subway Company, of London, and Messrs. W. T. Glover and Co., of Salford, was accepted for this work, the former supplying the conduit and the latter both high and low tension conductors. The Board of Trade requiring that high and low tension conductors shall be well separated from each other by metallic partitions, the Johnson conduit lends itself admirably to this purpose. Two types of this conduit have been used—one having three ducts, each 2½in. square, side by side; the other having two ducts of the same size side by side. The three-way conduit is principally used wherever there are low-tension distribution wires, whilst the two-way duct is used in streets in which there is no likelihood of a demand for private lighting, but through which the high-tension feeders and arc light conductors have to pass.

The conduit is a cast-iron structure composed of two troughs, one placed upon the other, a groove being cast on the edge of the lower and a tongue on the edge of the upper one, so that when put together they exactly fit. The whole of the cast-iron work is coated with Dr. Angus Smith's preservative solution, which renders it very durable. The conduit is divided into two or three ducts, or compartments, as is desired, by means of iron partitions cast on the bottom trough. The rapidity with which the system can be laid is a most favourable feature. The great advantage offered by this form of conduit is the facility with which any of the conductors can be reached along the length of the conduit. The method of drawing in the cables into the ducts is the same as if these latter were separate cast-iron pipes. At suitable intervals a brick drawing-in box has been constructed, fitted with a road-box cover, and the ends of the conduits protrude through the sides of these chambers. The adoption of this conduit system for the first time on a large scale in England will doubtless prove of considerable interest to engineers who may have to consider the provisions of a group of ducts.

The conductors referred to above are of two types—those for the high-tension feeders and for the arc light cables being concentric, and with indiarubber insulation of the highest quality, tested to 5,000 megohms per mile between the inner and outer conductor; those for the low-tension distribution wires being separate cables instead of concentric, and of a lower insulation resistance. The high-tension feeders run continuously through all the streets at present to be served. A distribution-chamber has been constructed opposite the Grammar School, which forms a central point at which three out of the four high-tension feeder circuits converge, and from this distribution-chamber to the generating station two heavy feeders are laid, to one of which the two lighter of the branch feeders are joined, to the other of which the heavier of the branch feeders is joined. Ultimately, a third feeder will be laid from the generating station to separate the two feeders at present joined to the one heavy feeder, when the density of the lighting justifies this being carried out. Of these three-branch high-tension feeders one is carried nearly the whole distance of the Commercial-road, as far as All Saints' Church, and feeds the Landport district; a second one proceeds along King's-road and Elm-grove, supplying a portion of Southsea; and the third along the Terraces and Palmerston-road and High-street, supplying the remainder of Southsea. The fourth high-tension feeder—*i.e*, that supplying The Hard and Queen-street, serving the district of Portsea, which proceeds in an entirely different direction, is taken direct from the generating station without being carried through the distribution-chamber. The arc light circuits in the same way are carried through the distribution-chamber to the generating station, with the exception of that supplying The Hard and Queen-street, which, as in the case of the high-tension feeder, also proceeds direct from the station. The high-tension feeder being concentric, it was considered inadvisable by the engineers to make any T-joints on to it wherewith to feed into the transformers, and in each case where the high-tension feeder passes a transformer it is cut in two, and the ends led out from the conduit into a high-tension junction-box, and again from the other side of the junction-box into the conduit. Within the junction-box the ends of the two conductors of the concentric cable are made continuous through concentric rings connecting together the respective conductors. These concentric rings are made in sections clamped together, and so arranged that from the two sides of the junction-box unoccupied by the main feeder, branch connections can be taken either to the transformer-box or to a sub-branch feeder proceeding down side streets off the main streets, and any of these branch circuits can be readily disconnected from the high-tension feeder when required, and, as will be seen, the high-tension feeder itself can be broken up into comparatively short lengths for isolating faults and for executing repairs on faulty sections; and to provide against a discontinuance of the supply of electrical energy on any section, excepting the one under repair, the high-tension feeders, as they are extended, in course of time will be carried round to form ring circuits. The conductors enter the high-tension junction-box through double glands in the sides of the box, each gland consisting of a number of rubber rings, not less than four in number, compressed around the conductor inside a substantial stuffing-box. Two covers are provided for the junction-box, the inner one having a watertight joint made through a rubber ring, the outer one being an ordinary street-box cover. The air contained in the junction-box when the joints are made is freed from moisture by a plate of chloride of calcium placed on the bottom of the box. Both the high-tension feeders and junction-boxes have been tested under current with 4,000 volts difference of potential, and have proved entirely satisfactory.

The engineers decided that in place of using a heavy con-

Digitized by Google

ductor for the low-tension distribution wires they would use one section of conductor, and lay one, two, or three pairs of mains, according to the demand in the respective sections of each street, and the area of this low-tension conductor is ·0349 square inch section. As there are in those portions of the streets in which a considerable demand is experienced three pairs of these conductors, it became necessary, to distinguish each conductor along its whole run, to facilitate the joining up of the buildings on to the proper pair of conductors; and to ensure the recognition of each conductor, the coverings of the conductors are coloured—three red and three black, the black wires being in all cases positive, the red wires negative. Each of the three conductors, whether they be black or red, are further distinguished from each other by employing three different types of braiding, each of which has the advantage of not only appealing to the sight but also to the touch, and even in the dark a jointer can recognise any pair of cables he wishes. As in the case of the high-tension feeders these low-tension distribution wires are not carried directly into the transformer secondary terminals, but are carried into low-tension junction-boxes, which boxes are connected with the low-tension side of the transformer, and the design of these differs materially from that of the high-tension junction-boxes. Three sides of the low-tension junction-box are fitted each side with three pairs of glands, the fourth side being fitted with one pair of large glands. The heavy conductor from the transformer-chamber, usually 37/12 S.W.G., is carried through the pair of large glands to terminals within the junction-box. These terminals are connected to the distribution blocks through fusible cut-outs consisting of copper wires, contained in glass tubes to prevent injury to the fittings on the melting, and consequent arcing, of the fuse. All the low-tension distribution wires are sweated into sockets, which are secured by studs and nuts to the distribution blocks, of which there are three pairs facing the three sets of glands. The three distribution blocks are connected together with brass links, so that any one can be disconnected from the low-tension side of the transformer, and any pair of low-tension wires can be disconnected from the distribution blocks, isolating that particular pair only whilst a joint is being made, or for testing purposes.

The great flexibility aimed at in the design of these low-tension junction-boxes will be readily seen. It enables the low-tension wires throughout the whole system to be connected in the simplest manner possible in one continuous length, fed into at intervals by the transformers; or it enables each 300 yards of low-tension wire to be fed into by a single transformer, entirely disconnected on its secondary side from everything else but this particular section; or it enables several transformers with their respective sections to work in parallel, but entirely disconnected from the remainder of the low-tension system—in addition to the facilities for testing and joining up consumers' houses mentioned above. Again, the interposition of fusible cut-outs, not along the run of the low-tension mains, but between the low-tension main and each transformer, provides, with almost certainty, in case of accident to a transformer, for the fusing of its connection by the sum of the current sent through the low-tension mains from the transformers on each side of the faulty one, without the fuse of these latter transformers being melted, and the only inconvenience suffered by customers in the vicinity of this particular transformer would then be a drop in potential due to the greater length through which current would have to be conducted to their premises by the transformers on each side of the faulty one.

The transformers used are of three sizes—15, 25, and 30 kilowatts each. It will be noticed that where 30-kilowatt transformers are used the three pairs of conductors, each of ·0349 square inch section, have insufficient current-carrying capacity to distribute the output of a transformer of this size, and in all cases where this size transformer is used, the transformer and junction boxes are placed directly opposite the premises of a large consumer, who obtains the supply direct from the junction-box, without utilising the carrying capacity of the three pairs of low-tension conductors, which then only carry the balance of the output of the transformer to the smaller premises on each side. In joining the arc lamps in series to their conductors no special form of junction-box has been used. Care has been taken in arranging the position of the drawing-in boxes that one of these is placed opposite each arc lamp-post, and the arc light concentric conductor is divided in its outer conductor, and the two ends of the outer conductor joined to two separate 7/16 conductors, which are carried through a 2in. coated steam-barrel direct to the base of the lamp-post. The low-tension distribution wires are also tapped in this drawing-in box to supply current to the two 32-c.p. lamps contained on each lamp-post in addition to the arc lamp. This branch wire is a twin 3/20 S.W.G. wire, sheathed in lead to protect it from contact with the high-tension arc lighting wires, and carried to the base of the lamp-post through the same 2in. pipe as the former conductors. Several modifications of the ordinary methods of drawing-in and jointing the cables have been adopted by Messrs. Glover and Co. in carrying out this contract. The usual method of stripping the cable, turning back the conductor, and tying on a rope to haul it through the duct, is deleterious to the conductor, especially if any hard pull has to be used, and tends to mechanically weaken the insulation. In the drawing of these cables, however, the Voisey grip was used. This apparatus grips the conductor most effectively, and is easily attached to it. All joints on the conductors, some of which are of considerable size, have been well vulcanised, and the vulcanising of these joints has been carried out *in situ* by means of the portable vulcaniser made by Messrs. Glover and Co.

It will be appreciated by engineers that the extreme novelty of most of the plant used in this station might have been anticipated to have led to difficulties in the putting to work of the station, and credit is due to the contractors that the whole of the machinery has worked from the start with as great reliability as if it had been plant of less novel construction.

THE PACIFIC CABLE QUESTION.

Sir J. Pender has addressed the following further letter to Sir Charles Tupper in reply to the communication from the latter which was printed in our issue of 25th ult.:

Winchester House, Old Broad-street, E.C., May 30.

Dear Sir Charles Tupper,—Absence from home has alone prevented me from replying to your letter of the 17th instant earlier.

First.—Permit me to point out that although it be true that certain of the Australasian Governments have from time to time granted subsidies and guarantees to the Eastern Extension Telegraph Company, my statement that telegraphic communication with Australia was established solely by private enterprise is quite accurate, the subsidies and guarantees having been given for specific purposes other than the establishment of the communication. For instance, the subsidies were granted to enable the company to duplicate the Australian section of the line, not because it was unequal to the traffic requirements, but because the Governments and telegraphing public had found to their cost that no confidence could be placed in a single line; and as my experience fully bears out this view, I contend that if a Pacific cable is to afford the same measure of security as the existing system it must be duplicated. The guarantees were granted, as you are aware, to obtain the substantial reduction of tariff from 9s. 4d. to 4s. per word.

Secondly.—Your reference to the Berne list as your authority for stating that the Eastern Extension Company's original cables, although more than 20 years old, were still in working order, explains how you have been misled in the matter, the list only giving the dates when the early cables were first laid with their respective lengths, without showing the extensive cable renewals which have since been found necessary.

Thirdly.—As to the question of monopoly, I find on looking through the official report of the Colonial Conference (1887) that the remarks attributed to the late Mr. Raikes really referred to the following paragraph of a paper which Mr. Sandford Fleming read to the conference immediately before Mr. Raikes addressed the delegates—namely:

"Mr. Pender submits that the existing company (Eastern Extension Company) as the pioneer of telegraphic communication with Australia, is entitled to a large share of consideration at the hands of the colonies."

Consequently to represent this perfectly reasonable contention as a claim to a monopoly is simply absurd.

But none of these points have any important bearing on the real question at issue—namely, is the proposed Pacific cable an undertaking which can be recommended to the investing public?

The Pacific cable project, as I understand it, is as follows:

It is proposed to lay a single line of cable connecting Canada with Australia at a cost of £1.800,000, and in order to raise this sum guarantees for 14 years from the several Governments supposed to be interested to the amount of £72,000 per annum are to be obtained.

Now let us examine this proposal from the point of view of an intending investor:

Capital.			£1,800,000
Working expenses	£25,000		
Maintenance	35,000		
		£60,000*	
(*Note.—This is Mr. Sandford Fleming's own calculation.)			
Amortisation to replace capital at end of 14 years' guarantee	105,000		
			£165,000
Less earnings estimated on basis of one-half of the Eastern Extension Company's receipts from the Australasian traffic	45,000		
Four per cent. guarantee	72,000		
			£117,000
Leaving an actual loss to investors of (per annum) ..			£48,000

Suppose, for the sake of argument, we assume that the Pacific cable might one way or another obtain as much as the whole of the Eastern Extension Company's present Australasian receipts, even then there would be absolutely no return on the capital invested, and if the Pacific cable were duplicated the loss would probably amount to £120,000 per annum.

The above figures will, I am sure, be regarded by all conversant with the expenses attending the working and maintenance of cables laid in deep seas as not only moderate, but rather under the mark; for it must not be overlooked that no allowance is made for a prolonged interruption, a contingency which is very probable to a single cable laid in such extreme depths as have been proved to exist in the Pacific, and during which interruption the guarantees would, of course, cease to be paid.

I observe with some surprise that you quote with approval an-

Digitized by Google

article which appeared in the *Globe*. It is evident that the writer knows very little of the subject, for he says in case of the cables between Aden and England being injured, all communication with India would be interrupted. As a matter of fact, no fewer than three other routes practically under the control of the existing system would still be open for traffic.

Again, I fail to understand on what grounds the writer holds that a single line of cable nearly 9,000 nautical miles in length laid in the Pacific should stand less chance of interruption than the existing cables.

With such figures as I have above placed before you, and which as a director of a submarine cable company you can fully appreciate, I would ask whether you would consider yourself justified in putting your name to a prospectus inviting subscriptions from the public for a scheme showing such disastrous financial results, even with the aid of the suggested Government guarantees.

I remain yours faithfully,

JOHN PENDER.

P.S.—I am sending a copy of this letter to the *Times*.

COUNTRY HOUSE ELECTRIC LIGHTING.*

BY SIDNEY A. COURT.

Large country houses, when in an isolated position, and out of reach of a gas company's supply main, are now usually lighted by means of electricity. By a country house the author means any large private house containing some 30 or more rooms, and requiring 100 or more points of light. Of such houses there are a great number in the United Kingdom, chiefly owned by comparatively well-off persons, who can afford to pay much more for the burning of a cleanly and steady source of light than they would for lighting by means of oil lamps. The lighting of small country houses is at present chiefly carried out by means of paraffin oil lamps, which necessitate a lamp-room, and the cleaning, filling, and trimming of the lamps regularly every day, and this is at once the cheapest and most convenient method of lighting where the total number of points required is below 100, but when above this number the work of cleaning and attending to the lamps becomes heavy, and in establishments where water has to be pumped for domestic use, or where the proximity of the "home farm" will conveniently allow it, the motive power for a dynamo during the evening is very conveniently combined with pumping water, cutting chaff, pulping roots, or sawing timber during the day. There are certain points to be considered in each individual case before deciding what method of producing power is best and most economical—such as cost of coal, coke, or paraffin oil delivered on the spot, if water power is available, and how far off, besides the position of the house itself, and also for how many months in the year it is usually occupied. Wind power for water-pumping purposes has of late come into use, chiefly owing to the great improvements in windmills, which are now of neat construction, and combine low first cost with slight expense for attention, while as a source of power the economy of its use is no less than 1½ times that of a steam pump, besides obviating the first cost of a boiler, and also doing away with the necessity for skilled attendance. The extra expense required is the storage, which should not be less than at least three days' average daily consumption, to allow for possible calm days, or when the wind velocity is less than six miles an hour. The author, by the kindness of Mr. Alwyn, of the Brush Company, has been able to lay before you a description of the plant and apparatus erected and used by Mr. H. C. Brush at his private house in Cleveland, U.S.A., where a 60ft. windmill is used for driving a dynamo, the current from which is stored in no less than 12 batteries of 34 cells each, each cell of 100 ampere-hours' capacity, giving a total of 40,800 ampere-hours stored. The author has made enquiries of several manufacturers of windmills, as also of electrical contractors, and can only discover one installation in England in which wind power has been used for electric light. In this solitary case the windmill was used to charge storage batteries, the mill being usually run during the day, driving a shunt-wound dynamo. This most interesting installation, which was at Messrs. Carwardine's Flour Mill in the City-road, in so far as wind power is concerned, is now disused, and gas has taken the place of the wind, and a gas-engine now charges the storage cells, and also works the mill.

Water power, if the supply is pretty constant, and not liable to dwindle to zero in summer, with a corresponding maximum of flood in winter, is the most convenient and economical source of power, though seldom available in this country; a notable example of its application is at the new installation at Chatsworth.

Steam power is more employed than any other, because cheap water power is comparatively rare; in nearly every available stream the milling rights are of considerable value, and the power is chiefly taken up by flour mills or other long-established businesses. Steam power plant is comparatively cheap to buy, and can be made portable at a slight increased cost. There is no necessity to discuss its application in detail, as it is so universal.

Gas power, by which is meant gas being generated, stored, and used on the premises, and not supplied by a public company, has made considerable strides in the last few years, chiefly owing to Mr. R. Dowson's inventions and improvements.

Oil-engines, in which the oil is admitted drop by drop into a "vapouriser," and then mixed with air and exploded, have lately come considerably to the front, being much simplified and improved in construction and economy of running. In a report by Mr. Worby Beaumont on some trials with a 6-h.p. actual engine in May, 1893, the cost with oil at 4d. per gallon came out as ·348d. per indicated horse-power at full load. As a fuel, oil at the present time seems likely to become extensively used.

In nearly all country houses where electric power is in use, motors of small powers can be conveniently used, and a move in this direction is slowly being made. Electric lifts can be used for hauling coal or visitors' luggage to the top of the house, or even for the speedy delivery of the dinner from the kitchen. Boot-brushing machines, knife cleaners, churns, are easily worked by a small ¼-h.p. motor, not to mention the convenience of larger sizes for raising water or pumping sewage. In the house, again, electricity is beginning to be used for cooking and heating, and in the latter respect, in particular, is of great use as affording a ready and convenient method of warming, and thereby airing rooms. Messrs. Crompton and Co. have lately made stoves a special line, and are now making cooking stoves of a size capable of preparing food for a household; they are built like gas stoves, but work with the natural advantage of absence of smell of gas and necessity for ventilation. For country house electric lighting purposes it is evident that some form of storage of power is necessary, because of the intermittent use of current.

THE DESIGN OF AN INSTALLATION.

An important point which should always be carefully studied when designing a country house installation, is the amount of current usually required, as well as what the maximum demand will be, for the local conditions should be carefully considered, as no two houses are alike in these particulars. In the case of a large installation, which becomes almost a so called central station, it may even be more economical to run direct during the time of heavy load, and use a small battery for the day load, and for after 12 p.m., while in a smaller installation it may be found better to lay down a smaller generative plant, and rely chiefly on the battery, charging up during the hours of the day, and thereby running at the maximum efficiency of the power plant. It is always best to have too large rather than too small a battery, for then in case of accident to the power plant we have spare storage to take its place, at all events, for the necessary lights. One of the most difficult problems that a consulting engineer is called upon to solve, and which requires most careful consideration, is the redesigning or arranging small installations originally carried out by contractors whose one aim seems to have been to lay down as much plant and apparatus as possible, without any consideration of local requirements. The author does not wish to suggest that this practice is universal, and no doubt much work, when originally carried out, was at the time considered to have been carefully planned; but of late special attention has been given to cost of running, and from experience gained by the pioneer installations, even a contractor, without a consulting engineer's knowledge to help him, should be able to design the proportions of generative plant and storage to the best advantage.

ANNUAL COST.

In comparing the annual expense of various small installations, stress is often laid on the cost per unit generated or supplied to the lamps, as if a house of some 200 lights could be compared with a central station with 20,000 lamps connected to its mains. To refer to a recent paper by Mr. Gisbert Kapp, it will be seen that the cost per unit generated, including repairs and 8 per cent. for interest and depreciation, for five private houses of from 70 to 720 lamps will average rather over 14d. (14·079). When, however, we analyse the results from installations of from 1,000 lamps and upwards where the current is in use daily, and for commercial purposes, we find that the cost falls at once to 3d. or even under. The author has obtained some figures of annual cost from three typical installations, when the power is in one case water, and in the other two steam, which are as follows:

CASE I.—WATER POWER.

Here the whole of the work required for damming the river and regulating the level of the water was already done, and the wheel existed, so the only expense incurred in installing the electric light consisted in arranging suitable gear and erecting counter-shafting for obtaining the necessary high speed for the dynamos. These are two in number, each of 120 amperes, 145 volts, and driven off the countershaft already mentioned. The current is conducted at a potential of from 110 to 140 volts, a distance of about a mile to the accumulators at the house, from whence it is distributed by an ordinary arrangement of regulating switches. Part of this main cable is of bare wire, supported on ordinary telegraph-pattern insulators fixed to wooden posts, and the last 300 yards is of insulated cable underground. The leakage on the bare portion of the cable in wet or snowy weather must be very high, and the greater part of the ground is liable to be flooded after every heavy rain. The storage battery consists of a set of 57 K-type E.P.S. cells, lately installed, and replacing 55 of L type. As the lights in the house and stables number about 200, on occasions when much light is needed one dynamo has to be run to supplement the storage.

This installation is particularly interesting as being now nine years old, and one of the comparatively few in England where water power is available; the original cost of the plant and apparatus, including wires and fittings, was over £3,000. It is not difficult to arrive at the total annual cost of production. Repairs and renewals to the dynamos, cables, fittings, not including interest and depreciation, have amounted on the average to 10·8 per cent. per annum on the prime cost; and the battery renewals, including the latest complete renewal of the entire

* Abstract of paper read before the Civil and Mechanical Engineers' Society.

Digitized by Google

battery, work out to 14·6 per cent. The labour bill cannot be put at more than 10s. per week, or £26 per annum, as the man in charged is not a skilled electrician, and has also to attend to the various agricultural machinery driven off the same waterwheel which works the dynamos. The units supplied to the lamps can only be guessed, but it is fair to take them as equal to those required by houses of equal size in London supplied by a public company, which amount to about 12 B.T.U. per lamp per annum, or for the 204 lights, 2,448 total units. Including interest and depreciation at 8 per cent. on the cost of the generating plant, cables, and wires, and adding the average cost of repairs, putting labour at only £26 and petty stores at £10, brings the total annual cost to €569, or 55·7d. per unit, or £2. 16s. per lamp per annum. And if looked at as purely "out-of-pocket" expense. the annual cost has actually averaged £369. The whole plant and apparatus is considered to be now in good order and condition.

CASE II.—STEAM POWER.

The power plant consists of a compound-wound dynamo, driven by a vertical single-cylinder steam-engine, the boiler being vertical and tubular, and the storage one set of 53 K-type cells. The number of lamps fixed is 340, of which 100 are usually burning every day; in addition to the lighting, the current is used to supply a motor about 400 yards away, which actuates a pump, and raises water to a high-level reservoir. The current required for this amounts to 2,000 units per annum. The annual costs are only available for two years, and work out as follows:

1892.	Total cost, including renewals, interest, and depreciation as before (8 per cent.)..	£478
	Which, assuming again 12 units per lamp fixed, gives 4,080, and plus the pumping, a total of 6,080, at a cost of..	17·9d.
	The out-of-pocket expenses were.....	£258
1893.	Total cost, calculated as before.....	£406
	The coal bill was fully 25 per cent. lower, owing to the units consumed being less in number; taking them at 10 instead of 12 gives the total units as 5,400, and the cost at (each)	18d.
	The out-of-pocket expenses were	£196

Note.—No spare plant. When all lights are on it is a strain on engine and boiler; they must be run at full load of 80 amperes, and assisted by the cells to give the 150 required, nor is even a spare armature available in case of a breakdown. The plant having only been in operation for two years is in good condition. The cells have lost a good deal of paste, and in future years the repairs to the cells will no doubt be costly, and the annual expense will then work out higher.

CASE III.—STEAM POWER.

Here we again have steam power, but of ample size to supply more than the total requirements of the house, without calling upon the battery, also of ample size. The generative plant consist of a compound engine and shunt-wound dynamo, the latter giving 120 amperes and 140 volts, while the battery consists, or rather consisted, of two sets of 32 L-plate cells, capable of 120 amperes discharge. The number of lights fixed is equal to 205 of 8 c.p., which at ·4 ampere each requires 82·0 amperes only. The drawback to the arrangement of power and storage units is that, except when charging both sets of batteries in parallel, the engine and dynamo can never be worked at more than half load; it would have been far better to have arranged the generative power capable of supplying 80 amperes as a maximum with 100 volts, which would have been ample for running direct, if required, or for charging one-half of the battery, would have been always running at practically full load with 60 amperes and 140 volts. The battery being so large could have been economically charged in alternate halves, while, if as arranged, both halves are charged in parallel, the generative plant will stand idle for fully four days a week in summer, or two at least in winter. It is true that the engineer's time is not required all or every day, and therefore is available for other work on the estate. The annual costs for three years are as follows:

1891.	Total cost, including interest and depreciation, etc., as before.....	£445
	Cost per unit, 12 units per lamp for 225 lamps fixed.....	39·4d.
	Out-of-pocket expenses were.....	£148
1892.	Total cost	£452
	Cost per unit	40·2d.
	Out-of-pocket expenses	£155
1893.	Total cost	£483
	Cost per unit.....	43d.
	Out-of-pocket expenses	£186

The reason of the great difference between the out-of-pocket expenses and the total cost is accounted for by the fact that at the present time one-half of the battery is on the rubbish heap, and the other half should by rights be there also, and so the author has divided the cost of the cells into three portions, and put down one to each year as, strictly speaking, due to debit. But to repeat such figures and facts are tedious and do no good; they are only given in this paper to emphasise what the author has already referred to above as showing how very expensive a lazy or incompetent man in charge will be, and also how the effect of bad arrangement to begin with bears its fruit in due season. In the first case brought before you this evening, the battery renewals have come out high, as there is no one on the premises who in the least understands treatment of storage cells, and in the last case a valuable battery by consistent neglect has been irretrievably ruined. In the second case, only two years' account being available, the cost per annum is very reasonable, and not above what a private house installation usually costs. It evidently is by far the best policy to arrange for the battery to be regularly inspected, not by the contractors who supply, but by the manufacturers, even if the cost of maintenance is as high as 10 per cent. per annum.

TRAMWAY TRACTION IN NEWCASTLE-UPON-TYNE.

REPORT BY THE BOROUGH ENGINEER.

We give below the report prepared by Mr. W. Geo. Laws, M.I.C.E. (city engineer of Newcastle-upon-Tyne), for the Town Council concerning three systems of tramway traction.

By a minute of May 21, 1894, you asked me to give you a report on the three systems of tramway working which you considered might be applicable in Newcastle—viz.: (*a*) the horse traction system; (*b*) the conduit electric system; (*c*) the cable system.

You advisedly excluded the overhead electric system, while the accumulator method has hitherto given such lamentable results that you thought it not worth consideration. You decided, in fact, that the three systems mentioned above only were in the running, an opinion which I fully endorse. I now submit the report, having condensed it as far as possible in the hope that, though much more might have been said on the subject, yet that all the chief points that should guide you in your decision have been touched upon.

(*a*) THE HORSE-TRACTION SYSTEM.

This is the system at present in use at Newcastle, and in many respects it fails to meet the public wants. The main facts of the Newcastle tramways are as follows:

The mileage open (single line) is	14 miles.
The length of route worked	9 miles.
The number of miles run, per annum	615,000
Passengers carried, per annum	3,890,000
Receipts per mile run	12·65d.
Expenses per mile run	11·25d.
Average total receipts are	£32,000
Average total expenses.....	£29,000

Number of cars, 34. Number of horses, 281.

The service of the chief lines of route is at 10-minute intervals to and from Scotswood, Gosforth, and Byker; 20-minute intervals to and from Elswick and Arthur's Hill; and at 40-minute intervals to and from Jesmond-road. The average speed of the cars (exclusive of waits at terminus) is five miles per hour. There is no attempt made to cultivate the short or immediate traffic, and no one who is in a hurry dreams of waiting for the cars. At present, anyone who has to go a mile can be pretty sure of walking it before a car passes him, and even up to 1½ miles he has an even chance of coming in first, and will certainly "save his distance." Thus, only the long-distance traffic is catered for, and the short 1d. fares are as far as possible discouraged. If the cars were run at intervals of five minutes or less, everyone could reckon on not having to wait longer on the average than 2½ minutes, and many more persons would use the cars for short distances. The invariable result in towns has been that quickening the service—that is, reducing the intervals between cars—has greatly increased the total number carried, and reduced slightly the average distance travelled. And those lines which have catered best for the short-distance riders have been most successful in reducing the expenses per car mile, which is the great secret of success in street tramways. Horse traction, therefore, must soon become a thing of the past, except in country districts and for feeder lines.

Every car requires four pair of horses to keep it running, and they must be fed; and in practice it is found that it is not possible to reduce the cost on the horse system below 10d. per car mile, which cost is not at all affected by the numbers carried, and varies only with the price of hay and corn.

(*b*) THE CONDUIT ELECTRIC SYSTEM.

This system has not as yet had an extensive trial in England, and, unfortunately, the limited experience obtained has not been very happy. Thus, at Blackpool, where a conduit system was laid, and promised well for a while, when taken over by the Corporation it gave so much trouble, owing to excessive leakage and deterioration of the apparatus, that for some time it has been worked by horses. One or two other small conduit systems in England have proved failures. There has, however, been an installation of the conduit system at Budapest, in Hungary, which has proved successful, both mechanically and commercially, and where the cost per car mile has been brought down so low as fairly to bring the system into the field as a strong competitor. It will be fair, therefore, to take the figures of this system, making such modifications as are rendered necessary by the different conditions of the case to reduce it to English standards. Thus, Pesth is specially favourable for electric traction, being practically flat. The chief streets are extremely wide, sometimes 150ft. and 200ft., and this allows of the tram lines being run outside of and parallel with the ordinary traffic, while leaving ample room for carriages and carts alongside the footwalks. In consequence of this peculiarity the speed of running is much greater than could safely be allowed in our narrow and crowded

Digitized by Google

streets. Labour in Pesth is one-third less than in England, while fuel is one-fifth more. The chief facts in Budapest are:

Mileage open (single line)		14 miles.
Length of route		7½ miles.
Miles run, per annum		1,437,000
Passengers carried		11,000,000
Receipts per car mile		11·86d.
Expenses per car mile		6·32d.
The cost per single mile of		
Construction	£12,000	
Equipment	2,750	
		£14,750

The service on the electric route is at intervals of 1½ minutes, and the average speed is 12 miles per hour—viz., 9·3 miles in the heart of the city, 11·16 in the residential parts, 15·5 in the suburbs. The cars are small, to seat 20 passengers only, but with wide platforms, on which many stand. They have no seats on top. The population of Budapest is 520,000, but as the tramways are laid in Pesth, probably 300,000 is a fair estimate of the population served. Buda, on the other side of the Danube is hilly, while Pesth is perfectly flat. The difficulty of working electric lines on any but very flat gradients has prevented the extension of the system into Buda, and the authorities are now enquiring into the possibility of introducing the cable system there. Commercially, the result in Pesth is that the shareholders have received dividends of 7 per cent. in 1892, and 8 per cent. in 1893, while a tax of 2 per cent. is paid to the authorities for the concession. On a total capital of £284,000 (which includes, however, some miles of steam lines), the earnings were, in 1892, £68,893, of which, after payment of expenses, about £24,100 was available as profit, and £17,500 was divided among the shareholders. For 1893 the figures were:

Capital expended	£284,000
Total earnings	81,330
Net earnings	32,452
Divided as profits	26,666

These figures have been taken from the officially published balance-sheets of the company.

There are some specialities of construction which must be noted as bearing on the applicability of such a system to English towns, and especially to Newcastle. For these particulars the committee is indebted to Mr. W. N. Colam, who visited Budapest in the course of business, with a view to see the details of a system that promised so well, and who has put the results of his investigations before you. The construction may be broadly described as the same as the cable system—viz., with a conduit underground to carry the moving power, but with this difference, that while in the cable system the conduit for the rope lies in the centre of the way between the rails, in the electric system it is placed under one rail. At first sight it would appear as if this was a distinct saving in first cost by avoiding the central slot rail; but the saving is more apparent than real, as the actual cost of the way is about £1,000 per mile more than in the central-slot system. Besides this, however, there are disadvantages as compared with the central slot which are very serious and more than counter-balance the saving of the central rail. The central slot is not subject to wear and tear from the flanges of the wheels since they do not run in it, and consequently there is no tendency to wear it down or widen it, and it remains permanently at its original width of ⅝in., and the edges remain unworn. With the conduit under one rail, on the other hand, the slot takes the flanges of the wheel and it is subject to rather heavy wear and the edges are rapidly rounded off and the slot widened. The width required to allow the electric "collector" to pass is larger than is needed for the cable "gripper," for while all the power of the gripper may be conveyed by a plate ½in. thick, the electric "collector," though thinner, has to be protected on each side by "insulators," and these again have to be defended from wear by iron plates on either side. The result of this is that the original width of the electric slot must be at least 1¼in. or 1⅓in., rather more than double that of the cable slot. As a matter of fact, Mr. Colam found that in Pesth the slot was in no case less than 1¼in. in width, while this had in many cases, and especially at curves, been enlarged by the wear of the wheel flanges to 2in. This very wide slot, which is tolerable in Pesth, where the ordinary traffic need not cross the tram lines except at a safe angle, would be a nuisance in our streets, where the horses wear caulkers, and where the ordinary cart and lorry traffic must work over the lines at all angles, while a bicycle wheel would drop through altogether with the risk of "short-circuiting" the conductors, and stopping the traffic on the line within that section. The electric system needs a quick means of getting at the underground conductors to remedy defects of insulation and for cleansing of the conduit, which is specially necessary to prevent accumulations of dirt or water, which at once stop the work by "short-circuiting." To provide this means of easily getting at the tube, two courses of brick in mortar are laid under the rails on the top of the concrete conduit, and when any stoppage occurs a rail is taken up, these bricks pulled out, and the necessary repairs done, after which the bricks and rails are replaced. This seems rather a clumsy way of working, and if it has often to be resorted to would become an intolerable nuisance in our crowded streets. It may answer in a town where the streets are so wide (as in Pesth) that the ordinary traffic has room to avoid the chasm laid open without being seriously inconvenienced, but with us, where every foot of the street width is used, and the ordinary traffic uses, and must use, the tram lines quite freely, such a system would be unworkable. There seems reason to fear also that the electric conduit, which seems to be specially susceptible to dirt even in a dry climate, would be more so in our wet and muggy weather, when the amount of mud that must pass through so wide a slot would cause constant trouble, and interruptions from that cause would be even more frequent. This seems to have actually been the case at Blackpool, and to have practically made the conduit system unworkable as first laid down, so much so that it is at present given up for horse traction, pending extensive alterations by which the Corporation hope to overcome the difficulties. Snow, too, has been found very difficult to deal with on the electric conduit, and has occasionally stopped the lines for days together. The use of loose brickwork for the rails to rest upon makes the Pesth road rather a flimsy one, and such as would not satisfy us here. It seems to be only tolerable where the street width allows the ordinary street traffic to avoid the tram lines.

There seems to be good reason to suppose that the very successful financial result in Pesth is due to local conditions and could not be realised in England—or at least in English towns. The chief reasons that would increase the expense of working per car mile in England are:

1. The cheaper labour obtainable abroad—viz., 33 per cent. cheaper for half-skilled labour, such as conductors, drivers, clerks, etc., and nearly 50 per cent. cheaper for cleaners, greasers, and the like.

2. The very high speeds allowed in the streets—viz., an average of 12 miles per hour, as against eight miles, the utmost hitherto allowed in English towns. This at once increases the car mileage and shows reduced cost.

3. The difficulty of applying any electric systems to towns where there are hills to surmount. The increase of power required to take an electric car up a moderate hill is out of all proportion to the work done. Thus, a car which would consume 10 e.h.p. on the level would require 28 e.h.p. to carry it up 1 in 20, and 36 e.h.p. on 1 in 10, the speed on 1 in 20 being also reduced 40 per cent., and on 1 in 10 by 66 per cent.; or, to put it in another way, to carry the same load at the same speed up 1 in 20 would require four times the power, and up 1 in 10, 11 times the power required on the level. This involves the further disadvantage that each car must carry motors powerful enough to surmount the steepest hill on the route, although they are useless dead-weight on the level. For instance, a car must carry motors in Clayton-street four times more powerful than necessary, in order that it might be able to crawl up Westgate-hill at one-third the speed. This is not very promising for electrical traction in such a town as Newcastle or Leeds, and yet engineers on both sides seem to be agreed as to the fact of the unsuitability of electric motors for even moderate gradients. They differ only in their estimate of the waste of power, but, taking the most sanguine figures, it is practically fatal to cheap transit.

4. The moister English climate is unfavourable to the rather delicate apparatus, and promotes leakage of energy by keeping the conductors damp, and would also presumably require even closer attention to keeping the tube clean. A piece of damp paper (such as we see too much of in the streets) would, if blown or dropped through the slot, and falling on the conductors, be enough to short-circuit them and stop all traffic on that particular section until its whereabouts was discovered and it was removed.

It is difficult to estimate the actual increase in cost per car mile for each of these items, except in the case of No. 1. Allowing for dearer labour and cheaper coal in England raises the car mile cost by ·75d.—viz., from 6·32d. to 7·07d. The difference produced by No. 2—that, is the lower working speed here—can only be inferred by working out the reduction in car-mile cost made by increasing the speed on the cable roads; but taken in this proportion would be about ·80d. The difference caused under No. 3—viz., the disadvantage on gradients—would depend greatly on the proportion of steep streets worked on the system. Assuming that in Newcastle the proportion of steep gradients is one-third of the whole, the total power required would be increased as 5 to 3, which would mean an addition of about ¾d. per car mile. Under No. 4—the influence of climate on the system—there is no means of making an estimate. It might be so great as to stop working altogether, as at Blackpool. Putting all these together, the probable cost is raised to 8·62d. per car mile, which corresponds pretty closely with American experience, where the best information that can be got puts the cost per car mile of electric traction at the best at 1½d. below horse traction, which brings it to 10½d. in America, where prices of labour are high. Assuming horse traction here, in Newcastle, to cost 10d. per car mile, which is about the figure, that would bring the electric system to 8·50d. as compared with 8·62d. as obtained above. There is one point which should not be forgotten in comparing the results at Pesth with those, say, in Edinburgh—viz., that the average fare per passenger is 1·4d. in Pesth, against 1·1d. in Edinburgh. To bring the fares there down to English standard would at once reduce their traffic receipts by £12,000, and take just 5 per cent. off the dividends earned. The fare system abroad is somewhat different to that prevailing in England. We stop to pick up at any point where a passenger may call; on the Continent the "stations" are fixed, and cars do not stop between. In Pesth they have also a plan of using fare-books, by which considerable saving is effected. Thus, though their lowest single fare is 2d., return and season tickets bring down the average fare to rather under 1½d.

(c) Cable Traction System.

In this case one has surer ground to work on, because the system has been extensively tried both in America, England, and elsewhere, so that the costs both of construction and working are pretty well known. It is not necessary to describe the system in detail, further than to remind you that the power in this case is

Digitized by Google

applied by means of an endless rope travelling at a fixed speed in a conduit very similar in shape and size to that required by the conduit electric system, but placed in the centre between the two running rails, and forming practically a third rail, with a narrow slot through which the "gripper" takes hold of the cable below. These cables, which run up one line and down the other, are drawn at a fixed speed from central stations placed in the most convenient spots obtainable. This speed in England is limited to eight miles per hour, as at Brixton, but in Edinburgh was further limited by the local authority to six miles. It is found by experience that the limit of length of cable which can be economically worked from one engine house is about six miles—that is, three miles out and three home again—so that an engine station placed centrally in a town can work any route which lies within a radius of about three miles from that centre; and, of course, any number of cables can be worked from the central engine-house by providing a like number of driving drums and engines of sufficient power. As the car when travelling is attached by the gripper to the cable, it travels at the same speed, less any slip in the gripper; and in going down hill it also travels with the cable, and so long as the gripper remains tight cannot run away. This is one of the peculiar advantages of this system, that so long as the machinery is in good order, the car is under complete control. The power absorbed in moving the rope is, of course, constant, and every additional car put on only consumes the power required to move its own load, and this applies equally to level ground and to gradients, since the descending cars always balance within a small fraction those ascending; in fact, the only loss in that respect is the small amount due to the "friction" of the car wheels and axles, and to the "stiction" of the wheels on the rails. As no part of the power required to drive the car passes through the wheels and axles, these can be made as light as for horse cars, and the wear and tear on the rails is reduced to a minimum; whereas, in all systems electric, steam, or otherwise where the car is driven by a motor, not only is there a greater friction, causing greater wear of rails, but the wheels and axles must be heavier, and, in fact, the whole car must be made heavier to give sufficient adhesion for driving. As the cable travels at a fixed speed, the journey time of the car must always be less than that speed would allow, and, in fact, with a cable travelling at eight miles per hour the car will only average seven miles, or less. The special feature of the cable system, that every additional car put on only adds a few pounds of coal consumed at the engine-house, but does not increase the fixed charges, while it does not increase the car mileage, renders it specially applicable to a growing traffic and to the further development of traffic. The experience of Edinburgh has been that as soon as the receipts reached 1s. per car mile, it was policy to put on more cars, reducing the earnings, but also reducing the expenses in a greater ratio. Thus, when the line first started, the earnings were 1s. 5d. per car mile, and the expenses the same, leaving no profit. Now, by constantly adding cars the receipts have come down to 11d., and the expenses to under 7d., leaving 4d. per car mile of profit. When, as at Brixton, the traffic to be won is large, the results have been still more startling, the service having been quickened by adding cars till they now run at one-minute intervals, while the expenses have been reduced to something under 4d. per car mile. At Brixton, also, a further alteration has been made by reducing the fares to ½d. per half-mile, instead of 1d. per mile—that is, by catering for the short distance traffic. The experience of Birmingham, where four systems are at work under the same company, shows that cable is earning 6d. per car mile, steam nearly 4d., horses 1½d., electric (accumulator) losing 2d. The disadvantages of cable traction are:

1. The high cost of construction, which is about £10,000 per single mile—less, it is true, than electric conduit, but double that of horse lines. The cost of equipment, however, is only £1,000 per mile, as against £2,750 on the electric system. A cable car, complete, costs about £220, while an electric car costs about £700.

2. The central rail is a further interference with the streets, and with the ordinary street traffic. It is true that that has been minimised in the most modern construction; still, it is an interference, and nothing but the conviction that the advantages which the cable system offers to the public in the way of quick and cheap transit are so great, would have overcome my objection to it on that ground.

Some other objections have been raised, as, for instance, to the noise made by the rope running over the sheaves. These seem chiefly sentimental. It is difficult to understand how such a noise, if it exists, could be heard over the ordinary noise of the traffic in paved streets. In Edinburgh, where the ordinary street noise is less than usual, the cable is not audible except by stooping over the slot. At Brixton, where the ordinary traffic is much larger, the cable will be even less heard. The question has been asked of me why the construction of the cable road could not be cheapened by laying the tube or conduit under the one rail, as in the Budapest system, and so avoiding the objectionable third slot rail. The mechanical objection is at once apparent that the pull on the car would be all on one side, and would tend to twist it, wearing the wheel flanges and rails unduly, and giving the car a tendency to always take points and turn-outs on the side opposite to the pull. It has lately come to my knowledge that this system has been tried on the Lisbon tramways, where it failed for the very reasons given above, and gave so much trouble that it was in contemplation to reconstruct the line to get over the difficulty. Up to this time that has not yet been done, but the system has been definitely condemned. The Pesth experience affords a further reason for avoiding any system where the flange of the wheel travels in the slot, as the great wear which has taken place renders the slot wider and more dangerous every day. The figures of the cable system, applied to Newcastle, would come out as follows:

Cost of construction	£10,000 per mile.
Mileage worked (single) would be	24 miles.
Length of route	12 miles.
Number of miles run, per annum	1,500,000
Number of passengers carried, probably	10,000,000
Interval between cars	5 minutes.
Probable earnings, per car mile	8·25d.
Probable expenses, per car mile	4·5d.
Number of cars running	50
Average fare per passenger	1¼d.
Average length of journey	1¼ miles.

These figures are based on the working of the Edinburgh lines, and the probable number of passengers is estimated from the average of six large towns, including Newcastle. This average shows 38 times the population carried every year, but the figures given above are based on 50 times only.

Having now laid the chief points of the three possible systems of tramway traction before you, it may be expected that I should express some opinion as to which seems to promise the best results for the town and the public. It seems unnecessary to further consider horse traction at all. It has done fairly well in the past, and has served its purpose, and become obsolete as not meeting the public wants. The town, in fact, has outgrown it, and wants something more modern and offering greater facilities both in speed, accommodation, and cheapness; and, indeed, the object for which your committee was appointed was to find some better system of mechanical traction. This reduces the matter, then, to a choice between the electric conduit and cable traction systems, and whichever of these affords the greatest advantages in cheapness of construction, cheapness of working, convenience of service, and cheapness of fares should be that you will choose. There are two or three general considerations that seem worth formulating before going further, as they bear directly on the question—viz.:

(*a*) Whatever system is chosen, the capital cost of constructing the lines must be undertaken by the Corporation. This is the only method by which they will retain the control of their own streets, and by which they are not left at the mercy of their lessees at the end of the lease. They might otherwise find themselves compelled either to re-let the lines to tenants for whom they did not care, and on terms they did not think favourable, or to purchase the undertaking at a cost far beyond its real value, because they, the Corporation, would have to provide for the carrying on of the service immediately it was given up by the lessees. The method provided in the Tramway Act for acquiring the undertaking by arbitration is expensive and uncertain, and where it has been exercised, corporations have generally discovered that they have had to pay more heavily than if they had laid out their own money to begin with.

(*b*) The system adopted must be one that is commercially successful, so that there is no need to subsidise it from the rates.

(*c*) It should be so successful as not only to pay proper interest on the capital expended, and to redeem that capital during the period of the lease, but also to afford a fair margin of profit on the capital laid out by the lessees themselves. It is clear that the only real security for the payment of interest and redemption on capital, is that it shall be the interest of the lessees to hold the lines as long as possible, and that can only be where they get a good return for their money.

(*d*) The above results should be realised with so low a scale of fares as to make the tramways a real boon to the public using them.

(*e*) The mode of construction adopted should interfere as little as possible with the use of the streets for ordinary traffic.

Bearing these points in mind, it seems to me that as to cost of construction there is not much to choose between the two systems. The electric, apparently, has cost more in Pesth, in spite of cheap labour; but there seems no real reason why it should. The work to be done is practically the same—viz, to lay a conduit for the conductors or cable and the rails. There should be little or no difference in first cost. The cost of equipment is certainly much larger for electric haulage, and must necessarily be so, since motor cars cost about three times as much as cable cars, but this is a matter more for the lessees than the Corporation, as equipment is a lessee's cost. It is only important as affecting the amount of money that must be earned to pay interest on capital. Cost of working is the next consideration, and here the advantage is in favour of cable haulage. Budapest shows a very good result; but, as has been shown, this result has not been realised in America, and is not likely to be realised here, while, on the other hand, both English, American, and European experience has confirmed the low cost per car mile of cable traction, and the fact that the larger the mileage run the less the average cost. The cost of cable haulage in America on the larger lines is put at under 5d. per car mile, which, allowing for American prices, would correspond to about 4d. here. Where it has had a favourable chance, as at Brixton, that result has already been realised, and on popular fares, too. Applying Edinburgh results to Budapest figures shows that with such a service—viz., 1¼ minutes, and carrying the same number of passengers—the cable would be worked even below 4d., thus beating electricity on its own ground. Here there is less difference in convenience of service, for the Budapest service is excellent—viz., 1¼ minutes between cars, and high speed—which, however, could not be allowed in English towns; but beyond this there is the great difference that while electricity is heavily handicapped by even moderate gradients, and must either go at a slow speed or wastefully use energy—in

Digitized by Google

fact, must either "crawl" or "cost." Cable, on the other hand, takes no account of hills as steep as Westgate, but goes at the same even speed whether on the level or up or down gradients as steep as 1 in 11. This is a very great point, and, to my mind, points unmistakeably to the cable as the only system really suited to Newcastle. Cheapness of fares has already been touched upon, and here again the cable has the advantage, not only in running at cheapest fares already, but as affording the prospect of still further reduction as traffic increases. In the latter quality it stands alone as the one system where it is to the interest of the lessee to reduce fares. All the others have a minimum below which the cost cannot be reduced, no matter how many cars are run or how many persons travel.

Finally, there is a fair prospect of the Corporation being recouped for their outlay and getting interest and redemption duly paid to them. The figures on page 13 are the best warrant for this. They have been studiously kept moderate and are based on the average of results obtained in other similar towns, to which the lowest scale of fares has been applied. They show that to pay interest and redemption on capital will require 2½d. per car mile, and that 4½d. will pay working expenses, so that if the tramways earn 7d. per car mile the Corporation is secure.

It seems to me that the cable system is on all counts the most suitable for Newcastle, and, further, that it is a safe investment for the Corporation, and beyond that a reasonably promising speculation for the promoters.

BUSINESS NOTES.

Derby.—The Town Council have decided to light the baths by electricity.

Norwich.—The electric light is to be installed in the Norfolk and Norwich Library.

Great Northern Telegraph Company.—For the month of May the receipts were £22,800.

Worcester.—The question of the electric lighting of the Victoria Institute is under consideration.

Western and Brazilian Telegraph Company.—The receipts for the week ended June 1 were £2,637.

Brechin.—The Police Commission intend to apply for a provisional electric lighting order for Brechin.

Removal.—Messrs. Lowdon Bros. have removed to the Temple Electric Works, 37, North Tay-street, Dundee.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 3rd inst. amounted to £830.

Tenders for Coventry.—The Town Council invite tenders by the 13th inst. for the erection of an electric light station.

Blackpool.—The Methodist Free Church in Adelaide-street has been enlarged, and the electric light has been introduced.

Tenders for Stores.—The Caledonian Railway Company invite by the 18th inst. tenders for the supply of telegraph and electrical appliances.

Dewsbury.—Considerable progress has been made with the construction of the engine-house, etc., for the Corporation electric light station.

Eastern Telegraph Company.—The receipts for the month of May were £54,846, as against £57,946 for the corresponding period of 1893.

City of London.—The Library Committee of the Corporation recommend the lighting of a portion of the Records Chamber with the electric light.

Burton.—Messrs. Hewes and Geary, of Church Gresley and Coalville have secured the contract for the electric lighting of the Cadley Hill Colliery.

West India and Panama Telegraph Company.—The receipts for the two weeks ended May 31 were £1,233 less than for the corresponding period of 1893.

Eastern Extension Telegraph Company.—For the month of May the receipts show a decrease of £1,435 as compared with the corresponding period of 1893.

Appointment Open.—As will be seen from our advertisement columns, a competent assistant electrician to chief engineer of central lighting station in British Guiana is required.

Edinburgh.—The Town Council have authorised the resident electrical engineer to go to London from time to time during this month to be present at tests of the electric lighting plant.

Preston Gas and Electric Lighting Bill.—This Bill, to which we referred in our last issue, was approved, with certain conditions, on Tuesday by a Select Committee of the House of Commons.

Batley Carr.—Messrs. Alfred Hill and Sons, of Batley, have instructed Mr. A. Richmond Turner, of Dewsbury, to put in an installation to light the whole of their premises with the electric light.

Dudley.—The Street and Gas Committee have recommended the Town Council to grant Mr. F. W. Cook, of High-street, permission to lay wires for electric lighting under a portion of King-street.

Reading.—An arcade and shops are being erected by Mr. C. Fidler which will be lighted by electricity. The installation has been entrusted to Messrs. T. C. Williams and Son, London-street, Reading.

Weston-super-Mare.—An engineer is to be chosen by the Electric Lighting Committee, at a fee of 50 guineas, to report on the questions of electric lighting, electric tramways, and refuse destructors.

Cowper Coles Galvanising Syndicate, Limited.—This Company has been registered, with a capital of £2,000 in £1 shares, to carry on business as electrical engineers, manufacturing chemists, etc.

Burnley.—It is announced that the firm of Messrs. Driver and Co., organ builders, of Hammerton-street, are the first to apply electrical energy locally as a motive power for the driving of wood-working machinery.

E. Wallace and Co., Limited.—This Company has been registered, with a capital of £1,000 in £1 shares, to act as agents for manufacturers of all kinds of goods; in particular of chemical, mechanical, or electrical goods and appliances.

Change of Address.—The St. Martin's Electrical Manufacturing Company, Limited, during the extension of their business premises, have taken offices at 6, Adam-street, Adelphi, Strand, where all communications should be addressed.

Glasgow.—The Clyde Navigation Trust have decided to make the buildings for the hydraulic installation at Cessnock Dock large enough to afford space for electric lighting plant, should the Trustees decide to light the dock with electricity.

Battersea.—The Battersea Vestry have referred to the Electric Lighting Committee a motion by Mr. C. Marson, that "considering the great expense of the horses of this Vestry, the Vestry is of opinion that electric motors be used in place of horses."

Telegraph Manufacturing Company, Limited.—The annual ordinary meeting of the shareholders of this Company was held on the 4th inst., and the same dividend as last year was declared—viz., 5 per cent., and in addition a bonus of 2½ per cent.

Hotel-Lighting.—Messrs. Rashleigh Phipps and Co., of 102, Oxford-street, have received the contract for the lighting of the Norfolk Hotel, Surrey-street, Strand, for 425 lights of 16 c.p. The work has to be finished in the short space of four weeks.

St. Austell.—In the House of Commons on Wednesday, the Bill confirming the provisional order of the Board of Trade conferring electric lighting powers on Veale and Co, Limited, in regard to St. Austell, was ordered to be read a third time.

Yeadon.—The Board of Trade Provisional Order Bill, authorising the Yeadon Local Board to make electricity and to supply the current to consumers by meter, has passed the Examiner in the House of Lords, and has been ordered to be reported for second reading.

Balruddery.—The starting of the new organ at Balruddery by Dr. Peace, of Glasgow, will take place on Saturday. Mr. Hope Jones will be present. This organ is a reconstruction on the Hope Jones electric system of an organ of about 25 stops, besides couplers.

West Hartlepool.—The Electric Lighting Provisional Order (No. 1) Bill has been read in the House of Commons a third time and passed, subject to the Royal assent. Its object is to confirm a provisional order made by the Board of Trade under the Electric Lighting Acts.

Sunderland.—The Corporation have received a report from Prof. Kennedy on the proposal to light the town electrically. He estimates the cost of arc lighting at £1,500 a year, or £550 more than gas lighting, but the amount of illumination would be 20 times greater.

Cardiff.—The Property and Market Committee of the Town Council have decided, since the electric light will soon be installed, to have the light in the market and Town Hall. The committee have decided to ask the borough engineer to formulate a report upon the matter.

Elieson Electrical Switch, Limited.—This Company has been registered, with a capital of £5,000 in £1 shares, to acquire, develop, and turn to account the patent rights for Great Britain and Ireland and the English colonies relating to improvements in electric switches or circuit-breakers.

Rawtenstall.—The town clerk's office, the borough surveyor's office, the central fire station, Lord-street, Rawtenstall, and the police station, have been connected with the National telephone system, so that communication now exists between those offices and all parts of the country.

Aberdare.—The Board of Trade Provisional Order Bill, empowering Messrs. J. C. Howell, Limited, to make and supply electricity through mains in Aberdare, has passed the Examiner on Standing Orders in the House of Lords, and has been ordered to be reported for second reading.

Telpher Cable and Cliff Railway Syndicate, Limited.—This Company has been registered with a capital of £6,000 in £10 shares, to acquire the concession granted to Mr. W. J. Brewer, C.E., authorising the construction of a cable across the Dyke at Brighton and a cliff railway to the Punch Bowl.

St. Pancras.—The Vestry have decided to reduce the price of current for public street lighting from 6d. to 5d. per unit after Michaelmas quarter next. The tender of Messrs. Kelly Bros., of Liverpool, for the erection of the new electric station buildings in King's-road, at £6,729. 13s. 6d., has been accepted.

City and South London Railway.—The receipts of the Company for the week ended June 3 were £869, against £914 for the same period last year, or a decrease of £45. The total receipts for the first half-year of 1894 show an increase of £519 compared with those for the corresponding period of 1893.

Bristol.—University College is shortly to be lighted by electricity. The installation will consist of a dynamo and 200 incandescent lamps. The contract has been let to Messrs. F. W. Ball

Digitized by Google

and Co., of Unity-street, Bristol, who have carried out similar work at the Cathedral, the Council House, and other buildings.

Leeds.—Leeds Parish Church is to be lighted by electricity. The plans and specifications have been prepared by Messrs. Shepherd and Watney, Albion-street, and the work will be carried out under their supervision by Messrs. Laing, Wharton, and Down, whose tender has been accepted. The total cost will be about £500.

Coventry.—It is reported that a start has been made towards getting the Coventry and district tramways in working order. The Electric and General Contract Corporation, Limited, have accepted the tender of Mr. Charles Haywood, jun., of 23, Gosford-street, Coventry, for the erection of a generating station and depôt at Foleshill.

Montrose.—Last week the Montrose Town Council visited Kinnaber Waterworks and opened an installation of the electric light there. The power is obtained by means of a water motor driven by the surplus water, and the whole of the extensive works, together with the engineer's residence and outhouses, have been lighted.

Binns's Gas and Oil Engine Company, Limited.—This Company has been registered with a capital of £2,000 in £1 shares. Its object is to acquire as a going concern the business hitherto carried on by Binns and Co. at Halifax, Yorkshire, and to carry on business as gas and mechanical engineers, ironfounders, electrical engineers, etc.

Aberdeen.—The Forsyth Hotel, Aberdeen, has been fitted with the electric light. The installation, which is the largest which has yet been made in connection with the Corporation, consists of over 200 lamps of 16 c.p. each. The work was carried out by Mr. A. G. Emslie, plumber, Rose-street, and Mr. M. Walker acted as consulting engineer.

Sheffield.—The Sheffield Electric Light and Power Company have commenced the work of laying underground mains westward. The work has been started at the monolith, up to which point the mains have already been laid, but work in addition is to be commenced at Ranmoor and in Division-street, so that operations may be completed as soon as possible.

Hull.—The Corporation during the past year have paid on account of electric lighting a sum of £16,938. 18s., making the total capital expenditure £35,153. 16s. On revenue account the adverse balance of £267. 1s. 1d., which was brought forward in last year's account, has been increased, and amounts to £1,080. 16s. 1d., which will be met by the amounts due from users.

Sutton.—The Local Board have received a letter from the Hove Electric Lighting Company, Limited, addressed to Mr. R. W. Wotton, as to Messrs. Crompton and Co. taking up the electric lighting of the district on such terms as to relieve the ratepayers from any expenditure, and have instructed the clerk to communicate with Messrs. Crompton and Co. upon the subject.

Newcastle-on-Tyne.—At Tuesday's meeting of the Town Council, Mr. Chapman presented the report of the special committee appointed to consider the desirability of the Corporation undertaking the provision of electricity in the city. The report is in favour of the Corporation undertaking this work, and we gave the substance of it in our last issue. The report was received.

Tenders for Aberdeen.—As notified in our advertisement columns, the President and Governors of Robert Gordon's College in Aberdeen are prepared to receive tenders for the following works—namely, (1) the supply of materials and the wiring of Robert Gordon's College; (2) the supply of two 1-h.p. electric motors; (3) the supply of materials and the wiring of Gray's School of Art, Aberdeen.

Wakefield.—The Wakefield Corporation Electric Lighting Bill, asking for leave to bring in a Bill for supplying the city with electric light, although later than the time allowed by the standing orders, has come before the Earl of Morley's Committtee on Standing Orders at the House of Lords. After hearing the explanation of the agents for the promoters, their lordships decided to dispense with the Standing Orders.

Electric and General Investment Company, Limited.—The directors on Monday decided to recommend to the shareholders the payment of a further dividend upon the ordinary shares at the rate of 40 per cent. per annum for the six months ended May 31 last (making, with the interim dividend of 10 per cent. already paid, 25 per cent. for the year), and a dividend on the founders' shares of £30 per share for the year.

Tenders for Newcastle-upon-Tyne.—Tenders are invited for telephonic apparatus for communication with the workhouse, for the Guardians. Forms of tender will be supplied at the clerk's office, where specifications and conditions may be seen. Tenders, endorsed "Telephones," must be sent to Mr. John W. Gibson, clerk to the Guardians, Union Offices, Pilgrim-street, Newcastle upon-Tyne, by 12 noon on 22nd inst.

Plymouth.—The Board of Trade Provisional Order Bill empowering the Corporation to generate electricity and supply the current through mains by meter to consumers, has passed the Examiner in the House of Lords on Standing Orders, and has been ordered to be reported for second reading. The mains are to be laid within two years of the passing of the Act in George-street, Bedford-street, and Old Town-street.

West Hartlepool.—At the monthly meeting of the Town Council, with regard to the proposal of the electric tramways company to arrange for lighting of the borough by electricity, Councillor Macfarlane suggested that the matter be confined, for the present, to the running of the tramways. Upon the recommendation of the Works Committee, the agreement with the tramways company was ordered to be sealed.

Bromley.—The Electric Lighting Committee of the Local Board have discussed the question of electric lighting in connection with the suggestion of the Beckenham Local Board that an electric lighting scheme should be worked jointly by the two Boards for the supply of Bromley and Beckenham. Further consideration has been adjourned by the Local Board for more enquiries to be made as to the feasibility of the scheme for a joint station.

The C.C. Concentric System.—Mr. H. T. Barnett, of the London Electrical Goods Agency, 53, Victoria-street, Westminster, recently appointed agent for the Southern district for Messrs. Mavor and Coulson, announces that that firm has now wired the offices of the agency on their C.C. concentric system. The various essential parts are supplied separately, and may be used by any contractor in conjunction with any form of concentric cable.

Glasgow.—On Sunday evening the electric light was used for the first time in St. Bride's Church, Kelvinside. The supply is taken from the mains of the Kelvinside Electricity Company. The contract was carried out by Messrs Claud Hamilton, Limited, to the plans and specifications of Mr. W. Elsdon Dew, resident engineer to the supply company. It is understood that other churches in the district are proposing to adopt the electric light.

Business Change.—Messrs. Binko and Co., of 34, Leadenhall-street, have purchased the goodwill and stock of the firm of Messrs. Ridsdale and Co., 54, Minories, nautical lamp and lantern manufacturers, ships' brassfounders, etc., subsequently carried on by Mr. H. G. Spurgin. They have added this business to their business of manufacturers of electrical supplies for ships' use and domestic purposes, consisting of electric light, bells, telephones, signalling, and other appliances.

Chelmsford.—The electric lighting company have commenced the work of placing the wires underground between the stone bridge and the Red Cow Inn. The electric fire-alarm calls have now been fixed by Messrs. T. H. P. Dennis and Co. at the price of £51. 10s. 8d. A committee of the Town Council is considering the advisability of allowing a telephone company to establish an exchange at Chelmsford in connection with the Government trunk line between Norwich and London.

Ravensthorpe.—The electric light installation at the Self-Help Stores is nearly completed. It comprises externally 18 arc lamps. In the interior of the premises arc lamps have also been fixed. In addition to these, there will be a total of 102 incandescent lights spread about the premises. The entire cost will be a little over £600, including a new engine-house, engine, and dynamo. Messrs. Ullathorne and Hartley, electrical engineers, of Bradford and Halifax, have been entrusted with the work.

Trawden.—The Local Board have received a deputation representing manufacturing firms in regard to the gas supply. Mr. Chester spoke of the serious inconvenience which the manufacturers as well as the weavers were put to during the winter months. They must either have an increased supply of gas or adopt the electric light. A resolution was passed by the Local Board that the clerk should write to the clerk of the Colne Local Board asking them to receive a deputation from Trawden.

The "Aetna" Blow Lamp.—A circular has reached us from Messrs. Moeller and Condrup, of 78, Fore-street, E.C., in reference to the "Aetna" paraffin blow lamp. This apparatus, which the firm states will be invaluable to electricians, instrument-makers, and plumbers, will bring a copper rod to welding heat in a minute, and two copper wires can be joined simply by holding them together in the flame. The firm deal in other types of lamps and stoves, which are mentioned in the circular in question.

Tenders for Oswestry.—Tenders are invited for the supply of engines, boilers, dynamos, switchboard, cables, and conduits for a central station and installation at Oswestry, Salop, for the Oswestry Electric Lighting and Power Company, Limited. Forms of tender and copies of specification, etc., can be obtained from Mr. W. W. Coulson, secretary of the company, Oswestry, Salop, upon payment of £1. 1s., which will be returned on receipt from the payor of a *bonâ fide* tender. Tenders to be sent on or before 16th inst. to the secretary.

Tenders for Mansfield.—Tenders are invited for the erection of a line of poles and overhead wires for the automatic indicating apparatus and telephones between the Rainworth pumping station and the waterworks manager's office at the gasworks, Mansfield, for the Waterworks Committee of the Mansfield Corporation. Plans and specifications may be seen at the office of Mr. George Hodson, M.I.C.E., Bank-chambers, Loughborough. Tenders to be delivered to Mr. R. J. Parsons, town clerk, Town Clerk's Office, Mansfield, by 12th inst.

Hastings.—The secretary of the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, has given formal notice, in accordance with the requirements of Section 14 of the company's provisional order, of the intention of the company to extend their mains. The whole of the mains were specified to be wrought-iron, lap-welded, screwed pipes, to be laid under the pavements where possible, about 12in. below the surface, with cast-iron inspection-boxes, and separate frame and pavement covers at about 40 yards apart were required. The formal approval of the Council has been given to the works.

Greenock.—On Tuesday, at the Town Council meeting, a report was considered from the Town Works Committee on the question of improving the lighting of the Town Hall by the introduction of the Sun burner, fitted with Soleil lamp clusters and reflectors. This report was moved by Mr. Peden. Bailie Cluckie was of opinion that before proceeding with the work they should ascertain the cost of introducing the electric light into the Town Hall. Mr. Hair remarked that, in the face of the fact that the Gas Trust

Digitized by Google

was £75,000 in debt, it would be unwise to have the electric light. The report was after further discussion adopted.

Belfast.—The Town Council have adopted the report of the Electric Committee. It stated that considerable progress has been made with the laying of mains, and that tenders for the erection of the central station had been advertised for. The price to be charged for electricity as fixed by the provisional order is not to exceed 8d. per unit, and the committee propose to charge 7d. per unit, with meter rent varying from 2s. 6d. up to 15s. per quarter, according to the capacity of the meter. The committee have accepted the tender of Messrs. M'Laughlin and Harvey, for the erection of the new central electric lighting station in Chapel-lane.

"Slashed" Shell Reflector.—This type of reflector, which has been brought out by Messrs. Faraday and Son, has been designed for lighting a reception-room from the walls in a soft and agreeable manner, chiefly by means of reflected light. The shell is made in hammered brass, finished either in silver, bronze, or gold colour. The lamp bulb is entirely screened from the eye, the light being strongly reflected from the inner plated surface on the walls and ceiling. The piercing or slashing of the shell in the interstices between the ribs is filled with tortoiseshell, talc, or other translucent medium, so that the sombre effect of an opaque reflector is obviated.

Debt for Current.—Last week, at the Guildhall, the United States Land and Investment Company were summoned by the City of London Electric Light Company for the non-payment of £5. 9s. 7d., for the supply of electric current and rental of meter. Mr. G. Kebble, who appeared in support, said this was the first summons under the Electric Lighting Act, and he asked that the order be made with solicitor's costs, as there would be considerable difficulties in the event of non-payments by persons to whom the current was supplied. There was no appearance on behalf of the defendant company, and the Alderman made the order for £5. 9s. 7d. and a guinea costs.

Dundee.—The Finance Committee of the Town Council have been considering the accounts for the past year. At the beginning of last year it was estimated that the expenditure in the electricity department would amount to £3,798. 10s 2d., whereas the actual expenditure was £4,532. 19s. 1d., being a difference of £734. 8s. 11d. The income from electricity was estimated at £2,000, and for meter rents at £35, or a total of £2,035; the actual income being £2,556. 14s. 10d. and £92. 6s. 8d.—total, £2,649. 1s. 6d.—a surplus of £614. 1s. 6d. For the current year the income estimates are: for electricity £3,200, and for meter rents £120, being a total of £3,320. The expenditure is expected to be £5,362. 6s 7d. The estimated deficiency for the year ending April 30 next is £320. 14s. 10d. The price is to be maintained at 5d. per unit.

New Electrical Works at Wolverhampton.—The Public Works Committee of the Town Council have passed the plans for the new works to be erected by Messrs. T. Parker, Limited, on Wednesfield-road. The works are to be of a most extensive character, and will cover four to five acres of ground. The site is immediately opposite the Midland goods station on the Wednesfield-road, and the Midland Railway Company have undertaken to form a siding into the works. The first section of the new works, which will be capable of considerable extension, will consist of a workshop 150ft. by 150ft. In addition to this there will be a foundry, the dimensions of the latter being 120ft. by 40ft, and pattern shops 80ft. by 40ft. Commodious offices will be provided, and these will be uniform in style and design, and in proportion to the works. The architect is Mr. A. P. Brevitt, who has had experience in designing electrical works in provincial towns.

Advance in Quotations.—"Just a week ago," says the *Financial Times* of Saturday, "we referred to the advance which had taken place in the quotations for the stocks of the City and South London Railway Company. Since then there has been a further upward movement, particularly in the price of the 4 per cent. debenture stock, which has risen 5 points to 120. At this price the yield to an investor is only 3½ per cent. The total loan capital authorised is £475,000, and of this there has been issued £95,300 in 5 per cent. debentures, and £97,130 in 4 per cent. debenture stock. The annual interest on these two is a little over £8,600, whereas the net receipts for 1893 were over £16,000, as compared with £13,700 in 1892. Of the 4 per cent. stock, £37,600 was issued in exchange for 5 per cent. debentures, £29,530 for cash, and the balance of £30,000 as security for a temporary loan of £22,000. The two former amounts only are included in the quotation in the official list."

Swan United Electric Light Company.—An extraordinary general meeting of the Swan United Electric Light Company, Limited, will be held at the Cannon-street Hotel, Cannon-street, on Thursday, the 14th inst., at 12 noon, to consider and, if approved, to pass the following resolution, which, if passed by the required majority, will be submitted to a second meeting to be hereafter convened for confirmation as a special resolution—viz.: "That the Swan United Electric Light Company, Limited, be wound up voluntarily, and that Henry Charles Gover, of No. 100, Victoria-street, in the city of Westminster, be, and he is hereby appointed, liquidator for the purpose of such winding up, and that the liquidator be, and he is hereby authorised to carry into effect upon the terms of a provisional agreement between the two companies dated June 5 (subject to any modification), a sale of the Company's undertaking to the Edison and Swan United Electric Company, Limited, for debenture stock of that company to be distributed among the members of this Company."

Manchester.—At Wednesday's meeting of the Town Council, Mr. Alderman Higginbottom called attention to the statements made at a recent meeting of the Manchester and Salford Trades Council to the effect that most of the work done under the direction of the Electric Lighting Sub-Committee had been performed by non-union labour, and at a lower rate of wages than that which was paid to union workmen. The statements had been carefully enquired into, and were found to be absolutely incorrect in every particular. They had nothing, Mr. Higginbottom said, to do with the question whether a contractor employed union labour or non-union labour; all they had to see to was that the standard rate of wages was paid. As a matter of fact, the wages paid were in excess of the standard rate. As to the running of the station, the fact was that instead of there being only two or three persons who received 8d. an hour there were 10. No one received so low a rate as 4d.; the average was 5½d., and in all cases the payment, because of the exceptional nature of the work, was in excess of the standard rate of wages in the district.

Consolidated Telephone Company.—The thirteenth annual general meeting of the Consolidated Telephone Construction and Maintenance Company, Limited, was held last week at Winchester House. Mr. C. L. W. FitzGerald (the chairman), in moving the adoption of the report and accounts, said that in accordance with the resolution passed last year by the shareholders the capital had been reduced. They had paid back to the preference shareholders £27,637 and to the ordinary shareholders 2s. a share, representing £22,485. The capital now stood at 224,850 ordinary shares of 10s each, fully paid. An independent valuation of the plant and machinery showed that instead of £5,300, at which it stood in the accounts, it was actually worth £7,000, so that they had on that nearly £2,000 in hand, under which circumstances the directors considered it unnecessary to write off anything on plant and machinery this year. During the past few months the business had decidedly improved, and although they had hoped to have done better, he thought the fact that they were able to pay the same dividend as last year must be regarded as satisfactory. The motion was carried, and a dividend of 2 per cent. declared, as recommended.

Larne.—At the monthly meeting of the Town Commissioners the clerk read a letter from Mr. Archer Turner, resident electrical engineer, with regard to the hours of lighting, as follows: "With reference to the clause in the new lighting agreement relating to the hour of lighting the lamps, I shall be obliged if you will inform the Board that I have written to and received replies from the electrical engineers of Whitehaven and Weybridge, and from the engineer of the Corporation gasworks, Belfast. The replies from Whitehaven and Weybridge state that they light the town lamps one hour after sunset and that the lamps are all lighted at the same time. The engineer of the Belfast gasworks has kindly sent me the table of time for lighting and extinguishing the lamps, which, on average, is about one hour after sunset for lighting. From the replies you will see that our proposal as to the time of lighting is a very reasonable one, and is more favourable than the plan adopted in the two towns above mentioned which have electric light. I understand the receiver and manager has written you stating the terms on which he would be agreeable to light the lamps from sunset." After some discussion, Mr. Fullerton gave notice of motion for next meeting that he would move that the proposal of the contractors to light from dusk be agreed to.

Gas v. Electricity.—Mr. Henry Coles, electrical engineer, Cardiff, writes to the *Western Mail* as follows: "I note in your issue of Friday last a statement to the effect that the electric current supplied at 6d. per Board of Trade unit is equal, light for light, to gas at 6s. per 1,000ft. On Saturday, in your leading article, you state that the quantity of gas (at 2s. 10d. per 1,000ft.) purchasable for 3·25d. will give an equal amount of light to one Board of Trade unit, which in the instance of Cardiff will cost 6d. Now, are not both these statements rather terrifying to intending consumers, apart from your assurances as to the great economy which works out in practice? The actual facts, as I experience them, are these: A 16-c.p. incandescent lamp can now be obtained which will consume one Board of Trade unit in 18 to 20 hours. A No 6 Bray's gas-burner in the same time (at 6ft. per hour) will consume 120 cubic feet of gas of varying quality and illuminating power at a cost, therefore (at 3s. per 1,000ft.), of slightly over 4½d., as against the electric unit of 6d. I, though, perhaps, a biassed person, can fully endorse what you say in regard to numerous shopkeepers finding their electric lighting bills rather less than their gas accounts for the quarters previous to the installation of the electric light, notwithstanding the efforts made by the gas interests to push forward numerous so-called 'rivals' and 'substitutes' of their own."

Lighting of Tiverton.—Mr. J. Siddalls, the borough surveyor of Tiverton, states in his sixth annual report for the year ended Lady Day, that in February, 1893, he presented a report on the electric lighting of the town by means of water power, and after consideration of the same the Council decided to let the subject remain in abeyance for a time, with a view, if possible, to some method being devised to commence the work on a smaller scale, involving a less capital outlay at starting, and the town clerk and himself were instructed to attend before the Board of Trade and ask for an extension of time. They had an interview with Sir Thomas Bloomfield, of the Electrical Department of the Board of Trade, on June 29, and after explaining the position of affairs, were informed that the Board would allow the provisional order to run for a further period of one year without any steps being taken by them to revoke the order, on the understanding that at the end of the year some proposal for carrying it into effect should be submitted to them. The committee, after some further enquiries, have recommended the Council to endeavour to ascertain the terms upon which Messrs. Heathcoat and Co. would be willing to sell

Digitized by Google

the gasworks to the Council, the committee being of opinion that, providing reasonable terms could be arranged, it would most probably be advantageous to work the two enterprises—the supply of gas and electricity—together from the same works. The Council have adopted the report and referred back the subject for full enquiry to be made on the whole matter, which is now being done.

A Question of Solicitor's Costs.—In the Queen's Bench Division on Monday Mr. Justice Cave and Mr. Justice Collins gave judgment in an application made on Friday in the matter of A. T. Ashwell, solicitor, for an order directing taxation of his bill of costs against the Elmore Wire Manufacturing Company, Limited. The application had been refused by the judge in chambers on the ground that the bill had been paid. The company, in now appealing, urged that there were gross overcharges on the face of the bill which constituted "special circumstances" such as would justify the Court in directing taxation. Mr. Justice Cave, in giving judgment, said that, looking at all the circumstances, the proper conclusion appeared to be that the payment of £500 was not a settlement of the bill for £428, the balance going on account of the other bill, but a payment generally on account. He was not satisfied that the items complained of in the bill would amount to "special circumstances," which would justify the Court in directing taxation if there had been a settlement. No doubt a good many of the allegations of undue charges had been fairly explained away in the affidavits, although there were one or two items which it was reasonable to suppose might be reduced by the taxing master. Further, there were indications in the bill itself that it had been hastily prepared, and admittedly one or two items had been wrongly inserted. Under those circumstances the Court thought the best plan would be to send the bill for taxation, the costs of the present application to abide the result of the taxation.

Lighting at Cardiff.—A Cardiff paper states: "The Corporation have now reached the experimental stage in the contest of electricity *v.* gas for public lighting and private consumers. For the former, of course, the town is committed to electricity up to a certain limit, with provision for extension and development later on. Private consumers will need to be convinced that electricity is more advantageous than gas. In the case of those requiring motive power for machinery this may not be difficult, and, probably, shopkeepers will prefer a cool, clean light, without offensive fumes and non-injurious to goods, such as electricity has proved. It is in the case of private residences the rub will come, and it is here people will need to be convinced that electricity is the more advantageous. There is no doubt, light for light and hour for hour, electricity at the price which the Cardiff Corporation propose to charge is dearer than gas. No doubt those who swear by gas are rejoicing at the fact, and hugging themselves in anticipation of the practical collapse of their rival. But the end is not yet. The advantage of electricity, apart from the question of the quality of the light, is in the readiness with which it lends itself to economy of consumption. Gas companies' monopolies are generally most grievous to be borne, and the prospect of relief will be hailed with a good deal of satisfaction by many people. The work of lighting Cardiff by electricity has been going on apace, and at the present time the bulk of the work has been finished. The pipes for carrying the wires, etc., have all been laid, most of the lamps are in position, and the machinery has arrived at the works and is about to be erected. It is almost certain now that the scheme will be carried out about the middle of July next."

Acton.—Mr. T. W. Baker, of Broad-street House, E.C., writes to a local paper as follows: "I notice that the Acton Local Board are advertising for tenders for the transfer of their electric lighting provisional order, and as a 10 years' ratepayer and resident in that district, and having some little knowledge on the matter, I could not well let the opportunity pass without pointing out what I consider will be a loss to the ratepayers if these powers are delegated. It has been always found that a public authority can borrow at a cheaper rate than private individuals, and for these purposes 3½ per cent has been the rate of interest on which loans have been made to other authorities; but another, and I think a far more important, reason exists—that is, the use of the ashbin refuse of the district for generating the steam required for an electricity generating station. Ealing and St. Pancras are just now placing such arrangements in active use, the ashbin refuse being used as merely an adjunct, whereas several other vestries are contemplating it as the main source of heat, coal being supplementary. As the question of dust destruction has been and is becoming a question that the Local Board has to take in hand very shortly, I suggest that it should be taken in hand at once, and by a composite scheme of utilisation, and not only destroyed for the mere destruction, but so as to form a considerable factor in giving the electric light to the locality, with a saving of about 10 per cent. in the cost of that light. There is also no doubt that larger electricity generating stations can be worked more economically than the smaller, and I should suggest that a unified scheme with some other neighbouring authority would be advantageous to both. Being the adviser to more than one local authority on these questions, I have ventured to place my protest against any bartering away of the ratepayers' privileges in this matter of the electric lighting of the district without the subject being maturely considered in all its relations to the welfare of the locality, both in regard to comfort and pocket."

The Exhibition at Dover.—The recent electrical exhibition at the Town Hall, and to which reference was made in our last issue, was a good demonstration of electric light for Dover. The original intention of the Dover Electric Supply Company was to invite the public to come and see the Town Hall lighted for the first time with electricity. Subsequently the idea further developed itself into an exhibition which would show that, in addition, electricity could boil, broil, warm rooms, heat the laundresses' iron, drive a tram, and thrown in were the novel attractions of the telephone and the phonograph. The public exhibition was fixed for Friday and Saturday evening of last week, but a large number of invitations for a private view in the afternoons of those days were sent out, and numerously responded to. The Mayor, Sir William Crundall, chairman of the Dover Electric Supply Company, Mr. Bagshawe, one of the local directors, and Mr. Worsfold Mowll, solicitor to the company, were present to receive the guests. The arrangements for the temporary supply of current were made by fixing in Messrs. Finnis's saw-mills dynamos, which were driven by a pair of horizontal engines. The arrangements were under the control of Mr. W. H. Tasker, the engineer of the Brush Company, who is superintending that company's operations in Dover. Nothing could have answered better, and two or three nights before the exhibition the new light was produced. Perhaps the most demonstrative exhibit was Mr. Holt's electromagnetic car, which on a raised pair of rails was running to and fro with untiring energy. On a stand over his railway Mr. Holt also exhibited an engine driven by electricity. Cooking and heating by electricity was illustrated by numerous stoves, kettles, ovens, frying pans, etc., placed on the platform by the General Electric Company. In another part of the room was a stand supplied from Mr. Webster's Alexander Works, at Folkestone, where electro-plating in gold and silver was going on. Mr. Crofts had on view the Deal dynamo, which he has made for the use of amateurs.

Wrexham.—The minutes of the Council meeting held on April 24, and presented at a meeting last week, contained the following with regard to the electric lighting order. Messrs. Lewis and Son, of Wrexham, wrote to the town clerk as follows: "Your letter of April 3 has been discussed and considered by our board of directors, and we are now authorised to state that with a view of securing this order to the town, although it will be a serious sacrifice to the company, they will accept £350 for their rights in the undertaking, providing this offer be accepted without delay; and, in case it should be declined, that the above price be considered as having been named confidentially and not published." The town clerk having pointed out the difficulty of preventing publication, Mr. Bernard Lewis stated that the condition should be waived. Mr. Murless moved, and Mr. Davies seconded, that the Corporation should accept the offer of the Wrexham and District Electric Lighting Company to sell, at the sum of £350, all rights of and in their undertaking, subject to the transfer of the provisional order, including the vesting by the company (with the sanction of the Board of Trade) and confirmation of all incidental and necessary powers in the Town Council, being carried out by the electric supply company, free of any cost or expense to the Corporation; the matter to be completed within 18 months from this date, but that it be expressly understood that if any insuperable difficulty should be found to prevent the carrying through of the arrangement now proposed, the Corporation reserve the privilege of withdrawing or cancelling this conditional offer without prejudice. This motion was carried. The town clerk read at a meeting of the Council last week a letter from Messrs. J. Lewis and Son, that the directors of the Wrexham and District Electric Supply Company, Limited, would be prepared to fall in with the proposals made by the Town Council, provided the Board of Trade could approve of the same, and would make the costs of transfer light, and suggested that a joint memorial should be signed and sent to the Board of Trade. Alderman Bevan agreed that the costs of the transfer should be made as light as possible, and he thought the method suggested was the proper way to raise the question. He thought the memorial was the right way to raise the question, and moved that the draft of the document, which would have to be sealed, should be submitted to the Council for approval. Mr. Hopley Pierce seconded, and the resolution was carried.

Electric Lighting in Londonderry.—At a meeting of the Town Council last week, the town clerk read Mr. Blake's final report on electric lighting. It stated: "I beg to submit my report upon the working and testing of the works contracted for by Messrs. Alexander Brown and Sons for the street-lighting of Londonderry by electricity. Since March 17 the boilers have been almost continually under steam, and have proved to be well up to the specification in every respect. They have been worked alternately, each boiler being of ample power for the lighting of the city with easy firing and ordinary Welsh steam coal. During the six-hours' test on May 8 and 9 the boilers evaporated 8·75lb. of water per pound of coal, which is a highly satisfactory result. The fuel economiser is entirely in accordance with the specification, and its working is satisfactory. The value of it is clearly demonstrated by the fact that the feed water, by being passed through it, is raised from a temperature of 55deg. F. to 180deg. F., showing a saving of 10·46 per cent. of fuel. The saving would be still greater if the boilers were working under a heavier load. The engines are satisfactory, and in accordance with the specification, which provided for three compound condensing inverted vertical engines, each capable of indicating 100 h.p., at a piston speed not exceeding 450ft. per minute, and with a steam pressure of 110lb. per square inch at the steam-chest, and a vacuum in the condenser of 24in. When officially tested for six hours on May 8 and 9 the average consumption of steam was 18·45lb. per indicated horse-power per hour, or 2·05lb. of coal per indicated horse-power per hour, showing a result better than that provided for in the specification of 25·5lb. of steam, or 2·83lb. of coal per indicated horse-power per hour, which is a saving of over 11 per cent. I consider these engines to be well

Digitized by Google

suited for their work; strong and well constructed throughout. I consider this complete duplication of the steam-pipes, with the present position of the engines, an improvement on the ring main; but before adopting it I went to London and consulted Dr. John Hopkinson on the matter, and got his approval of the same in writing. The valves and joints are in good order, and of a class which leaves nothing to be desired. I have no hesitation in saying that Messrs. A. Brown and Sons and Messrs. Siemens Bros. and Co., Limited, have completed all the works in their respective contracts, and also the extras ordered, to my entire satisfaction. I further beg to report that Mr. M. M'Clelland has completed all the works in his contract for erection of buildings, etc., and also the extras ordered, to my entire satisfaction." The town clerk also read the report of Mr. Alex. Craig, mechanical engineer, stating that the Corporation have got useful machinery, capable of performing the required services. Councillor Turner proposed that these reports be adopted, that the Corporation take over the works, and that a sub-committee be appointed to order the extinguishing of such lamps as are not required. Councillor Lane seconded. After some discussion concerning the testing of the plant, the reports were adopted.

PROVISIONAL PATENTS, 1894.

MAY 28.

10228. **Improvements in deodorising and purifying sewage or other waste liquors containing organic matters, in combination with generating and storing electricity, and in means or apparatus therefor.** W. H. Hill-Hartland, 728, Grimesthorpe-road, Sheffield.

10292. **A novel mode of illuminating watches, clocks, compasses, barometers, and similar instruments boxed up in metal cases by means of electricity.** John Manger and Edward Mojon, 26, Bartlett's-buildings, London.

10,293. **A portable electric lamp.** John Manger and Edward Mojon, 26, Bartlett's-buildings, London.

10331. **Improvements in conductors for electrically-propelled tramway and railway vehicles.** Fritz Bernhard Behr, 28, Southampton-buildings, Chancery-lane, London.

10332 **An improvement in regulating apparatus for electric arc lamps.** Sidney John Suter, 28, Southampton-buildings, Chancery-lane, London.

10353. **Improvements in pendant fittings for electric lamps.** John Morris, jun., 40, Chancery lane, London.

10364. **Improvements in electrical devices suitable as meters, motors, dynamometers, and the like.** Emmanuel Dragoumis, 323, High Holborn, London.

MAY 29.

10384. **Improved carbon for electric lighting and other electrical purposes.** George Sheridan Orson, 99, Rugby-avenue, Belfast.

10386. **Improvements in or applicable to clocks for operating electrical lamps.** Ferdinand Fritz, 70, Deansgate, Manchester. (Complete specification.)

10425. **Improvements in electrical transformers.** John Augustine Kingdon, 29, Marlborough-hill, St. John's Wood, London.

10426. **Improvements in dynamo-electric machines.** John Augustine Kingdon, 29, Marlborough-hill, St. John's Wood, London.

MAY 30.

10463. **Improvements in cells or boxes of electric batteries.** John Miles Moffat, 2, Heath-villas, Cargill-road, Earlsfield, London.

10497. **Improvements in electrical measuring and signalling instruments.** Herbert Watson Sullivan, 29, Ladbroke-square, Notting Hill, London.

10490. **Improvements in the method of and apparatus employed for heating steel wire by electric currents.** John Platt, George Hotel, Cleckheaton, Yorks.

10524. **A novel arrangement of screens and shades with means for affixing same to lamps, such as candle, oil, electric incandescent, or other, such screens or shades being adapted for holding and supporting flower sprays or other ornamental objects.** Joseph Henry Rosoman, trading as Smethurst and Co., 166, Fleet-street, London.

MAY 31.

10565. **Phase transformers for electric currents.** Silvanus Phillips Thompson, The Finsbury Technical College, Leonard-street, City-road, London.

10586. **Improvements in wall sockets for electric lighting.** Gustaf Charles Lundberg, 18, Regina-road, Tollington-park, London.

10590. **A combined switch and holder for an electric glow lamp.** The Edison and Swan United Electric Light Company, Limited, and Charles Faraday Proctor, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

10594. **Improvements in or in connection with magneto-electrical telephones.** Max Frank, 34, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JUNE 1.

10634. **Improvements on arc lamps.** James William Rogers, 7, Hargrave-park, Upper Holloway, London.

10658. **Improvements in electric chimes.** Frederick William Golby, 36, Chancery-lane, London. (Albert Neumann, Germany.) (Complete specification.)

10659. **Improved apparatus for the suspension of incandescent electric lamps.** Frederick William Golby, 36, Chancery-lane, London. (Albert Neumann, Germany.) (Complete specification.)

10660. **Improvements in or relating to incandescent electric lamps.** Frederick William Golby, 36, Chancery-lane, London. (Albert Neumann, Germany.) (Complete specification.)

10672. **An improved device for casting electric accumulator plates.** Carl Hampel 6, Lord-street, Liverpool.

10687. **An improved electric fire-alarm apparatus.** Louis Borel, 40, Chancery-lane, London.

10701. **Improvements in electrical connections for marine purposes.** Charlas Scott Snell, Culver-park, Saltash, Cornwall.

JUNE 2.

10745. **A continuous-magnetic motor.** Isaac Carruthers, 17, Lower Rock-gardens, Brighton.

SPECIFICATIONS PUBLISHED.

NOTES.

Bischoflak.—This town is to receive the electric light by August 1 next.

Madras.—The new post office and other public buildings are to be lighted by electricity.

Electric Lighting at Lyons.—The gas company are extending their electric lighting mains.

Antwerp Exhibition.—The machinery building was formally opened on Tuesday by King Leopold.

Telephony at Bordeaux.—Complaints are being made that the telephonic service is deplorable.

Society of Arts' Conversazione.—This will be held at the Imperial Institute on the evening of Friday, 22nd inst.

Long-Distance Telephony.—Telephonic communication is to be established between Munich, Leipsic, and Berlin.

Junior Engineering Society.—On Saturday, the 16th inst., at 4 p.m., the Wembley Park Tower works will be inspected.

Soleureville.—The Communal Council is in negotiation with Messrs. Siemens and Halske for the supply of electric current.

Electric Lighting at Rochechouart.—A local company is being formed to establish a central electric lighting station here.

New Electrical Workshop.—A new electrical workshop for students is to be established in Paris in connection with the Ecole Diderot.

Ship-Lighting.—The new torpedo-boat destroyer, the "Hornet," tested on Saturday, is equipped with a complete electric light installation.

Geneva.—A proposal is under consideration for the construction of an electric tramway between Champel and Petit-Saconnex *viâ* Geneva.

Rapid Transit in New York.—A Bill has now been passed which will facilitate rapid transit in New York by the aid of electric traction.

Saint-Claude.—M. Passot, an electrical engineer, has applied to the Municipal Council for authority to establish a central electric light station.

North of England Institute of Mining Engineers. A general meeting will be held in the Grand Hotel, Whitehaven, on Thursday next.

Telegraphy in Turkey.—The Turkish Government have ordered the publication of a manual of telegraphy in Turkish for its telegraphists and the public.

Niedersedlitz.—Messrs. Krummer and Co. have projected the construction of an electric tramway from Niedersedlitz *viâ* Kreischa and Lungwitz to Maxen.

German Emperor.—The German Emperor has just had constructed a carriage which is lighted by electricity, and electric lamps are also fixed to the harness.

Basle.—The Municipality have decided to construct an electric tramway between the Baden railway station and the Central railway station at a cost of £28,000.

The Alhambra.—The grand circle has been transformed into a very pretty promenade, and electric lighting assists in enhancing the effect of the decorations.

Meters in Austria.—Measures are being taken by the Austrian Minister of Commerce with a view to the introduction of a standard system of electricity meters.

Islington.—The annual report of the Islington Vestry contains a historical account of the steps taken by the Vestry up to the present in regard to electric lighting.

Traction in Hamburg.—It appears that since the local tramway company introduced electric traction on their lines the gross receipts have very considerably increased.

Schwanenstadt. — Messrs. Siemens and Halske, Messrs. Ganz and Co., and the Oerlikon Works are preparing estimates for an electric light station for this town.

Traction at Konigsberg.—The Union Electricity Company are negotiating with the Königsberg tramway company with a view to the introduction of electric traction.

Calcutta.—The governing body of the United Service Club have decided to light the club premises by electricity. The work will be carried out by Messrs. Octavius Steel and Co.

Railway Station Lighting in France. — The Northern Railway Company are going to light the whole of Creil Station, with the exception of the waiting-rooms, electrically.

Central London Railway.—The Bill, which grants an extension of time until 1900 within which to construct the Central London Railway, has now been sanctioned by both Houses.

Trautenau.—The Municipality have commissioned Messrs. Siemens and Halske, of Vienna, to establish a central station for the supply of 3,000 16-c.p. lamps on the three-wire system.

Crimmitschau.—A projection is on foot for the erection of a central electric light station here. Promises have been received for 56 arc lamps, 3,665 incandescent lamps, and 29 electromotors.

Exhibition at Cardiff.—A fine arts, industrial, and maritime exhibition is to be held in Cardiff next year. Mr. Councillor T. H. Riches is the chairman of the machinery and electricity section.

Worthing.—The expenses of the Town Council in connection with the Hermite tests have totalled £168. 16s. It will be remembered that £200 was the limit fixed by the vote of the Council.

Electric Tramway at Lomberg.—The greater portion of this line has been completed and opened for traffic. The work has been carried out by the Union Electricity Company, of Berlin.

The Great (?) Unknown.—It appears that a man has been stealing electricity in Berlin. If it had been sheet lightning it would not have mattered, but it seems that this is unknown in that city.

The Pollak Accumulator.—A company has been formed under the title of the Akkumulatoren Werke System Pollak, at Frankfort-on-the-Maine, to acquire the business carried on hitherto by Messrs. C. Pollak and Co.

Electric Tramway in Switzerland.—The projectors of a tramway between Hirslanden and Grüningen, in the canton of Zurich, have decided to adopt electric traction, with a generating station on the Forch.

Wiring of Ships.—We note that the committee of Lloyd's Registry are contemplating substituting definite rules for the wiring of ships in the place of their former suggestions, and that they are now drafting such rules.

Iglo.—A local company have concluded a contract with Messrs. Siemens and Halske, in Budapest, for the erection and equipment of a station which is to supply 2,500 incandescent lamps. The work has already been commenced.

Digitized by Google

Binningen.—The introduction of the electric light into this Swiss town seems to be assured. There have already been secured a sufficient number of subscribers, and others are expected. The price per lamp is to be 2d. per hour.

Electric Light at Holzkirchen.—The local authorities have decided to erect a central electricity station, utilising the water power of the Mang Fall. The electrical part of the installation will be carried out by Herr Oskar von Miller.

Institution of Engineers and Shipbuilders.—The annual excursion of the members of the North-East Coast Institution of Engineers and Shipbuilders will take place on July 19, when the works of the Consett Iron Company will be visited.

Lightning.—It appears that the members of the Italian fire brigade are very prompt in responding to alarms of fire. According to an illustration in *L'Elettricità*, the firemen arrive at houses struck by lightning before the lightning flashes disappear from view.

Tenders for Electric Tramway.—The Communal Administration of Jekaterinsdar (Government of Kouban, Russia) will receive up to July 25 offers for the establishment of tramways for either electric or mechanical traction in the town of Jekaterinsdar.

Electric Lifts at Berne.—It is proposed to construct electric lifts, so as to facilitate access to the higher parts of the town, which are about 100ft. above the lower parts. The lifts are to have a capacity of 1,900 persons per day. An 8-h.p. electromotor will be employed.

Technical Education in London. — We have received a copy of the annual report for 1893-94 of the Technical Education Board of the London County Council. The report may be obtained from Mr. E. Stanford, 26 and 27, Cockspur-street, Charing Cross, S.W.

Exhibition at Geneva.—A National Swiss Exhibition is to be held at Geneva in 1896. The thirty-eighth section—industrial electricity—will have M. d'Everstag as president, Prof. Denzler, of Zürich, and Prof. Palaz, of Lausanne, as vice-presidents, and M. Cuenod as secretary.

Salzburg.—The capital of the Salzburg Electricity Works, which had already been raised from 500,000 florins to 600,000 florins, has now been increased to 1,000,000 florins. The central station now supplies current to 6,400 lamps, and further 1,000 are to be connected.

Long-Distance Transmission of Power.—The Italian Society for the Protection of National Industry are bestirring themselves with a view to the introduction by the Government of regulations for the promotion of the electrical transmission of power over long distances.

Electric Vehicles.—More attention is being paid in the United States to the question of self-contained electric vehicles. Mr. G. R. Cummings, of Chicago, is demonstrating an electric carriage which is claimed to run at 10 miles an hour, with an expenditure of from 1¼ e.h.p. to 2 e.h.p.

Boiler Incrustation.—The use of petroleum as a means of preventing boiler scale in boilers has been tried for some time in Germany. Mr. Vogt, in the annual report of the Bergisch (Rhenish-Westphalia) Boiler Society, writes deprecating its employment on account of the damage done to the boiler plates.

Central Station at Frankfort-on-the-Maine.—The buildings are well advanced, and ready for the iron roof. The foundations for the boilers and engines are in process of building. The new central post office will only be partly lighted by electricity, to the extent of about 700 incandescent lamps and a number of arc lamps.

The Pacific Cable Question.—Mr. Mercer, of the Colonial Office, has been appointed as a delegate to act in conjunction with Lord Jersey at the Ottawa Commercial Conference, where the question of the proposed all-British-Pacific cable is to be discussed next week. Lord Jersey and Mr. Mercer left yesterday for Ottawa.

Electric Lighting at Vienna.—It is proposed to adopt the electric light at the Vienna University, for the Mineralogical Institute, the Mineralogical Museum, the Geological Institute, the Geographical Institute, and the Chemical Institute. Herr Ernest Heinrichs, the building inspector of the university, has drawn up the plans.

Traction in Switzerland.—A central station is to be erected at Wynau by Messrs. Siemens and Halske, and a scheme is being discussed for the laying down of an electric tramway between Langenthal and Huttwyl. At Oensingen a proposal is under consideration for the construction of an electric tramway to connect that town with Balsthal.

Indiarubber in Ecuador.—The British Consul at Guayaquil states that the production of indiarubber is slowly declining, owing to the reckless manner in which whole groves of these valuable trees are being cut down. No provision for future needs is being made by the planting of young saplings, as in other rubber-producing countries.

Lighting at Caen.—The central electric light station at Caen was to have been set in operation last Saturday. This station has been carried out by the Compagnie Nationale d'Electricité (Ferranti) on behalf of the Société Régionale d'Electricité. The journal *L'Electricien* promises to give a description of the station in its issue of June 16.

Sparrows and the Electric Light.—The inspector of electric lighting reported this week to the Bath Surveying Committee that a lamp in Hall-street had failed temporarily through a sparrow's nest having been built in a pipe through which the wires were taken. The nest had become sodden with wet, and saturated the covering of the wires.

Electricity in Mining.—In the course of his presidential address before the Federated Institution of Mining Engineers last week, Mr. Arthur Sopwith said that electrical transmission of power was a distinctly recent feature in mining, but it was not too much to say that it had been brought up in line with its old-fashioned competitor—compressed air.

Traction at Newcastle.—A meeting of the Town Improvement Committee was held on Friday for the purpose of considering the recommendation of the Tramways Committee embodied in the report of the city engineer, which was given in our last issue. It was agreed to recommend the adoption of the cable system for running the trams.

Engineering, Shipbuilding, and Metal Trades.—A conference will be held at the County Hall, Spring-gardens, S.W., on Wednesday next, to discuss the subject of technical education in its relation to the engineering, shipbuilding, and metal trades. The chair will be taken at 8 p.m. by Mr. Sydney Webb, chairman of the Technical Education Board of the London County Council.

Lighting at Interlaken.—The local lighting company are just completing a small central station. There are laid down two turbines, each of 175 h.p., and one of 25 h.p.; the former will actuate two alternating-current machines, and the latter the dynamo for the supply of the exciting current. The principal railway station and the districts of Matten and Unterseen will be electrically lighted.

Gas v. Electricity.—In connection with the electric lighting of Newport, Monmouthshire, the *South Wales Daily*

Digitized by Google

News says that "The Newport Gas Company, as a counter-blast, are sedulously pushing the Welsbach patent gas-burner. Gas as an economical cooking agent evidently has a great future before it, but as a light producer under existing conditions it cannot be said to be long-lived."

Petroleum-Engine Competition.—A competitive test of petroleum-engines has been opened and closed by the Société d'Agriculture of Meaux. We note that a medal has been awarded to Messrs. Griffin and Co., of Bath, for their engine, and that honourable mention is made of the engine made by Messrs. Hornsby and Sons, of Grantham, both being made through the Paris agents of the two firms.

Royal Meteorological Society.—An ordinary meeting of this society will be held at 25, Great George-street, Westminster, on Wednesday next. Papers on the following will be read: "Fogs Reported with Strong Winds during the 15 Years 1876-90 in the British Isles," by Mr. Robert H. Scott, M.A., F.R.S.; and on "Some Characteristic Features of Gales and Strong Winds," by Mr. Richard H. Curtis, F.R.Met.Soc.

Alais.—The question of introducing the electric light into this town has been under consideration for some time. The local authorities have laid down certain stipulations for the concession, and these have been accepted by Messrs. Louche, Bonnefoy, and Froment. The gas company has been notified as to this, and will now have to decide definitely whether they will exercise their prior right to provide the electric light.

The "E. E." Up to Date.—The brief summary given by our correspondent in another column of the proceedings at the meetings last week of the two principal electrical societies in Germany is very interesting. We always endeavour to give our readers bright, practical, readable, and up-to-date information, and we tender them our sincere thanks for the many kind letters of appreciation of our humble efforts in this direction.

Strassburg.—In our last issue we referred to the position of the project for the electric lighting of this city. The firms competing are the Bremen Union, the Frankfort Electrical Works, Messrs. Siemens and Halske, the Helios Company of Cologne, and the Berlin Electricity Company. It is proposed to erect a turbine station on the Rhine. It is hoped that the works will be completed by the time of the exhibition next year.

The Paris Exhibition.—The first meeting of the 1900 Exhibition Commission took place on Friday under the presidency of the Minister of Commerce, M. Lourties. The fourth group is "The *Matériel* and General Processes of Mechanics," including steam-engines, motors, divers apparatus of general mechanics, and implements. The fifth group deals with electricity, including the production and mechanical application of electricity, electro-chemistry, electric lighting, telegraph, and telephone.

Vevey-Montreux.—The report of the directors of the Société Electrique de Vevey-Montreux for 1893 shows that the number of passengers carried on the tramway was 1,309,240, or an average of 3,586 per day, the total receipts being 225,322f., or, say, £9,013. On December 31 last the company supplied current to 9,032 incandescent lamps and 35 arc lamps. The receipts amounted to 187,835f., or, say, £7,513. The total net profit amounts to 146,406f., or, say, £5,856. A dividend of 5 per cent. has been declared.

High-Speed Steam-Turbine.—Our Italian contemporary, *L'Elettricità*, in its issue of June 10, states that the Oerlikon Engineering Works have constructed a Laval steam-turbine coupled to a 5-h.p. dynamo. The same journal says that the speed of the turbine reaches the remarkably high rate of 30,000 revolutions a minute, and that of the dynamo 3,000 revolutions. The efficiency of the dynamo during the first tests is given as 85 per cent., and the consumption of steam per horse-power hour at 15·7 kilogrammes (34½lb.).

Znaim.—The three-wire system of distribution is to be adopted in this Moravian town, where, as we have already stated, a central electricity station is to be erected. A site has been chosen in the north-eastern part of the town. There will be space for four Babcock and Wilcox boilers, and for four 65-kilowatt Siemens and Halske steam dynamos; but to begin with, only two boilers and two engines and dynamos will be installed. Two batteries, each of 68 Tudor cells, will be employed. Overhead conductors are to be used. The installation is to be completed by November next.

Silvertown Dynamos.—A new list of the various types of Silvertown dynamos made by the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, has reached us. These generators are all of the continuous-current type, and those illustrated in the list are the company's standard types for incandescent lighting. They are arranged for belt driving, but slow-speed dynamos for direct coupling, high-pressure dynamos for the transmission of power, and special machines for arc lighting, electro-deposition, smelting, etc., are also constructed by the company. The Silvertown dynamos are so well known as scarcely to need any recommendation; they are made of powers ranging from 3 b.h.p. to 76 b.h.p.

Electrical Communication with Lightships.—In the House of Commons last week, Mr. Bryce said, in an answer to Mr. FitzGerald, that in the last financial year £10,000 was placed at the disposal of the Board of Trade for the purpose of effecting electrical communication with light-vessels, etc. That money was expended in connecting the Kentish Knock and Goodwin (N. Sand Head) light-vessels and the Gunfleet pile lighthouse with the shore. In the present financial year £11,000 had been similarly placed at the disposal of the Board of Trade, and it was intended to expend this amount in connecting the Haisborough and the Shipwash light-vessels with the shore and in laying a cable to the Tuskar Rock lighthouse. The other works recommended by the Royal Commission must, he was afraid, wait until the Treasury could place more money at his disposal

Electrical Engineering in Siam.—In the course of a paper read last week before the Society of Arts, Mr. C. Stuart Leckie stated that the most popular local company in Bangkok is the tramway company, the management of which has been in Danish hands from the commencement. When the success of the concern was proved, the directors replaced the pony cars by heavier electric cars. An American firm got the orders for this installation, and the work seems to have been well done, judging from the regular working for the first year. The directors are well satisfied that they have obtained greater efficiency and greater economy by introducing electric power. Cheap fuel for driving the generating plant is obtained from the sawdust from the neighbouring teak mills. Another company in Bangkok is the electric light company, with a splendid lot of machinery costing £50,000. The lighting has been delayed for a few years by financial difficulties, and matters are at a standstill.

Demonstration of Electric Cooking.—A demonstration of the use of electricity for cooking and heating purposes will be given to-day (Friday) by the City of London Electric Lighting Company at the Cannon-street Hotel, on the occasion of a dinner given by the directors of the company. The Lord Mayor and sheriffs will be

Digitized by Google

present at the dinner, which will be cooked by electricity. This step on the part of the City of London Company has doubtless been taken with a view to increasing the day load. There is a large field for the introduction of electric heating and cooking in the numerous City restaurants and cafés, whilst a fair scope, apart, of course, from lighting, is afforded the company in the direction of inducing the large business firms to adopt the electric heaters specially for use during the winter months. The directors of the City of London Company are to be congratulated upon having started this movement in the City, and we trust that their efforts will meet with success.

New Electric Light Regulations.—The following misleading paragraph is being published in numerous provincial papers: "Mr. Francis Hopwood, assistant secretary to the Board of Trade, has issued a circular letter notifying that the electric light regulations, dated July 6, 1891, are revoked, and promulgating new regulations and conditions for the safety of the public, and for ensuring a proper and sufficient supply of energy. In regard to the question of safety, it is provided that only a low-pressure supply shall be delivered to consumers, except in cases specially approved of by the Board of Trade. Various precautions are enforced as to maximum current and local heat, lightning protectors, and the enclosure of high-pressure conductors, continuous insulation, and the detection of leakage. Penalties amounting to £10 a day are specified for contravention of the new rules." We are informed by the Board of Trade that they have not issued any revised regulations for general adoption. The Board have recently approved the system of supply used by the London Electric Supply Corporation, which is slightly different from that formerly approved by the Board, but the regulations issued with the new approval were in no way altered.

The Lyons-Oullins Electric Tramway.—The electric tramway from Lyons to Oullins is the fifth in France where the overhead trolley system has been adopted, and the second in Lyons. The first runs between Lyon-Saint-Juste and Sainte-Foy. The new line, which forms part of the system of the Lyons Tramway and Omnibus Company, is about three and a half miles in length, and the maximum gradient is 3·5 per cent. The line is double for nearly the whole of the route and the curves are easy, but there is a long gradient, which proved very trying to the horses, and up which the cars travelled very slowly. Posts are placed opposite each other on either side of the road, bearing transverse wires, which support the conductors. The central station is near the Oullins terminus, and it is intended to extend the line to Saint-Genis-Laval. The building is in two sections—one containing the boilers and accessories, and the other the steam-engines and dynamos and the car depôt. The boilers employed are of the semi-tubular type, and made by M. Bonnet-Spazin, of Lyons. There are two steam-engines of the Duverger type, made by M. Piguet, of Lyons. They are nominally of 150 h.p., but can give 200 h.p. in case of need. The engines run at 100 revolutions per minute. The electrical plant has been furnished by the General Electric Company, of New York. There are two four-pole dynamos, each of a capacity of 100,000 watts. The rolling-stock comprises 10 cars, capable of each accommodating 40 passengers.

Optical Phase Indicator and Synchroniser.—Before the recent eleventh annual assembly of the American Institute of Electrical Engineers, a paper by Prof. G. S. Moler and Dr. F. Bedell, on "An Optical Phase Indicator and Synchroniser," was read. The apparatus described consists of a device for measuring the angular difference in the position of two shafts running at the same speed. When applied to a synchronous motor, this apparatus shows by direct reading the angle of lag of the armature of the motor behind that of the generator. The authors pointed out, however, that the instrument has a wide application in other lines of work—for instance, the measurement of small speed differences in power transmissions between two shafts, and in work of all kinds where synchronous operation is needed. The motor and dynamo are placed in line with ends abutting in the most simple form of apparatus described. A disc is placed on the end of each shaft. Each disc has a system of slits, and when the slits of one disc cross over those of the other a hole is formed by which light can pass through the two discs. When the discs are revolving synchronously, and a light is placed on one side of the discs, these holes appear as a ring of light. The slits in the discs are so constructed that this ring moves in or out if one disc is revolving more rapidly than the other. The distance of the ring from the centre is proportional to the angle of difference in the positions of the two discs. The apparatus is so arranged that this phase difference may be read directly.

Sterage Battery Phenomena.—In a paper read recently by Mr. W. W. Griscom before the late meeting of the American Institute of Electrical Engineers, the author discussed the question of "Some Storage Battery Phenomena," describing many experimental investigations of storage battery phenomena little understood at the present time. The diverse chemical products formed at different stages of charge and discharge were shown to largely account for the erratic form of the curves of E.M.F., and at the same time it was made manifest that the positive plate at times determines the characteristic curves of potential, whilst at other certain stages the negative plate asserts itself. The curious facts were mentioned that variations of capacities and even of E.M.F. exist in plates identical in history and position, and that one positive may discharge into its neighbour. It was illustrated that the rates of discharge in a cell of the different plates constantly varies in relation to each other. An actual decrease of temperature in a cell discharging was noted and explained as due to the simultaneous lowering of the specific gravity of the electrolyte, and it was indicated that, contrary to usual belief, a positive plate has more capacity than a negative one. Several phenomena for which explanations are wanting were referred to, including the changes shown in internal resistance, the simultaneous increase of internal resistance and potential, the tendency of a charged positive to buckle away from the light, and the sudden spontaneous discharge of a fully-charged positive. The commercial points of the storage battery question were considered, and the lack of success in the United States was attributed to no allowance of a margin of safety in the weight and working of a battery, the observance of which factors has led to success in Europe.

Corrosion of Gas and Water Pipes.—It seems that the Americans are determined to settle the question as to the corrosion of gas and water pipes by electrolysis. The following communication was recently sent by Mr. A. J. O'Reilly, supervisor of the city lighting of St. Louis, to the committee on public buildings and city lighting of the Board of Public Improvements, in reference to a method of ascertaining the results of the electrolysis of water-pipes: "It being desirable to make records of the electrolysis at various places along the water-pipe system of the city that comparison may be made of the relative extent to which the electrolysis is going on during a

Digitized by Google

definite time in various parts of the city, and, as this cannot be done with any degree of accuracy with the instruments available for the purpose, without a great increase in the number of observers, the following method has been determined upon by the Water Commissioners and myself. A connection will be made with the water-pipe at convenient stop-valve and fire-plug boxes with a small copper plate of known weight, and placed in the moist earth close to the water-pipe, and allowed to remain there for a definite time, its percentage of gain or loss in weight will be a measure of the current passing to or from the pipe through the plate and into the earth at that place. As a check, a similar test-piece of copper, not connected to the pipe, will be buried close to the other in such a way that it will be subject to the same conditions from action of soil and moisture on the copper which may take place independent of the electric current from the water-pipe. The proper corrections are to be applied on account of the action that may be set up between the iron and the copper independent of the earth return currents under consideration. I am led to believe that, by continuing experiments of this kind and keeping proper record thereof, the affected territory can be definitely circumscribed. The determination of the direction of the street railway return currents must be by voltmeter and ampere-meter methods."

The Influence of Moisture on Chemical Action. Since the publication of a note in the *Proceedings* of the Chemical Society on May 4, 1893, Mr. H. Brereton Baker, M.A., has made further investigations of the actions there mentioned. He finds that sulphur trioxide does not combine with highly purified lime; but a trace of moisture brings about vivid incandescence. Dry copper oxide is also without action on sulphur trioxide. Purified and dried lime does not decompose dried ammonium chloride, which may be sublimed from the mixture without evolving any ammonia. Purified and dried nitric oxide gives no brown fumes with dried oxygen, but a trace of moist air causes them to appear at once. A mixture of purified and dried hydrogen and chlorine can be exposed to daylight for four days without more than three-fourths of the gases combining. Ammonium chloride, heated in a vacuum in a soft glass tube, leaves a residue of ammonia gas; but when dried and heated in a hard glass tube, no gaseous residue is obtained. This led to the investigation of the vapour density of dry ammonium chloride, which was shown to be normal, 28·7 being the mean result of six experiments. With regard to the theory of the subject, the author believes that an electro-chemical hypothesis is applicable. Separation of dried ammonia and hydrogen chloride gases takes place when plates with opposite electrical charges are introduced into the mixture though the action cannot be electrolytic, since discharge is under the circumstances impossible. Similar separation was noticed with air and with a mixture of dried hydrogen and oxygen. Electric discharge, when not of high tension, will not pass in dried gases; but the high-tension discharge does pass, and renders it possible for the low-tension discharge to pass afterwards. With regard to the influence of moisture, it appears that what holds for chemical combination holds also for electrical discharge, and that there is great significance in the apparent similarity in the two cases.

German Fire Insurance Rules.—The regulations issued by the German fire insurance offices for the efficient carrying out of electric light installations in buildings insured by them were, up to the beginning of last year, of a somewhat antiquated character. This fact, according to Dr. O. Gusinde in the *Elektrotechnische Zeitschrift* of May 31, had long been recognised in interested circles, and an alteration was considered necessary. The Society of German Fire Insurance Companies in 1892 took the matter up more seriously, and invited Dr. Oscar May, Dr. C. L. Weber, and Dr. M. Krieg to form themselves into a commission to investigate the subject, and to formulate new regulations for controlling the erection of electric light and power installations. The scheme drawn up by the commission was laid before a meeting of the Society of Fire Insurance Companies in October, 1892, and was adopted, with certain modifications. Dr. May mentioned in the *Erläuterungen* that the work of the commission was based upon the proposals he made at the Electrical Congress in Frankfort in 1891, together with certain alterations. Opinions on the scheme were previously invited from five of the most important electrical firms, who, whilst not objecting to the projected regulations, made certain proposals. The text of the regulations was given on page 307 (1893) of the *Elektrotechnische Zeitschrift*. Several communications published in the latter journal have shown that the regulations have not received the unreserved acceptance of the electrical trades, whilst it has been publicly stated that they would not be generally recognised. It is for the purpose of inviting a general discussion of the regulations that Dr. Gusinde deals with the subject in our German contemporary. After criticising the text of the regulations, the author concludes that he has demonstrated that they cannot be generally accepted. A solution of the problem is necessary, and this, combined with the fact that large electricity works institute regulations of their own, induces the author to hope that the matter will be brought to a satisfactory conclusion.

The Battle of the Cuirasses.—There are now plenty of so-called bullet-proof cuirasses before the public, and the question has arisen as to whether the one or the other contains a metal plate other than steel or iron. With a view to testing this in regard to the Dowe cuirass, the *Pall Mall Gazette* has made an offer in the following terms: "We have devised and erected, in concert with Prof. Silvanus Thompson, F.R.S., the principal of the Finsbury Technical College, an electrical apparatus for proving whether or not the cuirass contains a metal plate, without in any way revealing the actual substance used. The apparatus consists of an induction balance arranged in the following manner: A large circular coil of fine wire is attached to the two poles of an alternating-current dynamo. On either side of this is suspended a smaller coil wound on a bobbin, and connected right and left handedly in series with a telephone receiver. The position of the coils is so adjusted that the currents induced by the central or exciting coil exactly balance each other, when no vibration can be detected in the telephone. If, however, a plate of any metallic substance, whether solid or built up, or constructed of gauze, be inserted between the central coil and either of the side coils, the balance is upset, and a clear ringing note is heard in the telephone. The action is so exact that no mistake can possibly be made, and sensitive enough to enable it to be at once detected whether the disturbance were caused by a large substantial plate or merely by fragments of bullets and steel fragments left inside the cuirass. If Herr Dowe and Captain Martin care to put their cuirass to this perfectly unexceptionable test, the apparatus is at their disposal, and we shall be pleased to invite Mr. Maxim to witness either his own triumph or his own discomfiture, and to collect a competent jury of scientific men and military experts, to be nominated by all parties concerned, in order to see the test fairly performed." The apparatus devised for this test was exhibited at the Royal Society soirée on the 13th inst. It appears that Herr Dowe and Captain Martin have declined to allow the suggested test to take place.

TWO IMPORTANT MEETINGS OF GERMAN ELECTRICAL ENGINEERS AT LEIPSIC.

(SPECIAL SUMMARY FROM OUR CORRESPONDENT.)

The city of Leipsic presented a festive appearance nearly the whole of last week—from the 5th to the 9th June. One of the reasons for this was to be found in the electrical exhibition in the Crystal Palace, which was opened on Friday, and which will be closed on the 17th inst. As to the exhibition, very little can be written. I may say, however, that it resembles most exhibitions of this kind; it represents pretty fairly the multifarious applications of electricity, and has much of a popular nature about it. Another reason was the fact that great expectations were on foot in anticipation of the visit of the members of two of the most important German electrotechnical societies, who had chosen Leipsic as their place of meeting, one slightly in advance of the other.

Representatives of Electricity Works.

The assembly of the first society—that of the members of the Free Union of Representatives of German Electricity Works (Freie Vereinigung der Vertreter von Deutschen Electricitätswerken)—took place on the 5th, 6th, and 7th. Thirty works were represented, including those of Copenhagen, Christiania, and Stockholm. Dr. Gusinde, of Hanover, presided over the assembly.

The proceedings of the gathering referred more particularly to the working and management of electricity works. Among other matters discussed were the precautions to be observed in the wiring of buildings, the prices charged for current supplied for lighting purposes and that furnished for motive power, the experience gained in working on the three-wire system with an insulated central conductor and with a bare middle wire, and the standardising of electricity and measuring instruments. Finally, the title of the union was changed to that of the Union of Representatives of Electricity Works (Vereinigung der Vertreter von Elektricitätswerken), the proceedings terminating with the election of Mr. F. Jordan, of Bremen, as president for the ensuing year.

Union of German Electrical Engineers.

The meeting of the second society—that of the Union of Electrical Engineers of Germany (Verband der Electrotechniker Deutschlands)—commenced on Friday. It was the second annual meeting; the first gathering in Cologne last year having shown the importance of this semi-commercial semi-technical organisation. The members assembled on the evening of the 7th, in the hall of the Pologne Hotel, where they were welcomed by Herr Lindner on behalf of the local electrical engineers, the address being suitably responded to by Herr Ross, of Vienna.

The opening ceremony of the proceedings took place in the Crystal Palace on the following (Friday) morning, when, in the unavoidable absence of Dr. Slaby (the president), who had suddenly been called away to Berlin, Herr Stübben, of Cologne, occupied the chair. There were about two hundred members present. Herr Georgi (mayor of Leipsic) extended a greeting to the visitors for the Town Council, and Prof. Wislicenus in the name of the university. Then Dr. Wiedemann opened the electrical exhibition in the Crystal Palace. A hasty inspection of the exhibits was made, and, after luncheon, the members of the union settled down—partly to the reading of papers and partly to a detailed examination of the exhibition.

Electro-chemistry of the Future.

Dr. Ostwald, of Leipsic, presented the first paper at the afternoon meeting on Friday, dealing with "The Scientific Electro-chemistry of the Present and the Technical of the Future." The author laid stress on the fact that scientific electro-chemistry as developed in recent years would largely assist technical work in new directions. After dealing with the question of electrolytes, the speaker stated that an improvement in thermo-dynamic machines was only possible in one way—namely, by working with higher starting temperatures. How that was to be accomplished must be left to technical men, but it might be remarked that a solution appeared to lie in the direction of gas motors. If it was possible to transform in some manner or other the chemical energy of fuel—in which the question of heat was left out of consideration—into mechanical work, they would not be bound to inconveniently high temperatures, and would be able to utilise the whole amount without being compelled to accept those inconveniences in the question of purchase. The solution of this great technical question—the provision of cheap energy—must be found in electro-chemistry, in the sense of some form of galvanic battery which at present could not be imagined.

Single Wire for Several Telephone Subscribers.

Herr F. Ross, of Vienna, then described the "Nissl telephone exchange system," to which you referred a few weeks ago. The object of the system is to reduce the installation cost and working expenses, and the author stated that the method allowed of several subscribers to communicate automatically over a single wire with the telephone exchange without interfering with each other. The principle of the method, as mentioned in a previous issue of your journal, is stated to be as follows: At a certain point to which a single wire has been carried is arranged clockwork mechanism which causes a shaft to revolve. The speed of this shaft is governed by the number of subscribers' instruments to be served. For instance, in the case of four instruments the shaft would make a complete revolution in one minute. On the circumference of the shaft are arranged contact-pieces upon which feathers slide in such a manner that individual subscribers are brought successively into communication with the exchange for a short period; when the shaft is at rest the connection lasts. Each subscriber is enabled to arrest the rotation of the shaft at any moment when he is in communication with the exchange. Similarly, the exchange can stop the revolving of the shaft. The bringing to rest of the shaft is effected by means of a current passing through an electromagnet which actuates an armature, causing a catch to be inserted in the cogs of a spur wheel. Arrangements are provided for indicating both to the exchange and to subscribers which contact is sliding under the feather.

Herr C. P. Feldmann followed with a paper on "Lead Safety Fuses." The first part treated of the calculation of fuses from various points of view; the second dealt with those factors which influence the current strength necessary to melt the fuses; and the third with the faults of fuses, coupled with the suggestion that the union should introduce a standard method of description of fuses.

Rotary-Current Plant and Rectifiers.

Herr W. Lahmeyer, of Frankfort-on-the-Maine, presented a paper on "The Arrangement of Rotary-Current Installations and Rectifiers." The author remarked that the arrangement allowed, on the one hand, of the maintenance of the pressure of the lighting current when a number of electromotors was used, and, on the other hand, an increase in the output of the primary machines. The principle of the method lies in the transmission from the secondary machines to the generators of a variable amount of magnetising current, according to requirements. The system, which allows of motors being practically employed, has been introduced by the Lahmeyer works at Bockenheim, and in the case of the transmission of 300 h.p. from Bozingen to Biel, in Switzerland. At present, two rectifiers of 600 h.p. are in course of construction at the Frankfort works.

Mr. Gisbert Kapp then gave a historical account of the development of electrical engineering in England, and mentioned the reasons that had led to the adoption of the systems of electric lighting employed. In conclusion, he referred to the existing and projected electric railways.

Dr. Carl Feussner, of Charlottenburg, read a communication treating of the Imperial Technical Institute (Reichsanstalt).

Pressure and Current Curves.

Dr. G. Rössler, of Charlottenburg, in a paper dealing with "The Pressure and Current Curves of Various Types

Digitized by Google

of Alternators and their Influence upon the Lighting Power of Alternating-Current Lamps," discussed some investigations which he had made, in conjunction with Dr. Wedding, in the electrotechnical laboratory of the Technical High School, in Berlin. The enquiries and tests made were undertaken in consequence of the difficulties experienced with arc lamps in the sense that no matter from which maker they were obtained, when taken to their destination, the lamps either did not burn properly or they would not work at all. In conjunction with the investigations, the author entered into the question as to the illuminating power of alternating-current arc lamps. A comparison between the lighting efficiency of direct-current arc lamps and alternating arc lamps showed the former to be more favourable.

General Business Matters.

Dr. Slaby, having returned from Berlin, presided at the commencement of the proceedings on Saturday, when the general business of the union was dealt with.

Herr Sluzewski, in presenting the second annual report of the union, stated that the number of members was about 800, being about the same as in the previous year.

Among other business transacted was the alteration of the name of the union to that of "The Verband Deutscher Elektrotechniker" (Union of German Electrical Engineers), with offices in Berlin. The union expect to establish a closer connection between German electrical engineers, and to obtain a permanent representation and advancement of German electrical engineering by (1) an annual meeting of the members in some German town, where an interchange of opinions on important questions by means of papers and discussions will be effected; (2) by bringing the members into personal contact; (3) by the efforts of the organ of the union; (4) by publication of a union journal and other publications; and (5) by other means permitted by the available funds of the union.

Mr. Kapp and the "Elektrotechnische Zeitschrift."

The President then reported on the agreement entered into between the Verband Deutscher Elektrotechniker and Mr. Gisbert Kapp, as general secretary to the union, and according to which an annual remuneration of 20,000 marks (£1,000) is guaranteed to Mr. Kapp. The meeting, with a large majority, approved the conclusion of the agreement, and the president welcomed Mr. Kapp as general secretary.

Mr. G. Kapp thanked the members of the union for their confidence in him, and assured them that he would earnestly endeavour to promote the welfare of the union.

The next item on the agenda was the approval of an agreement with the publishing firm of Julius Springer, of Berlin, and R. Oldenbourg, of Munich, according to which the *Elektrotechnische Zeitschrift* (the organ of the Electrotechnical Society of Berlin) now becomes the official journal of the union. This agreement was also adopted.

Prof. Budde, of Hanover, then presented a report dealing with exhibition questions, with special reference to the supply of light and power at the Berlin exhibition, by the intermediary of a syndicate of the union. A similar course is to be adopted in the case of the exhibition to be held at Carlsruhe.

Dr. T. Bruger, of Bockenheim, in a paper on "Some Direct-Reading Measuring Instruments," exhibited and described various forms of instruments.

Herr F. Teichmüller, of Mülheim-on-the-Rhine, read a paper on "The Conductivity of Copper." He stated that the specific conductivity of copper was expressed in so many ways as to lead to confusion. It was desirable therefore that a standard method should be introduced. The basis of a system must be the absolute measuring method, and he concluded with the expressed wish that a commission should be nominated to discuss the question.

Three-Wire System with a Single Dynamo.

Herr von Dolivo-Dobrowolsky, of Berlin, then presented a paper on "Direct-Current Machines on the Three-Wire System." The author described a method of distribution on a three-wire system from a single dynamo, and which was illustrated in your journal on April 13. It is, of course, well known that to establish a three-wire system, a neutral point must be created in the generating system, and to which the compensating wire is connected. It is in the formation of this neutral point that the originality of the system described lies.

Instead of joining two dynamos in series to obtain this result, there are connected to two points diametrically opposed of the armature the two extremities of a coil, having great self-induction and a feeble ohmic resistance. During the rotation of the armature there will be produced between the points an alternating E.M.F.; but as the coefficient of self-induction of the system has a great value, the alternating current created in the circuit will be weak. It is possible to reduce the intensity of this current as much as desired by increasing the coefficient of self-induction of the coil, which can easily be done by arranging it on a core closed in iron.

If the compensating wire, by which the groups of lamps are connected in series, is placed into communication with the neutral point, and if the "bridges" used contain in operation the same number of lamps or apparatus, the neutral wire will remain without current. But if No. 1 "bridge" is loaded more than No. 2, the excess of current of the first over the second will return to the dynamo by the compensating wire, and, reaching one point, this current will be divided. As it is continuous, it will have no difficulty in traversing the coil mentioned so as to penetrate the armature. By the aid of this device, exactly the same conditions as in the case of the use of two generators arranged in series are obtained. The independence of the two consuming groups is complete, and if one or other of these groups consumes more current than the other, the pressures remain the same, since the excess of the current returns to the armature without any loss by the neutral wire and by the coil.

As it is not always practicably possible to revolve the coil with the armature of the dynamo, two diametrically opposed segments of the commutator can be respectively connected to two rings on the shaft, and upon which press two brushes placed in communication with the two extremities of the coil. This coil, which in this case is fixed, is arranged in a box at the side of the dynamo, and always has, as in the preceding case, its neutral point connected to the compensating wire. This method can be employed for the purpose of regulating the pressure, especially in the case where the central station is distant, and supplies current at a pressure equal to the total tension of the two groups of lamps. In this case it is only necessary to insert near the places of utilisation one or several of these dynamos provided with self-induction bobbins. The brushes are put into communication with the main conductors in such a manner that the armature commences to revolve and works as a motor; the neutral wire has not to be connected to the central station situated some distance away, and it then only serves for the compensation of the two circuits in use.

Concluding Proceedings.

Herr E. Naglo, in the course of the proceedings, brought forward the question of tendering for contracts. As a result of this communication the union resolved to appoint a commission to make proposals with a view to devising a method of avoiding the misunderstandings which arise in the invitations for tenders, especially in regard to the working out of costs and schemes.

Herr Carl Dihlmann's motion that the commission nominated for the purpose of introducing a standard size of contacts and screws should be allowed to quietly continue its labours, was adopted.

A discussion having taken place in regard to the Bill proposing certain exceptions to Sunday labour, it was unanimously decided to hold the next annual meeting in Munich in the middle of 1896.

Dr. Slaby having been re-elected president, with Herren Wilhelm von Siemens, Oskar von Miller, and C. Hartmann and Prof. W. Dietrich and Herr Kolle as vice-presidents, the proceedings terminated in a dinner given in the Central Hall.

Mix and Genest.—The new factory of Messrs. Mix and Genest now being built in Bülowstrasse, Berlin, will be completed in October.

PHYSICAL UNITS.

BY MAGNUS MACLEAN, M.A., F.R.S.E.

(All Rights Reserved.)

(Continued from page 683.)

§ 9. The unit of time universally employed is a mean solar second. The reader should notice that this unit of time differs from a solar second and from a sidereal second. A sidereal day is the time that elapses between two successive transits of any fixed star at any chosen meridian, or it is the time of the earth's rotation on its own axis. A sidereal second is, therefore, the time that the earth takes to rotate through an angle of one two-hundred and fortieth of a degree.*

§ 10. A solar day is defined as the time that elapses between two successive transits of the sun at any given place on the earth's surface. For two reasons this time is of variable length. Firstly, the path of the earth round the sun is an ellipse, and hence its motion is sometimes quicker and sometimes slower. Secondly, the motion of the earth is in the plane of the ecliptic and not in the plane of the equator.

§ 11. To understand the first cause, Newton's universal law of attraction will help us: "Every particle in the universe attracts every other particle with a force which is proportional to the product of the masses of the two particles directly, and to the square of the distance between them inversely." Take two uniform spheres of masses, m and m^1, and let the distance between their centres be d, then the force of attraction between them is $F = k\frac{m\,m^1}{d^2}$, where k is the mutual force of gravitational attraction between unit masses at unit distance, and its value is calculated below for both the metric and British units.

Now, the mass of the earth is $6{\cdot}14 \times 10^{27}$ grammes, and the radius of it is approximately 637×10^6 centimetres. Hence, if we take the force of gravity on one gramme to be 980 dynes, we get $k = \frac{980 \times (637 \times 10^6)^2}{6{\cdot}14 \times 10^{27}} = 64{\cdot}8 \times 10^{-9}$ dyne $= \frac{1}{15{\cdot}43 \times 10^6}$ dyne.

The force with which two homogeneous spheres of matter of one gramme would attract one another, when their centres are 1cm. apart, is approximately a fifteen-millionth part of a dyne. To find out what would be the mass of two spheres† that would attract with the force of one dyne, when their centres are 1cm. apart, we have $F = 1$, $m = m^1$, and $d = 1$, $\therefore m = \sqrt{1/k} = 3{,}928$ grammes.

If we take the British units

$$k = \frac{32 \times (21 \times 10^6)^2}{13{\cdot}5 \times 10^{24}} = \frac{1}{965{\cdot}7 \times 10^6} \text{ poundal,}$$

and a calculation similar to the above gives the masses that would have one foot apart (see footnote as to a practical problem), a mutual force of attraction of one poundal, as 31,075lb.

§ 12. Let Fig. (1) represent an ellipse, S the sun in one focus, and E the earth. The earth when at A^1 is about three million miles nearer the sun than when at A. Hence the velocity of the earth at A^1* is greater than the velocity at A. In passing from A^1 to A the velocity of the earth is continually decreasing, and in passing from A to A^1 it is continually increasing. (The average velocity of the earth in its path is approximately 18½ miles per second.) At A^1 when the earth is in the winter solstice of the northern hemisphere, the solar day is longer than when it is at A in the summer solstice. That is, a solar day in mid-winter is longer than a solar day in mid-summer. In the further understanding of this fact, one of Kepler's three laws of planetary motion is of great help: "The radius vector of any planet sweeps over equal areas in equal times." In the figure, if the earth takes the same time to pass from A to B as from A^1 to B^1, then area S A B is equal to the area S A^1 B^1.

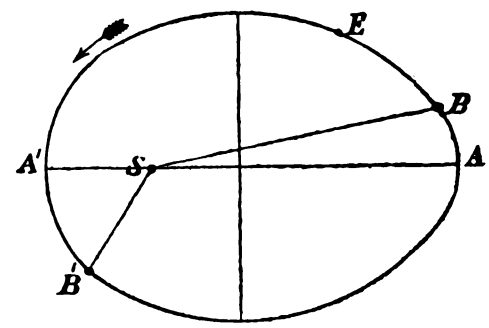

FIG. 1.

The other two laws of Kepler, though not necessary to the present discussion, may be stated here: "The planets revolve in ellipses around the sun, and the centre of the sun occupies one of the foci."

"The squares of the periodic times of any two planets have the same ratio as the cubes of their maximum (mean) distances from the sun."

§ 13. These three laws are purely kinematical. Their dynamical interpretation was discovered by Newton. From the law that the areas swept over by the vector drawn from the sun to a planet are proportional to the times of describing them, Newton inferred that the direction of the force acting must always pass through the sun.

From the law that the orbit of a planet with respect to the sun is an ellipse—the sun being in one of the foci—and, in conjunction with the previous law, Newton inferred that the magnitude of the force acting is inversely as the square of the distance from the sun.

From the law that the squares of the periodic times of different planets are proportional to the cubes of their mean distances, Newton inferred that at the same distance gravity acts equally on equal masses of substances of all kinds.

§ 14. The second cause of the variable length of the solar day is that the apparent motion of the sun, or the real motion of the earth, is in the plane of the ecliptic, and not in the plane of the equator. The angle between the plane of the equator and the plane of the ecliptic is nearly 23½deg. The points in which the sun in his apparent motion cuts the plane of the celestial equator are called nodes. If we suppose an imaginary sun to start from one

* "In our first edition it was stated in this section that Laplace had calculated from ancient observations of eclipses that the period of the earth's rotation about its axis had not altered by 1/10⁷ of itself since 720 B.C. In § 830 it was pointed out that this conclusion is overthrown by farther information from "Physical Astronomy" acquired in the interval between the printing of the two sections, in virtue of a correction which Adams had made as early as 1863 upon Laplace's dynamical investigation of an acceleration of the moon's mean motion, produced by the sun's attraction, showing that only about half of the observed acceleration of the moon's mean motion relatively to the angular velocity of the earth's rotation was accounted for by this cause. (Quoting from the first edition, § 830.) "In 1859 Adams communicated to Delaunay his final result—that at the end of a century the moon is 5″·7 before the position she would have, relatively to a meridian of the earth, according to the angular velocities of the two motions, at the beginning of the century, and the acceleration of moon's motion truly calculated from the various disturbing causes then recognised. Delaunay soon after verified this result, and about the beginning of 1866 suggested that the true explanation may be a retardation of the earth's rotation by tidal friction. Using this hypothesis, and allowing for the consequent retardation of the moon's mean motion by tidal reaction (§ 276), Adams, in an estimate which he has communicated to us, founded on the rough assumption that the parts of the earth's retardation due to solar and lunar tides are as the squares of the respective tide-generating forces, finds 22ˢ. as the error by which the earth would in a century get behind a perfect clock rated at the beginning of the century. If the retardation of rate giving this integral effect were uniform (§ 35, *b*), the earth, as a timekeeper, would be going slower by ·22 of a second per year in the middle, or ·44 of a second per year at the end, than at the beginning of a century." Thomson and Tait, "Treatise on Natural Philosophy"; footnote to § 405, page 460.

† The word sphere is used intentionally, for a uniform sphere attracts external matter as if its whole mass were concentrated at its centre. The problem in the text is unrealisable in practice, but it can be asked what would be the mass of each sphere to have a mutual force of one-hundredth of a dyne, when their centres are 10cm. apart. Thus a sphere of gold weighing 3,928 grammes would be 3·65cm. in radius.

* Centrifugal force is also greater at A^1, but a complete discussion of the problem is not attempted here. The velocity at any point is inversely proportional to the perpendicular from S to the tangent at that point.

Digitized by Google

of these nodes at the same time as the actual sun, and to move in the equator with such a uniform velocity as to arrive at the node again at the same instant as the real sun, then time indicated by this imaginary sun is mean solar time. Mean solar second is $\frac{1}{86400}$ of a mean solar day. A solar day is 3 minutes 56 seconds, or nearly four mean solar minutes longer than a sidereal day. Further information on this important subject ought to be obtained by referring to any modern text-book on astronomy.

§ 15. It is evident from § 8 that the choice of a definite length and of a definite mass, as two of the fundamental units, fulfils the most important considerations necessary in their selection. It should be possible to compare them easily, directly, and accurately with other quantities of the same kind, and this at all times and at all places.

§ 16. The unit of time is subject to a slow variation (see footnote § 9), and hence other fundamental units of time have been suggested. In Thomson and Tait's "Natural Philosophy," vol. i., § 406, page 461, the period of vibration of a metallic spring kept at a constant temperature in an exhausted and a hermetically sealed glass vessel is suggested, and the statement is made that "it would almost certainly be more constant from age to age than the time of rotation of the earth (cooling and shrinking, as it certainly is, to an extent that must be very considerable in fifty million years)." In § 223, page 226, it is said that "the period of vibration of a piece of quartz crystal of specified shape and size, and at a stated temperature (a tuning-fork, or bar, as one of the bars of glass used in the 'musical glasses') gives us a unit of time which is constant through all space and all time, and independent of the earth." Other two units of time are suggested in the same article—viz., (1) the time of revolution of an infinitesimal satellite close to the surface of a globe of water, at standard density; and (2) the time of the gravest simple harmonic infinitesimal vibration of the same globe. It is shown that both these units are independent of the size of the globe. Lastly, it has been suggested that the time of vibration of some widely diffused substance, such as sodium or hydrogen, might be taken as the unit of time, and that its wave-length in vacuum might be taken as the unit of length.

"The recent discoveries due to the kinetic theory of gases and to spectrum analysis (especially when it is applied to the light of the heavenly bodies) indicate to us *natural standard* pieces of matter, such as atoms of hydrogen, or sodium, ready made in infinite numbers, all absolutely alike in every physical property. The time of vibration of a sodium particle corresponding to any one of its modes of vibration is known to be absolutely independent of its position in the universe, and it will probably remain the same so long as the particle itself exists. The wave-length for that particular ray—*i.e.*, the space through which light is propagated *in vacuo* during the time of one complete vibration of this period—gives a perfectly invariable unit of length; and it is possible that at some not very distant day the mass of such a sodium particle may be employed as a natural standard for the remaining fundamental unit."*

ON AN APPARATUS FOR THE MEASUREMENT OF COEFFICIENTS OF SELF-INDUCTION, AND THE INVESTIGATION OF THE PHENOMENA OF ALTERNATING CURRENTS.†

BY FRANK A. LAWS.

The increasing use of alternating currents in telephony and electric lighting has during the last few years directed attention to the measurement of coefficients of self induction. In this paper certain apparatus devised for this purpose, together with methods for its use, will be described. Further discussion of the various methods of measurement proposed and of experimental results obtained is reserved for a later article.

For investigations pertaining to telephony it is particularly desirable to measure inductances by means of alternating currents of suitable known frequencies, and of the same order of magnitude as those used in practice. In all such work the reduction of the results is greatly simplified if the E.M.F. employed follows the sinusoidal law.

Therefore the aim at the outset was to produce a dynamo whose E.M.F. should vary in this manner, and whose frequency of alternation should be about that which is normal in telephonic work. Under these requirements there have been designed in the Rogers laboratory two dynamos, or arrangements of dynamos. The first of these was planned during the winter 1890-91, and was used by Mr. L. Derr in connection with his thesis in 1891-92. This machine was provided with a stationary armature having Lord Kelvin's zigzag winding on the outer surface of a hollow cylinder. This was placed in the gap between a star-shaped piece of iron and a disc with a corresponding star-shaped opening, the two pieces being similarly and concentrically placed and forming the pole-pieces of the machine. Owing to the shape of the pole-pieces, the field between them is variable, being denser at the points of the stars, so that when the field moves past the armature an E.M.F. will be set up in the latter.

One disadvantage of this design is that the E.M.F. is small, owing to the very large non-effective field, for it is only the variation of the field that is of service in producing the E.M.F. By properly shaping the pole-pieces a curve of E.M.F. was obtained, which when plotted was found to be nearly sinusoidal in form.

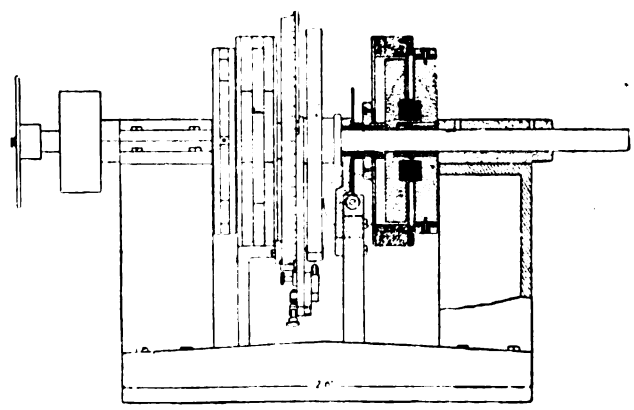

FIG. 1.

The second machine was constructed by Messrs. C. L. Norton and P. H. Thomas, of the class of 1893, and forms the subject of the present paper. The special form of dynamo used was designed in accordance with a suggestion from them. The frequency is somewhat low, being 400 complete alternations per second. When another machine is built it will be so designed that the superior limit will be raised to 2,000 complete periods per second.

Both the machine of 1890 and that of 1892 embody the same general features. Each has two independent armatures—one fixed, the other movable in phase relation to the first. This relation is capable of measurement. At the outset it was determined that in these machines the armatures should contain no iron, and that they should remain stationary, in order to eliminate any possible microphonic action at the brushes.

The machine consists, in brief, of two dynamos, with revolving fields mounted on one shaft to ensure definite phase relation. The armature of one is fixed, while that of the other may be given any desired angular advance or retardation in reference to the first by means of a tangent screw. This advance can be read off from the graduated head of the screw. The fields are independent of one another. In addition to the dynamos the shaft carries a contact arrangement for mapping wave forms, and a stroboscopic disc for determining the speed of rotation.

One of the field magnets is shown in plan in Fig. 2 and in section in Fig. 1. It consists of two star-shaped pieces of cast iron, keyed to the shaft and having hubs of such a

length that the faces of the teeth are $\frac{5}{16}$in. apart, thus leaving a gap in which is the armature, $\frac{1}{4}$in. thick. The castings are recessed to receive the field coils, which are about one square inch in section and contain 250 turns of No. 16 B. & S. double cotton-covered wire. The coils were wound on forms, paraffined and taped, and were inserted when the machine was assembled. The terminals are brought out through bushed holes and fastened to composition collector rings, which are carried and insulated by blocks

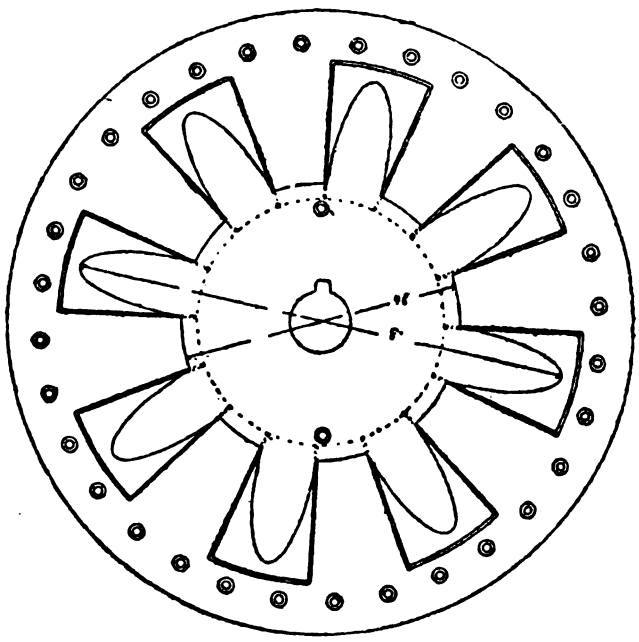

FIG. 2.

of vulcanite mounted on the tips of the teeth of one of the castings. The brushes of spring copper are supported from the base-plate. The eight teeth were milled from the round by a special Brown and Sharpe cutter, and have the form of a sinusoid laid off radially from the base circle. Of course, owing to the spreading of the lines of force, the particular form to be given to the teeth in order to obtain the best action can only be ascertained by trial.

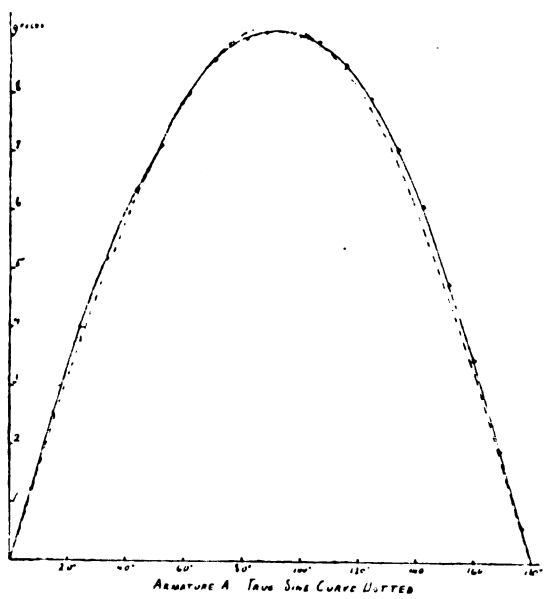

FIG. 3.

The armature consists of a vulcanite disc, 10$\frac{1}{2}$in. diameter, $\frac{1}{4}$in. thick, having a 4in. hole in the middle. From this hole radiate 16 equally spaced saw-cuts $\frac{3}{16}$in. deep, $\frac{1}{16}$in. wide, and 2$\frac{1}{2}$in. long, the outer extremities of alternate pairs of cuts being connected by grooves concentric with the disc. In these cuts and grooves the armature wires are laid in shellac. The windings at present consist of three sections having respectively 10, 10, and 20 turns of No. 30 B. & S. copper wire. The total resistance is about 10 ohms. The manner of winding, as well as the action of the dynamo, by varying the length of active wire, are evident from Fig. 3. The armatures are carried by built up hardwood rings, 10$\frac{1}{2}$in. outside diameter, 8$\frac{1}{4}$in. inside, and 1$\frac{9}{16}$in. deep. The ring in one dynamo is attached to a brass disc and hub, which fit the shaft and are rigidly bolted to the frame of the machine.

In the other dynamo, the armature, ring, disc, and hub are attached to a worm-wheel, and the whole is movable on a sleeve supported firmly from the frame of the machine. Through this sleeve passes the shaft without contact. The worm-wheel gears into a tangent screw provided with a divided head, the gearing being such that 1deg. on the wave form is represented by 20deg. on the head. Backlash is prevented by a spiral spring. See Figures 1 and 2.

Between the two dynamos is a brass disc, keyed to the shaft and provided with an insulated collector ring and contact point. By the side of this disc is a radial arm, revolving freely about the shaft, and capable of being clamped at any desired point to a fixed graduated circle. The arm carries the contact spring, made of watch-spring supported on its lower side very near its extremity to prevent the lengthening of the arc of contact by vibration. The spring can be moved out of contact with the point by a fine-pitched screw. This contact arrangement we have found to work satisfactorily at as many as 3,000 revolutions per minute.

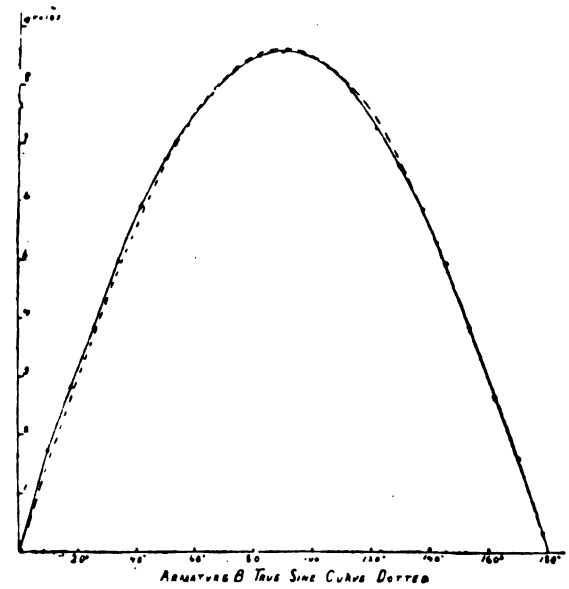

FIG. 4.

The shaft of the machine is of steel, 1in. in diameter, 29in. long, and runs in composition bearings, each of which is 5$\frac{1}{2}$in. long. The frame of the machine is heavy, weighing 175lb., and is designed so as to be very rigid. Driving is effected by means of a 2in. belt running over a 5in. pulley. The motor (1 h.p.) is of the Sprague type. Variations of speed are obtained by the use of pulleys of different sizes on the motor shaft.

Both machine and motor rest on a brick pier, the machine being set in sulphur; mechanically, the arrangement leaves nothing to be desired. It has been run continuously at the rate of 3,000 revolutions per minute, without perceptible jarring.

The machine was at first supplied with a mechanical counter, which could be thrown on or off by means of an electromagnet operated by a key. We found, however, that the arrangement was unsatisfactory, as variations of speed were introduced by its friction and inertia. Moreover, such an arrangement gives only the average speed during a given time; we therefore abandoned this counter and adopted a stroboscopic device. A ray of light is reflected upon the revolving segmented disc from a mirror attached to an electrically driven tuning-fork of known rate. With such an arrangement the desired speed may be attained, and variations from it measured by noting the apparent motion of the disc.

The first test to which the apparatus was put was to obtain the judgment of a person having a trained ear as to the quality of the tone produced by its current in a

Digitized by Google

telephone. His opinion was that the tone was pure, only the fundamental being detected. The wave form was then mapped.

In planning this work it occurred to us to employ the method of projection of potential whenever it was necessary to measure a P.D. or E.M.F. at any instant. The opposing P.D. was obtained by the fall of potential due to the passage of a direct current through a suitable resistance. As the opposing P.D. was not alternating, the above-mentioned contact arrangement was used in place of the ordinary key, and its value was determined by a suitable Weston voltmeter. This method of dealing with instantaneous E.M.F.'s was originally suggested by Profs. Foster and Maxwell, their object being to obtain a balance between a known E.M.F. and the P.D. between the terminals of a resistance through which a current of known absolute magnitude was flowing.*

In order to obtain sensitiveness at the final balancing, a condenser one microfarad in capacity was inserted in shunt with the galvanometer, the discharge of the condenser serving to increase the deflection. The galvanometer was of 3,000 ohms resistance. A telephone was used to obtain the preliminary balance. In Table I. are given the results of the determination of the wave forms of both dynamos, one section of 10 wires being used. In the case of armature A (movable) a series of checks is appended. The whole series was gone through with, and then repeated in the reverse direction, the person making the readings not knowing the previous results. The most probable sources of deviation are back-lash, variations of field current, and change of speed. The checks show sufficient precision of the apparatus for the method of procedure to be described presently.

These results are plotted together with true sine curves in Figs. 3 and 4. The curves proved to be very nearly symmetrical, so that only one half has been given. The saturation curve connecting maximum E.M.F. and field current was taken with armature A. The results are given below, and are plotted in Fig. 5.

METHODS OF USING THE MACHINE.

The following methods are all based on the assumption that we have a sinusoidal E.M.F. of known period, acting in a circuit containing only true resistances and inductances. The current at any instant will be expressed by the equation

$$i = \frac{E}{\sqrt{R^2 + P^2 L^2}} \sin\left(P t - \tan^{-1}\frac{LP}{R}\right).$$

The maximum value of the sine term being unity, we have

$$\frac{I}{E} = \frac{1}{\sqrt{R^2 + P^2 L^2}},$$

I and E being the maximum current in, and maximum E.M.F. impressed upon, the part of the circuit under discussion. Also the lag between current and E.M.F. is expressed by $\tan\theta = \frac{LP}{R}$. From these two equations we have

$$L = \frac{E}{IP}\sin\theta, \quad \text{and } R = \frac{E}{I}\cos\theta.$$

Our aim is, therefore, to obtain the values of the impedance, angle of lag, and frequency, and to calculate the coefficient of self-induction and the resistance for any given periodicity by the above formulæ.

(*a*) If we make up a circuit of the movable armature, a known resistance of negligible inductance, and the unknown coil, all in series, we may, by means of the measuring arrangement already mentioned, obtain E and I, the latter by the maximum P.D. around the known resistance. The angle θ would best be found by taking measurements on both sides of the zeros of current and E.M.F., and interpolating for the zero points. The difference of readings of the micrometer so obtained divided by 20 gives the angle θ. L and R are to be calculated by the above formulæ.

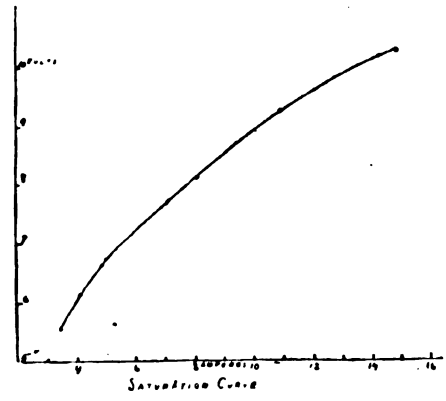

FIG. 5.

(*b*) If we have a carefully made plot, like Fig. 5, connecting the maximum E.M.F. and field current of one dynamo, we may proceed as follows. As the wave forms are alike, both following the sinusoidal law, we may apply Poggendorf's method of balancing E.M.F.'s directly, using a suitable telephone instead of a galvanometer. To do this make up a circuit of the stationary armature, known inductionless resistance, and unknown coil. Keep the field current of this dynamo constant. Attach the second armature through the telephone, first to the terminals of the known resistance. Adjust the phase relation for a minimum of sound in the telephone; then adjust for silence by varying the field current. Read the micrometer head and value of exciting current. Repeat this process at the terminals of the unknown coil. These measurements furnish the data necessary for the calculation of L and R. θ is given by difference of micrometer readings divided by 20, as before. Owing to lack of exact similarity of E.M.F. waves it would be necessary in practice to adjust by a minimum, annulling the fundamental.

(*c*) The trouble of taking the preliminary curve, as well as any uncertainty which its use may introduce, can be avoided by the connections shown in Fig. 6.

This method differs from the preceding only in the use

Digitized by Google

of a derived E.M.F. for balancing, and in the method of its adjustment. For convenience give R_1 such a value that the P.D.'s around R_1 and R shall be about equal. Adjust the phase of armature A by the tangent screw, and adjust for amplitude by varying the field current, final adjustment being obtained by the slider.

Now change the connection to the terminals of the unknown coil, and again adjust for silence, making the adjustment for amplitude in this case by the slider alone. If the two values of the slider resistance are R_2 and R_3, then $\frac{I}{E} = \frac{R_2}{R_1 R_3}$. θ is given by the micrometer head as before.

(*d*) We may use a differential telephone—that is, a telephone having two opposed windings of equal influence and resistance, in the manner shown in Fig. 7.

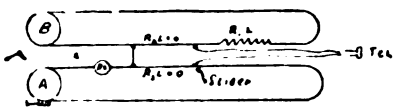

FIG. 6.

R_T is a resistance equal to that of one coil of the telephone and of negligible inductance. Adjustment is to be made until with the same value of i_A the telephone is silent when in place, as shown, and when interchange with R_T, then $R_1 = \frac{E}{I}$. θ is given by micrometer readings as before.

(*e*) We may also use the differential telephone to indicate when an unknown inductance is neutralised by a condenser of known variable capacity by placing one of its coils in series with the inductance and condenser, and the other in series with a variable inductionless resistance, R_1, shunted around the above condenser, inductance, and telephone coil, if the resistance, R_1, and capacity, C, be varied until silence is obtained. Then $L = \frac{1}{C P^2}$ and $R = R_1$. It will be desirable to employ an air-condenser to eliminate absorption effects, though this procedure has the disadvantage of requiring a very bulky and costly condenser when small inductances are to be measured.

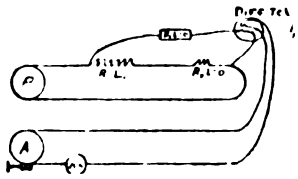

FIG. 7.

With this apparatus we may also determine the electrostatic capacity of a condenser when not complicated by absorption effects. For instance, by the first method we should insert in series with the condenser an inductionless resistance of such a magnitude that the angle of advance could be determined with accuracy.

Then $\frac{I}{E} = \frac{1}{\sqrt{R^2 + \frac{1}{C^2 P^2}}}$, $\tan \psi = \frac{1}{C R P}$,

$$C = \frac{I}{E P \sin \psi}, \text{ and } R = \frac{E}{I} \cos \psi.$$

If $R = 0$, $\psi = 90$deg, and $C = \frac{I}{E P}$.

The above are the chief uses to which the apparatus may be put.

We hope in the near future to investigate the transmission of telephonic and telegraphic signals, and to study various small induction coils such as are used in telephony, as well as the errors introduced into results by the above methods owing to lack of fulfilment of the assumed law by the E.M.F.

THE GRASSOT ELECTRICITY METER.

This type of meter is described in the current issue of *L'Industrie Electrique*. A general view of the apparatus is given in Fig. 1, and a diagrammatic sketch in Fig. 2. Our contemporary says:

"Let us suppose a silver wire, *f*, is perfectly calibrated, and that the lower point is made in the form of a cone. We will place this wire in a vertical position, the lower point resting upon a glass plate, *a*, lightly dipped in a solution of nitrate of silver, and arrange on the upper end of the wire a mass, *p*, the object of which is to depress the lower point on to the glass plate. In these circumstances, if we pass a current through a part or the whole of the wire, leading in the current through *m* by means of a spring, S, which presses upon the wire, and by making it come out by a silver electrode, *e*, after having traversed the solution of nitrate of silver, the lower part of the wire, *f*, will be worn to an extent proportional to the quantity of current which has traversed it. We shall then be able to measure the quantity of electricity that has passed through the wire by the wear of this wire.

"In order to show this wear, and to allow of its being measured, the meter is arranged in the following manner:

"The silver wire, *f*, is led into a glass tube, into the interior of which the mass, *p*, can slide. It is pressed by a multiple contact spring, S, the same that brings the current on a roller, G, of a determined diameter. In the descending movement of the wire, the roller, G, is drawn away. If, then, we arrange on the axis of this roller a needle,

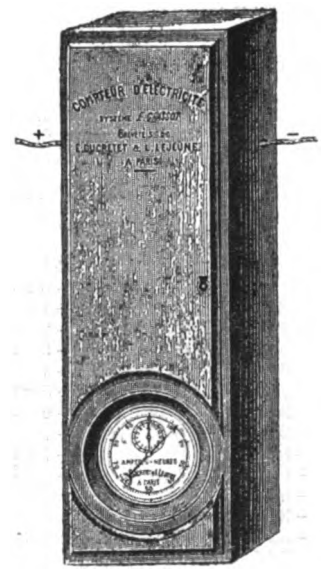

FIG. 1.

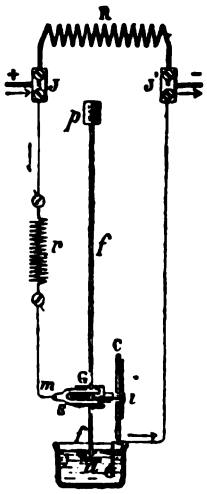

FIG. 2.

i, moving in front of a divided dial, C, we shall be able to graduate the dial in ampere-hours, and we shall thus obtain a meter of extremely simple intensity, and of assured working.

"In practice, only a determined fraction of the current is passed through the silver wire. For this purpose, there is arranged between the terminals, J and J', of the meter a weak resistance, R, and between its terminals the meter proper is placed in shunt with a great additional resistance, *r*. The resistance of the electrolytic bath being very weak, it may be said that the current is divided between the two circuits in the inverse ratio of the resistances, R and *r*; the graduation of the dial is consequently established. By this means a too rapid wear of the silver wire is avoided. The silver contained in the wire is not lost; it is found integrally upon the electrode, *e*. The apparatus is arranged in a box, which is provided with rubbing springs establishing contact with the meter.

"Let us now see the working conditions of the meter. For the meter of a maximum of three amperes $R = 0{\cdot}4$ ohm, and $r = 2{,}750$ ohms. Under these circumstances the errors are as follows:

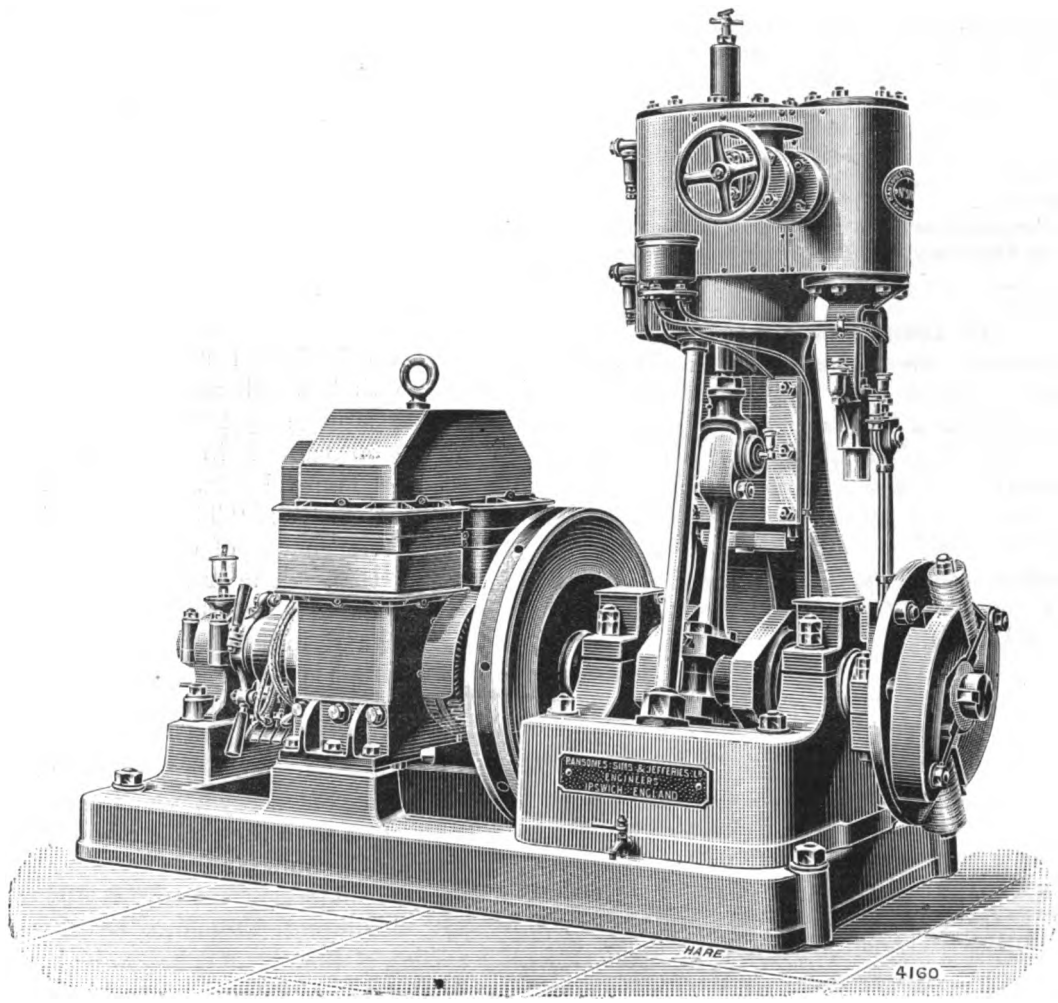
Discharge in amperes.	Percentage of error.
·5	6
1·5	2
3	0

Digitized by Google

"These errors," *L'Industrie Electrique* concludes, "may be regarded as negligible in practice, and the meter may be advantageously used in installations of from one to six lamps."

COMBINED HIGH-SPEED ENGINE AND DYNAMO.

In the accompanying illustration is shown a combination which has recently been introduced by Messrs. Ransomes, Sims, and Jefferies, Limited, of Ipswich, and 9, Gracechurch-street, E.C. The engine has been designed purposely for operating dynamos, pumps, centrifugal fans, and other kinds of machinery driven at high speeds, either direct coupled or operated by belt, and it is particularly applicable for ship-lighting. The combination, as will be seen from the illustration, forms a neat and compact arrangement; the engine is double acting, the construction being that known as the "open" type. The engraving shows the general design of the engine, which can be built with the valve-chest and flywheel reversed in position if required.



A very high boiler pressure and an ample margin of safety have been allowed for in calculating the strengths and wearing surfaces of the various parts; and while such a course is not recommended, these engines may be worked direct from the boilers of triple-expansion engines without risk of breakdown or heating. The reciprocating parts are all accurately balanced. The cross-head is of cast steel, and the gudgeon is so fitted that the loosening of one nut and a slight tap will release it, and admit of the examination of the brasses. The cross-head gudgeon and the crank-pin are both of very large diameter, and the width of each of these bearings is equivalent to twice the diameter; the shaft bearings are also of exceptional size. The bearings are provided with screw adjustments, and are accessible without the slightest difficulty. The lubrication of the working parts is effected automatically, and is continuous; the cylinder is provided with a self-acting cup, and the crank-pin is fitted with a centrifugal oiler. This oiler and the cups at the top ends of the rods are supplied from a central oil-box placed in a convenient position and provided with a sight-feed arrangement to each supply pipe. A wrought iron splash-guard, which is not shown in the illustration, is provided.

The engine shown in the illustration is fitted with an automatic expansion shaft governor, which acts direct upon the piston slide-valve and varies the cut-off in proportion to the load. If preferred, a throttle-valve governor on the Pickering principle may be used instead of the shaft governor. The speed can be adjusted as may be desired while the engine is running with the Pickering governor, and a special patent attachment can be provided with the shaft governor to attain the same object. The engine has a cylinder 8½in. diameter by 8in. stroke. It is coupled to a dynamo made by Messrs. Laurence, Scott, and Co., of Norwich. The output is 180 amperes at 65 volts when running at 270 revolutions. The field magnets are constructed of special magnet steel cast in one piece. The armature is built up in the usual way with charcoal iron discs, each of which is driven in by three keys from the shaft. The conductors, which are of pure copper strip well insulated with mica, are let into slots milled in the discs. By this means an extremely strong mechanical job is made, whilst at the same time the magnetic and electrical difficulties that were at one time involved in these slotted armatures have been entirely overcome by correct proportioning of the different parts. Sparking at the commutator and the excessive lead required for the brushes have been entirely obviated by careful design, and by means of the electrical company's patent pole-pieces, the lead required up to half load being 0 and only 7½deg. for full load.

This type of engine is manufactured by Messrs. Ransomes, Sims, and Jefferies in six standard sizes. A considerable number of engines and several combined engines and dynamos have already been supplied, and are giving great satisfaction.

BOUND VOLUMES.

Vol. XII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

REFUSE DESTRUCTORS.

The idea that by using a refuse destructor sufficient waste heat can be obtained to provide for electric lighting has entered the minds of many town councillors, and will be difficult to correct. It is the interest of new destructor designers, patentees, and constructors to make everything connected therewith appear as rosy as possible. The recent issue of Mr. Jones's book on "Refuse Destructors," and Prof. Unwin's "On the Development and Transmission of Power," may provide food for consideration. Let us take Prof. Unwin's views. He estimates the refuse to be destroyed in destructors as amounting to "from one hundred tons to four hundred tons per hundred inhabitants per annum." Take the lower figure, which gives one ton per year per inhabitant. Further, it is estimated that we may get "eighty-eight effective horse-power from six cells burning a total of one and a half tons of refuse per hour. This is about forty pounds of refuse to the effective horse-power hour." With these figures as a starting point we get the destruction of thirty-six tons of refuse per day, or just over twelve thousand tons a year. At the ton per man per year rate, this means the destruction of the refuse of a town of twelve thousand inhabitants. From such destruction we should get one hundred and seventy-six effective horse-power, so that it will at once be seen that, without some storage system, this amount of energy would be altogether inadequate to supply both street and house lights. But Prof. Unwin goes further. He says: "The chief difficulty in using the available energy of destructors for power purposes is this. The refuse must be burned at a nearly regular rate. But demands for power are fluctuating and intermittent. Presently, a method of heat storage is to be described which overcomes this difficulty. The adoption of such a method would render the utilisation of the waste heat of destructors much more practicable, and would give to this source of energy a much greater importance in connection with the problem of distributing power in towns. Of course, refuse is a very poor fuel, and there is considerable expense in labour in burning it. It would not, therefore, be chosen as a fuel for raising steam. But it has to be burned for sanitary reasons. If any profit can be made by utilising the heat, that is a gain. The cost of the power obtained is merely the interest on the cost of the boilers and appliances which have to be added to the destructor, in order to utilise the heat which would otherwise be wasted."

That is a clear statement, and should never be forgotten. The first object of a destructor is a sanitary one, and it must fulfil this object at all costs. If, without detracting from its efficiency as a sanitary engine, we can utilise the waste heat for lighting purposes, so far so good. We are glad also to read Prof. Unwin's remark that "refuse is a very poor fuel," because interested parties are trying to induce town councillors to believe that refuse is as good a fuel as ordinary coal. This attempt may seem improbable to those who do not fully comprehend the wiles of inventors—

Digitized by Google

but such is the fact, and only the other day the question was being discussed by a number of municipal engineers whose statements, if heard, might possibly have shamed some of those whose talk is tall and whose statements are not made with a rigid adherence to accuracy. Before referring to storage, it may be as well to see how far the maximum of four tons of refuse per inhabitant per year would go to provide light. Taking forty pounds of refuse as giving an effective horse-power hour, four tons would give two hundred and twenty-four horse-power hours, and this spread over three hundred and sixty-five days would give less than three-quarter horse-power hour per day per head of population. Under these, the best conditions with an average household of five persons, we should get three and three-quarter horse-power hours per day per house, which, under the doctrine of averages, might be deemed sufficient to provide light. We think, however, when the total population is considered, that the average refuse would be much nearer the minimum adopted above than the maximum. All agree upon one point, and that is, where destructors are used there must be a considerable amount of waste heat. This arises from the fact that the escaping gases must be at a high temperature. How much heat and how may it be effectually used is the problem for consideration. Properly fired, the waste heat should be far more constant than the demand for lighting or power purposes would require; hence, if this constant product could be effectively and economically stored, municipal authorities might at any rate obtain a fair start for their lighting work. We consider that it is the duty of the authorities to provide all artificial light, but if their efforts are restricted to street-lighting, it is pretty safe to say that, with the waste heat from destructors at command, they could provide all required. Taking the town of twelve thousand inhabitants as supplying refuse for an effective output of one hundred and seventy-six horse-power. This multiplied by twenty-four gives over four thousand horse-power hours, and if stored for sixteen hours out of the twenty-four, with a loss of 25 per cent. would give about three thousand five hundred horse-power hours. Prof. Unwin treats two methods of storing, one by storage batteries, which he concludes is not so good as the thermal storage suggested by Mr. Druitt Halpin. We are not altogether in accord with Prof. Unwin in his conclusions on the storage problem, but it suffices now if we once more call attention to the possibilities of utilising the waste heat of destructors for lighting purposes, without admitting that even the most economical or most effective will give the whole or any particular proportion of the light required.

ROYAL SOCIETY CONVERSAZIONE.

On Wednesday evening the second or Ladies' Conversazione was held in the rooms of the Royal Society, Burlington House, when a large company was received by Lord Kelvin (president) and Lady Kelvin. Prof. Worthington and Mr. Cole, in a series of striking photographs, reproduced and extended the old experiment of Mr. Campbell, of Islay, who printed the splash of a drop from a wood block on which ink had fallen. The new experimenters employed mercury falling on a sensitive plate illuminated at the instant of impact by the spark from a Leyden jar. They also, by an adaptation of lenses, photographed the splash by reflected light. In physiological optics, Mr. Shelford Bidwell showed a new experiment, which proved one of the most attractive features of the evening. A rapidly-moving spot of green light on a dark screen was shown to be dogged at the distance of five seconds of time by a violet-tinted "ghost" When the speed of the green spot is increased, the "ghost" moves further back on the screen, and when it is reduced the violet spot approaches and coalesces with its primary. A striking novelty in the practical application of electricity was shown by Mr. T. Snedekor. It is a light quilt, which may be of any size, the interior being occupied by resistances which generate heat when a current passes, and so keep up a uniformly high temperature in the fabric for any time. Wrapped in such a sheet, one may have the effects of a Turkish bath without any special structure, and on a smaller scale the contrivance takes the place of hot poultices and fomentations. It is devised specially for hospital use. The Postmaster-General showed the Wheatstone automatic telegraphic transmitter, driven by Willmot's air motor. The air motor in this instrument dispenses with the 42lb. weight which, when the instrument is running at 600 words per minute, requires rewinding by the operator every few seconds. He also exhibited Prof. Hughes's type-printing receiving instrument, driven by Willmot's air motor, which here takes the place of the 132lb. weight previously used, and dispenses with the whole of the winding gear and nearly all the train of wheelwork, the motor being applied directly to the printing shaft. He also showed a less scientific though much more popular piece of Post Office work in the shape of a collection of curiously-addressed letters and Christmas cards. An electrical application to the transmission of writing was shown by Prof. Elisha Gray in his telautograph, by which a writer at one station, using a lead pencil attached mechanically to the apparatus, and writing upon ordinary paper, transmits to the distant station a facsimile of his handwriting at his ordinary writing speed. Sketches, sketch-portraits, diagrams, plans, trade-marks and the like, as well as the characters of hieroglyphic alphabets, may also be transmitted. Mr. J. W. Swan has produced a continuous gold-leaf by electrical deposition; the glass plates coated with it flash like yellow mirrors in reflected light, but transmit a greenish light when looked through, illustrating the perfect transparency of thin gold. In pure electricity, Prof. Oliver Lodge brought forward a compact and portable instrument for detecting electrical radiation, and a spherical radiator of short Hertz waves, with which he performed a number of experiments; and Sir David Salomons showed two new contact makers and breakers. Prof. Silvanus Thompson repeated his entertaining experiments with rotating magnetic fields, and drew crowds to see Prof. Hughes's induction balance adjusted for testing the existence of metallic plates in bullet-proof shields.—*The Times.*

THE WATERHOUSE ELECTRICITY METER.

We had last week an opportunity of inspecting a new form of electricity meter devised by Mr. Addison G. Waterhouse, an electrician whose inventions in the shape of arc lamps, etc., have for some time past achieved a measure of fame in the United States.

The appliance now under notice belongs to the class of electrolytic meters; it consists essentially of an arrangement for measuring and registering the volume of gas produced by a small fraction of the current used by the consumer. The gas is formed and measured in a glass collecting bell of somewhat novel shape, being provided with an inverted syphon tube, which discharges the gas as soon as a certain volume has been collected, and at the same time moves a registering mechanism to indicate the

Digitized by Google

number of times the collector has been filled. Fig. 1 shows the electrolytic cell, C, and the collector, B, with the inverted syphon tube, T, both being partly filled with a volume of gas, G. After the gas has accumulated until it forces the fluid down to the bend in the tube at *u*, it will start up the tube at *v*, and bubble out, leaving the bell full of fluid and ready to collect another charge of gas. At W is represented an indicating arrangement which is worked by the rise and fall of the collector, B, according as the gas collects or escapes; the vertical motion of B is thus made by means of pointers and dials to indicate the number of times B has been filled with gas.

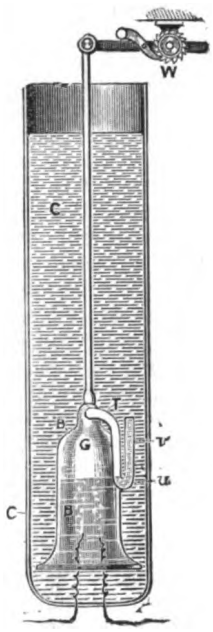

FIG. 1.

In the practical construction of such a meter, there are, says the inventor, certain difficulties to be overcome inherent to electrolytic meters in general. These are: the changes of resistance resulting from variations in temperature and specific density of the liquid used as an electrolyte; the counter E.M.F. offered by an electrolytic cell to the passage of a current through it, which in this case is about two volts, platinum electrodes in dilute sulphuric acid being used. "To meet these difficulties, we use the pressure of a derived circuit current, which, in turn, varying with the voltage on the main circuit, produces deranging effects; these, again, we overcome even to the extent that a change of 50 per cent. of voltage will not change the effect of this derived circuit, in its effect, as applied to the meter."

To explain the electrical action of this meter, reference may be made to the accompanying drawings.

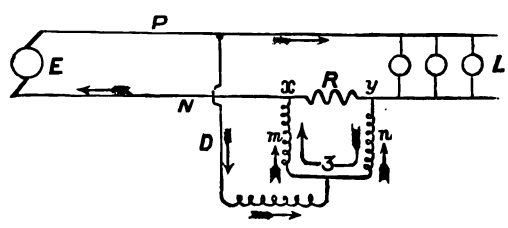

FIG. 2.

In Fig. 2, E represents the dynamo or other source of energy, and L the lamps; R is a small resistance in the main line, N, and P is the positive wire to the lamps, the difference of potential between P and N being 100 volts. A derived or shunt circuit, D, connects the mains, dividing between *m* and *n*, each branch joining wire N at the extremes of the resistance, R, or at *x* and *y*. If no current is passing to the lamps, L, none is returning through the resistance, R, and therefore there is no fall of potential between *x* and *y*; the result is that the derived circuit current starting from P to 3, and then dividing between *m* and *n* in an inverse proportion to their resistance, will mostly pass to wire N on branch *n*, as its resistance is comparatively low, and a very small part on branch *m*, as its resistance is comparatively high, and the direction of these branch currents will be as indicated by the short arrows. If a current starts to the lamps, L, and returns through R on line N, there will be a fall of potential between the extremes of R, or between *x* and *y*, which will correspond to the amount of current passing from the lamps, so as this current passes through R some of it will tend to pass around the shunt formed by *n* and *m* in the direction of the long bent arrow. This current will oppose the derived circuit current from 3 up through *n*, and compel more of it to pass up through *m*; and thus the current through *m* will increase with the change of potential between *x* and *y* due to the volume of current returning

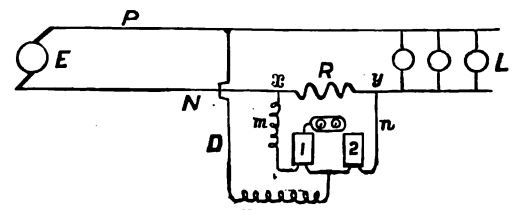

FIG. 3.

from the lamps. In order to measure the change of current in *m*, an electrolytic cell is inserted, with an arrangement, as shown, for measuring the current by the volume of gas which it evolves.

To prevent any effect due to changes of resistance caused by heat or changes in the specific density of the liquid, a similar cell, but without any measuring device, is placed in branch *n* (see Fig. 3), so that they will both be under the same conditions and mutually counteract for each other the effect of any disturbing changes. Further, in order to overcome the counter E.M.F. offered by these cells, a pressure of 100 volts is maintained through the derived circuit, D, and the changes of potential between *x* and *y* due to the main current will shift more or less current from path *n* to path *m*, being then measured and registered as shown.

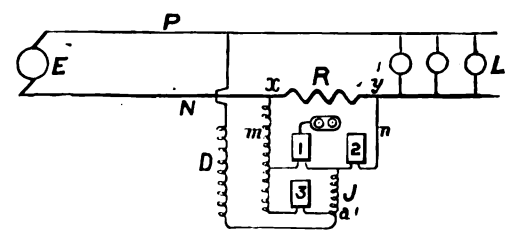

FIG. 4.

As the difference of potential between *x* and *y* is limited to ·5 volt, and the counter E.M.F. offered by cells 1 and 2 is over 4 volts, it is evident that none of the current passing through R will pass round the shunt formed by resistance *m*, cells 1 and 2, and conductor *n*; but the difference of potential between *x* and *y* caused by the current in R will cause a corresponding proportion of current to flow through cell 1 (in which it is measured by means of the gas evolved), as would otherwise flow through cell 2. The current which passes through R is measured indirectly by measuring that part of the shunt current which comes through D, and divides, so that a part will pass through the measuring cell 1 (which will correspond to the current in R). It is, therefore, plain that a constant quantity of current must flow through the derived circuit, which in common use would not be constant, owing to the changes of voltage between the main lines, P and N, and to remedy this defect use is made of a third cell, as shown in Fig 4.

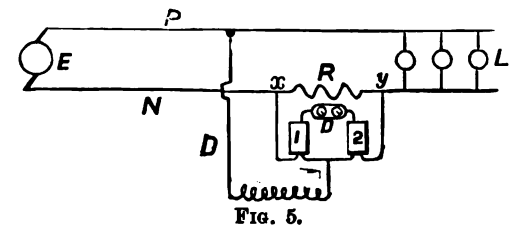

FIG. 5.

In this case cell 3 is placed as a shunt around cell 1 and the resistance, J: a complete meter is thus arranged, and if adjusted to 100 volts the derived circuit current will

Digitized by Google

divide between the cells 1, 2, and 3, and the proportion going through the measuring cell 1 will vary with the main current passing through R. Then if the voltage varies and causes more or less current to pass through the derived circuit, cell 3 will take more or less current so as to keep the amount of current which divides between cells 1 and 2 constant.

Another way of constructing this meter is shown in Fig. 5, where the floats in cells 1 and 2 mark the indicator, D, in opposite directions, so that when a very small current is passing through R the action of cell 2 will nearly counteract that of cell 1, but when the current increases in R, it will increase in cell 1 and diminish in cell 2, and the indicator, D, will show the difference due to the current in R.

This form of meter, as shown in Fig. 5, has several very important advantages over any other form, and these will probably cause it to be the type adopted. By reason of its differential action, extreme sensitiveness is attained, enabling it to take a wide margin of measurements, as it will record the current used from a small fraction of one lamp to almost any desired number; and as it contains no resistances or parts that require careful measurements, it is easy to calibrate. Changes in the voltage, it is claimed, do not materially affect this meter, owing to the fact that, as it works differentially, any change in the derived current will balance itself on both sides when no lamps are burning; and when lamps are put on, any change of current in the derived circuit, if increased, will reduce the changing-over effect of the main circuit current, on account of the increased difference of potential between the extremes of the paths through the meter, and in case of a fall of voltage opposite effects will compensate for the difference.

A special device is used in this meter (though not shown) which stops the shunt circuit current when all the lamps are turned out, and starts it as soon as one lamp is turned on.

In refilling the cells used in this meter, nothing but pure water is added after the first filling, this being repeated about once every three months.

The completed meter is contained in an oblong metal case standing 12½in. high, with index in the front reading as with a gas-meter. Three terminals are provided—two for the mains and a third for the shunt.

UNIPOLAR DYNAMOS FOR ELECTRIC LIGHT AND POWER.

A paper dealing with the above subject, by Messrs. F. B. Crocker and C. H. Parmly, was presented to the American Institute of Electrical Engineers at the recently held eleventh annual meeting. The object of the authors was to show that unipolar dynamos and motors are much more practical and generally applicable than is ordinarily supposed to be the case. The name "unipolar" was pronounced unsatisfactory, aud "continuous pole" was suggested as a good name for this type of generator. It was pointed out that iron or steel is much better than copper for the armature on account of its strength, whilst its resistance is no objection on account of the great mass of metal used. The authors described a type of unipolar machine, and adduced formula for its design. It was shown that the armature of a machine of this type for 10 volts at 1,200 revolutions need be only 24·28in. in diameter, and for 130 volts and 200 revolutions 214·4in. The capacity of the latter machine was shown by the statement that if two were coupled to the shaft of a 100,000-h.p. engine, they would develop more current than at present is consumed in any two cities of the world, and if run even as low as 1,000 h.p. the loss in the armature would only be 4 or 5 per cent. The great advantage of the unipolar machine in extreme simplicity was indicated. Its armature consists of nothing but a solid cylinder or disc of steel or other suitable metal firmly mounted upon a shaft, whilst the construction of the field magnet and the rest of the machine is also very simple. There should be, according to accepted theories, no hysteresis in these machines, no Foucault currents, and probably no armature reaction. In conclusion, the authors stated that unipolar machines are practically indestructible, since they are so simple and so strong that they are not likely to be damaged mechanically, and that it is almost impossible to conceive of one being burnt out or otherwise injured electrically, since the engine would be stalled by the enormous current before the armature could be fused by it. A machine possessing all these important advantages, they observed, certainly deserves a prominent place in electrical engineering, whereas it now has practically no existence.

A BURGLAR ALARM.

The majority of burglar alarms will be found, it is to be feared, by no means brilliantly successful in achieving the purpose for which they are designed; in fact, they are said somewhat facetiously to be handy little things for the enterprising housebreaker to pick up and put in his pocket. One will always fetch a shilling or two for use as an ordinary electric bell. Perhaps this want of success may follow from the proneness of householders to relax their efforts, allow alarms to get out of order and remain so. Indeed, there is a strong temptation at the present time to take out a burglar insurance policy and let the midnight marauders work their own sweet will. Still, there ought to be an extensive opening for electrical appliances of the kind, whether in business or private premises. If a watchman's tell-tale is worth adopting, there seems no reason why a somewhat similar appliance should not find useful service in helping the watchman. Messrs. Siemens Bros. and Co., Limited, have patented and are bringing on the market a type of burglar alarm, the special object of which is to arrange the usual contact appliance in such a position as to render it invisible and not readily accessible, besides being protected from dust and damp. This end is attained by fixing the magnet which actuates the alarm by closing or opening a circuit within the door jamb or window frame, whilst the contact lever is similarly embedded or sunk in the door frame itself, or *vice versâ*. On opening the door or window the influence of the magnet is withdrawn, and a spring or weight throws over the contact lever and completes the circuit. There does not seem any great striking novelty in this contrivance, but it doubtless offers some little improvement over those hitherto seen on the market, if only for the points mentioned.

PRACTICAL NOTES ON DYNAMO CALCULATION.—II.

BY ALFRED E. WIENER.†

(Continued from page 641.)

4. *Field Density.*—The specific strength of the magnetic field has to be chosen according to the size of the machine, the number of poles, the form of the armature, and to the material of the pole-pieces. In general, the higher a density of the magnetic lines per unit of field area is taken, the larger the output of the dynamo, and in multipolar machines greater values of $\mathfrak{B}$ are admitted than in bipolar ones. In dynamos with smooth-core armatures the field densities are greater than in those with toothed armature bodies, for in the latter a portion of the lines enters the teeth and passes through the armature without cutting the conductors; for such armatures it therefore takes more lines per square inch of pole area to produce the same field density (per square inch of area occupied by armature conductors) than for smooth cores, and consequently smaller field densities are to be taken in order to prevent over-saturation of the pole-pieces, and, eventually, of the frame. This leakage through the

* In the first section of this serial, on page 641, the symbol F has been used to denote the field density; hereafter, the symbol $\mathfrak{B}$ will be employed for the field intensity, in accordance with the congress notation of 1893. All who intend to follow this treatise are advised to make the substitutions indicating this change of notation, as reference will be made to formula (1) in future sections.

† The *Electrical World.*

Digitized by Google

armature takes place in the higher degree the greater the width of the teeth compared to that of the slots, and therefore still smaller field densities are to be chosen in case of armature cores with tangentially projecting teeth, and of those with closed slots. Finally, in machines having wrought-iron or steel pole-pieces, the densities can be taken about 50 per cent. higher than in those with cast-iron pole shoes.

2000	—	—	—	—	—	—	45000	60000	35000	50000	24000	35000

The suitable values of $\mathfrak{B}$ for all these various cases are tabulated in Table IV., which gives the average densities in lines of force per square inch, while Table V. contains the corresponding values of $\mathfrak{B}$ in lines per square centimetre.

For very low-potential machines (electroplating dynamos, battery motors, etc.), about 3-4 of the densities given in Tables IV. and V. are to be taken.

5. *Length of Active Armature Conductor.*—By means of the specific armature induction obtained from formula (1), the total length of active wire to be wound upon the pole-facing surface of any armature can be readily determined. If E denotes the total E.M.F. generated in an armature, and L_a the total length of active wire wound on it, then E divided by L_a will give the specific armature induction, V. The length of active conductor for any armature can therefore be obtained from the formula

$$L_a = \frac{E}{V}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

in which

L_a = total length of active conductor (on whole circumference opposite pole-pieces), in feet;

E = total E.M.F. to be generated in armature—*i.e.*, volt output + additional volts to be allowed for internal resistances (see Table VI.); and

V = specific induction of active armature wire, calculated by formula (1).

Introducing the value of V from (1) into (2), the formula for the length of active armature conductor becomes:

$$L_a = \frac{E}{\frac{v}{P} \times S \times \frac{\mathfrak{B}}{20{,}000}} = \frac{20{,}000 \times P \times E}{v \times S \times \mathfrak{B}} \quad (3)$$

To find the total E.M.F., E, to be generated by the armature, increase the E.M.F., *e*, wanted in the external circuit by the percentages given in Table VI. The figures in the second column of this table refer to shunt-wound dynamos, and, therefore, take into account the armature resistance only. The percentages in the third and fourth columns are to be used for series and for compound-wound dynamos respectively, and, consequently, include allowances for armature resistance as well as for series field resistance.

TABLE VI.—E.M.F. Allowed for Internal Resistances.

,, 2,000	2 ,, 1½	3 ,, 2½	2½ ,, 2

6. *Size of Armature Conductor.*—The sectional area of the armature conductor is determined by the strength of the current it has to carry. For general work, the current densities usually taken vary between 400 and 800 circular mils per ampere; in special cases, however, a conductor area may be provided at the rate of as low as 200 to 400 mils per ampere, or as high as 800 to 1,200 circular mils per ampere. The low rate refers to machines which only are to run for a short while at the time, as, for instance, motors to drive special machinery (private elevators, pumps, sewing-machines, dental drills, etc.), while the high rate is to be employed for dynamos which have a 15 or 20 hours' daily duty, as in the case for central station, power-house, and marine generators, etc.

Taking 600 circular mils per ampere as the average current density (= 475 square mils, or ·000475 square inch per ampere, or about 2,100 amperes per square inch), the sectional area of the armature conductor, in circular mils, is to be

$$\delta_a{}^2 = 600 \times \frac{C}{2P} = \frac{300 \times C}{P} \quad . \quad . \quad . \quad (4)$$

where $\delta_a{}^2$ = sectional area of armature conductor in circular mils;

δ_a = diameter of armature wire, in mils;

C = total current generated in armature in amperes; and

P = number of pairs of magnet poles.

The size of conductor may be taken from the wire-gauge tables by selecting a wire, the sectional area of one or more of which makes up, as nearly as possible, the cross-section obtained by formula (4).

In this formula, as in equation (1), half the number of parallel armature circuits is to be substituted for P, in case the former figure should differ from the latter.

The total armature current, C, in shunt and compound dynamos is the sum of the current output, *c*, and the exciting current of the shunt circuit. The latter quantity, however, generally is very small compared to the former, and in all practical cases, consequently, it will be sufficient to use the given *c* instead of the unknown C for the calculation of the conductor area. A supplementary allowance may then be made by correspondingly rounding off the figures obtained by (4), or by selecting the wires of such a gauge that the actual conductor area is somewhat in excess of the calculated amount.

7. *Diameter of Armature Core.*—If the speed of the dynamo is given, the proper conductor velocity, taken from Table III., will at once determine the diameter of the armature. Let N denote this known speed in revolutions per minute, and d'_a the mean diameter of the armature winding, in inches; then the cutting speed, in feet, per second is

$$S = \frac{d'_a \times \pi}{12} \times \frac{N}{60}. \quad . \quad . \quad . \quad . \quad (5)$$

Digitized by Google

from which follows:

$$d'_a = \frac{12 \times 60}{\pi} \times \frac{S}{N} \times 230 = \frac{S}{N} \quad . \quad . \quad (6)$$

From this mean winding armature, d'_a, then, the diameter of the armature core, d_a, is found by making allowance for the height of the armature winding. For small armatures—under 2ft. in diameter—the coefficients given in Table VII. may be used for this purpose; for larger ones it is sufficient to simply round off the result of formula (6) to the next lower round figure.

TABLE VII.—Ratio between Diameter of Body and Mean Winding Diameter for Small Armatures.

Up to 3in. diameter	$d_a = .88 \times d'_a$	—
,, 6in. ,,	$= .92 \times d'_a$	$d_a = .94 \times d'_a$
,, 12in. ,,	$= .95 \times d'_a$	$= .96 \times d'_a$
,, 18in. ,,	$= .96 \times d'_a$	$= .97 \times d'_a$
,, 24in. ,,	$= .97 \times d'_a$	$= .98 \times d'_a$

For dynamos with internal poles, the reciprocals of these coefficients are to be taken, or the result is to be rounded off to the next higher round figure respectively; and the dimension thus obtained is the internal diameter of the armature core. In the case of machines with internal as well as external poles, the mean winding diameter, d'_a, is identical with the mean diameter of the armature body.

If the speed of the dynamo is not given, the following Tables VIII., IX., and X. will be found useful. Table VIII. gives practical data for speeds, conductor velocities, and corresponding diameters of drum armatures. Table IX. contains similar information relating to high-speed ring armatures, and in Table X. the data for slow-speed ring armatures are compiled.

(To be continued.)

SOME REMARKS ON POWER DISTRIBUTION BY ELECTRICITY, WATER, AND GAS.*

BY ED. C. DE SEGUNDO.

(Concluded from page 669.)

As the thermal efficiency of steam-engines, under such working conditions as obtained in central power-producing stations, is extremely difficult to determine with any accuracy, it may be of interest to arrive at their figure by calculation of other efficiencies as nearly as they can be estimated. Probably 9lb. of coal of calorific value of 14,500 thermal units per pound is not an excessive figure to assume as the average performance of London central electric stations per kilowatt-hour, paid for by the consumer. Now, one kilowatt-hour is equal to about 3,420 thermal units. Adding 11 per cent. for loss in distribution and allowing 1·25 as the counter efficiency of the dynamos, there should appear on the crankshaft of the engine, so to speak, the equivalent of about 4,750 thermal units. But to effect this 9lb. of coal have been burnt, liberating $145·00 \times 9 = 130,500$ thermal units, so that the efficiency or non-efficiency of working of boiler and engine, together with attendant stand-by and radiation losses, are responsible for 96·2 of the heat energy of the coal consumed. Of course, the engine and boiler, as heat machines, are not to be held accountable for the whole of this loss. It is mainly due to the conditions of working. But the question that naturally suggests itself under these circumstances is, is there no other and more efficient manner of generating and distributing light and power on an intermitting demand than by steam power, generating electrical energy and distributing it by means of copper mains?

It must not be forgotten that the coal consumption is by no means the only factor to be considered. Rents, rates and taxes, maintenances and distribution expenses, depreciation, management expenses, and a host of other items have to be tacked on to the cost of coal consumed before the figure is reached from which profits can be calculated. But even on this basis the total for power delivered is strikingly smaller in the case of hydraulic power supply than in that of electric supply. In a recent paper read before the Institution of Civil Engineers by Mr. E. B. Ellington, it was stated that the total cost per 1,000 gallons delivered at 700lb. per square inch was 12s. 6d. Now, 1,000 gallons at 700lb. per square inch is equivalent to 8·34 horse-power hours, or 6·25 kilowatt-hours nearly. There is no electric supply company in London who deliver one kilowatt-hour at a less total cost than from 3·5d. to 4½d. to themselves. Thus the cost per equivalent of one kilowatt-hour is rather more than double in the case of electric supply than in the case of hydraulic supply. The question is, as to whether this economy can be ascribed wholly to the superior economy of the steam-engine in all hydraulic power stations, having regard to the fact that not only is the hydraulic load curve similar in form to the electric load curve, but the load-factors in both cases are similar. The author thinks not entirely, as a certain proportion of this economy must be due to the difference in the inevitable losses in the system of distribution, and also to the difference in capital outlay for large powers. In comparing distribution of power by high-pressure water and by electricity, due consideration must be had to the purposes to which power is to be put. For working lifts, or cranes, or presses, it is doubtful whether any simpler and better means could be provided in a city like London than water pressure. If, on the other hand, the form in which the power is delivered has to be changed before it can be applied, it is quite possible that the efficiency of transformation may be so low as to dissipate the economy attained in generation and distribution. Compare, for instance, the number of transformations necessary to enable a lift to be worked and an incandescent lamp to be lighted from a central power-house.

Lift.

Efficiency, per cent.	Hydraulic power.	Efficiency, per cent.	Electric power.
70	Boilers	70	Boilers
13	Compound condensing engines	9	Non-condensing engines
80	Pumps (including mechanical efficiency of engine)	80	Dynamos (including mechanical efficiency of engine)
99	Distributing system	88	Distributing system
		80	Motor

Of the 14,500 thermal units liberated by 1lb. of coal, 1,044 thermal units would reappear as useful work on the hydraulic system, and 478·5 thermal units on the electric system.

Electric Lighting.

70	Boilers	70	Boilers
13	Compound condensing engines	9	Non-condensing engines
80	Pumps	80	Dynamos
99	Distributing system	82	Distributing system
66	Motor		
90	Dynamos		

On the hydraulic system about 620 thermal units should reappear in useful work and on the electric system about 600 thermal units.

The foregoing assumptions are not made with regard to any

particular load-factor, but as the load-factor is found to be very similar in public electric supply stations and public hydraulic supply stations, the conclusions indicated by the figures should not be materially altered. There is, of course, nothing very new about this result, but it is sufficiently striking to have induced a Belgian engineer of considerable reputation to devote a large amount of time to the development of a system of hydraulic distribution in generating electrical energy which should enable electrical energy to be sold at considerably cheaper rates than at present. It is unnecessary to discuss M. Van Rysselbergh's scheme in detail. It is evident that the only directions in which the efficiency of a system as a whole can be increased are (1) by decreasing the number of transformations of energy, and (2) by increasing the efficiency of either or all of these. Now the number of transformations of energy is not decreased, but increased, in the hydraulic system. The efficiency of boilers and dynamos cannot be very different in both systems. The difference in the cost of the distributing system is conditioned by circumstances. There remain, then, two efficiencies to be improved on—the efficiency of the engine and the efficiency of the distributing system. The economy effected by a triple-expansion condensing engine, working as it does in an hydraulic power station at full load per stroke, over the steam-engines forming part of the "steam dynamos," now much used in electric generating stations, might well reach 50 per cent.—that is to say, where the steam-engine of the steam dynamo gives 10 per cent., the triple compound as above might yield 15 per cent. The loss in a mile of hydraulic main, say, 6·5in. diameter, when transmitting 100 h.p. at 700lb. per square inch at a velocity not exceeding 3ft. per second, would not greatly exceed 1 per cent., whereas the average loss in an electric distributing system rarely is less than 12 per cent., though doubtless this could be improved upon. Against these sources of economy must be placed the loss in the water motor, the loss in the extra transformation of motive power into electric light, and the loss in the low-tension network surrounding each distributing station. Further, hydraulic mains have to be placed at a considerably lower level than the electric conduits need be for many reasons, and it can scarcely be even a matter of doubt that the total commercial efficiency of the whole hydro-electric system—by which is meant the useful efficiency modified by all such considerations as rents, rates and taxes, maintenance, and depreciation, etc.—will compare unfavourably with the total commercial efficiency of direct electric supply. There can be no doubt, however, that power can be produced and delivered hydraulically at a smaller cost than the electrical equivalent electrically. There must be a reason for this, and the reason is not far to seek. In the hydraulic power station a more efficient engine can generally be used; then this engine can be worked more efficiently owing to the fact that although the engine may vary in speed, it works always at full load to the stroke. There can be, further, a much greater efficiency in distribution through pipes. In hydraulic-power supply the pressure is not a function of the speed of the pump (as in direct electric supply it is a function of the speed of the armature), but the pressure in the mains is maintained outside of the engine and pump, which only deliver enough water at a constant pressure, to supply the demand on the main.

At first sight it seems easy to apply this principle to electric supply by the introduction of an electric accumulator or storage battery to keep up the pressure on the mains. But unfortunately the analogy between an hydraulic and an electric accumulator is not quite complete: it breaks down in one important detail—namely, that while the hydraulic accumulator reacts in the same way upon both main and pump, the electric accumulator only acts in an analogous manner towards the main. Its effect upon the dynamo or electric pump is to drive the pump unless the pump is driven sufficiently quickly. What is wanted to complete the analogy is the analogue of the non-return valve, and this so far has not been discovered. Moreover, while pressure can be exerted by a pump, whose plunger is stationary, the pressure exerted by the electrical pump or dynamo is a function of the speed of rotation of the armature. Thus, in order to supply a small demand, the steam-engine of an electric generating station has to work at about 90 per cent. of the speed required to supply the full demand. There is no reason why an electrical generating station should not be able, provided the demand is sufficiently large and varied, to so apportion its generating units as to keep each unit in work loaded to 90 per cent. of its full load, in which case the only losses in the station would be 10 per cent. stand-by in boilers, radiation, etc. In the Berlin central station, where, owing to continental habits of life, the demand is more favourably distributed over the 24 hours, such a condition is very nearly approached.

Efficiency of Gas-engines.

Now let us briefly consider how power produced by gas-engines can meet the needs for electric light for a large town provided with a complete network of gas-mains. In this case (which is practically the case of every large town in the civilised world) the electric light comes as competitor against the method of illumination which has practically only just established a firm reputation for reliability, economy, efficiency, etc. There is no doubt that the conveniences of gas for lighting and heating are apt to be overlooked because of our familiarity with them. Had we experienced the inconveniences of oil and candle lighting, I feel sure the electric light would not have made so much progress as it has done Further, the gas business is in the hands of a powerful body, powerful alike in experience and in resource. Experience of practical working in London and other large towns show that in certain districts and under certain conditions there is a sufficient demand for the electric light to make it worth while to work independently of the gas company altogether. But consider the very vast majority of country towns already supplied with gas, where it is obvious that an independent electric light company would eke out a very miserable existence, and that probably for only a short time, it would certainly seem reasonable that a combination of electric light and gas interests would solve the problem of electric supply to the inhabitants; and if this is so, then the principle ought to apply *à fortiori* to large towns. At present these interests conflict, and it is universally experienced that someone has to pay for this conflict. Let us try and examine this a little more closely. If electric light and gas interests harmonise, the first advantage that suggests itself is the ready-made central station—namely, the gasworks. It is then necessary to establish distributing stations at suitable points in the town. Each distributing station would consist of gas engines and dynamos and regulating apparatus. Each distributing station would supply its own network of mains for the needs of its own neighbourhood. These networks would have to be connected by a trunk main so that any one station could be relieved by any other in case of emergency, and during the period of light load. The details of the plant of each station and the number of stations would be dictated by local conditions, so that it is impossible to do more than state the broad principles. As there would be no boilers, no chimney-stack would be required. Probably in nine cases out of ten the basement of some house could be adapted to accommodate the necessary plant, hence a great saving would be effected in special buildings. Further, the labour required would be diminished. The cost of superintendence would probably remain the same, but might be increased. Now, as to the cost per unit delivered. There is fortunately not much difficulty in determining this, as many examples of the generation of electrical energy by gas power now exist. The author has selected the results of the weekly records of a plant at Bradford supplying 300 lamps. The total cost per kilowatt-hour delivered is almost exactly 2d., with town gas at 3s. 3d. per 1,000. But to adapt this to a distributing station 5 per cent. should be added for loss in mains, and 0·3d. per kilowatt-hour for depreciation in plant and buildings. This would bring the cost to 2·4d. Adding the very liberal allowance of 0·6d. per kilowatt-hour for management expenses, the total cost would amount to 3d. per kilowatt-hour delivered. This is a lower figure than that usually realised in practice by any purely electric supply company working under the conditions above assumed, and no doubt this aspect of public electric supply has for some reason or other not receive the attention it deserves. In order that the two systems (direct use of gas and gaso-electric) be commercially equivalent, the cost of maintenance of the plant, the interest and depreciation, and management expenses must be compensated for by the economy in gas consumed.

Now it is frequently thought that nothing can be more economical than the system of sending the gas direct to the burner. But this is far from being true. The miserably low efficiency of the gas burners is rarely appreciated. According to Prof. Tyndall, the efficiency of the gas burner is 0·317 per cent. Taking the calorific value of London gas at 620 thermal units per cubic foot, only the equivalent of 10 thermal units reappear as light out of a possible 3,100 thermal units in a 5ft. burner. When gas is utilised to produce motive power, its efficiency and that of the incandescent lamp is so superior that a very different result is obtained. The efficiency of a 16 per cent. incandescent lamp being about 6 per cent., and assuming a mechanical efficiency of 80 per cent. for the gas-engines and 85 per cent. for the dynamos, including loss in transmission, it is found that about 25 thermal units would reappear as light out of a possible 3,100. So that in spite of the threefold transformation of energy introduced, the final result is increased 2·5 times. This ratio would of course be still further increased in the case of arc lamps. The value of these ratios, taking minimum values in the cases of electric generation by gas-engine power, are as follows:

Character of burner.		Percentage increase of candle-power obtainable by using a gas-engine to drive a dynamo supplying electric lamps, as compared with that obtained by burning the gas district.
Gas.	Electricity.	
		Per cent.
A good ordinary 5ft. gas burner, such as a Bengel burner.	An incandescent electric lamp, using 4 watts, per candle and giving 16%.	78
A Wenham lamp.	An arc electric lamp of same power as Wenham gas lamp.	227

The reason of this is that the chemical combustion of coal gas with oxygen yields a flame in which the undulatory vibrations of a sufficient frequency to become luminous are extremely few compared with the heat waves, whereas in a gas-engine it is these heat waves that are transformed into mechanical energy. The chief points of a gaso-electric system of distribution may be summed up as follows:

1. The generating station already exists and may be considered as an eccentric power-house.

2. The existing gas-mains are available; hence there is no question of a separate main network being laid as in the case of hydro—or æro—electric supply.

Digitized by Google

3. The useful efficiency of gas is out of all proportion greater when utilised as a motive power than when burnt direct in burners, and this in spite of the extra transformations of energy introduced.

4. It is more than probable that under a system such as has been discussed above, the cost of maintenance, superintendence, and management expenses will be less than under conditions of independent electric supply.

5. By paving the way for the substitution of electric for gas lighting without conflict of existing interests, an incalculable benefit is conferred on the community.

Of course, the hydro-electric system may be treated from the same point of view if once hydraulic supply mains exist; but the present efficiency and character of high-pressure water motors do not suggest the possibility of any very great economy being effected. It must not be forgotten that Van Rysselbergh's claim to economy is based upon a motor efficiency of 80 per cent., which, though not unattainable, is very high and could not be relied on as an average result in practice; but for large private installations the energy supplied by the hydraulic power company could with advantage be utilised.

ELECTRIC LIGHTING AND PUMPING PLANT FOR MINING PURPOSES.

An electric lighting and pumping plant has recently been completed at Milnwood Colliery, Bellshill, N.B., for the Coltness Iron Company. The installation has been carried out by Messrs. Ernest Scott and Mountain, Limited, of Newcastle-on-Tyne, and it is one of the most complete laid down. The installation consists of the lighting plant for the colliery and for the miners' cottages, and pumping plant for pumping the water from the river.

The colliery lighting plant consists of an improved "Tyne" compound-wound dynamo, constructed so that it can either be used for the colliery lighting or for the lighting of the miners' cottages. To enable the machine to do this work the field magnets are wound in a special manner, so that when running the lights at the colliery the machine gives a constant E.M.F.; but by switching in an additional coil on the magnet, the machine can be used for lighting the lamps at the cottages, and gives a constant pressure at the cottages, whatever number of lamps there may be on the circuit. The current from the dynamo is taken to a main switchboard, which is fitted with two double-pole main switches, and is there divided into the two main circuits—*i.e.*, one circuit for the surface lighting and one for the underground lighting. The surface is lighted by four 2,000-c.p. arc lamps, working two in series over 100 volts, and suspended from poles fitted with wrought-iron head gears, with raising and lowering gears, consisting of a winch and the necessary length of stranded steel suspending rope. In addition to the arc lights there are about 100 incandescent lamps distributed about the pit-head, etc. These are all attached to substantial fittings, and a large number of branch circuits has been fitted, so that the lights can be switched on or off as required. About 30 incandescent lamps are used for the lighting of the underground; these are all attached to ceiling fittings with wire guards, and the current to these lamps is taken down the shaft by armoured cables.

The installation for the miners' cottages, of which there are 34, consists of a dynamo which is an exact counterpart of the machine used for feeding the lamps at the colliery. The current from the machine is taken to a main switchboard fitted with a double-pole main switch, and is then carried overhead by copper conductors suspended upon oil insulators. The total length of conductors, out and home, is about 1,500 yards. The cottages are lighted by 102 16-c.p. lamps—*i.e.* three lamps to each—the lamps in the sitting-rooms are fitted with raising and lowering gear, and switches are fitted to each lamp.

The pumping plant comprises a "Tyne" shunt-wound dynamo, constructed to give an output of 350 volts and 34 amperes. The current is taken to a double-pole main switch, and is then conveyed by overhead cable, the total length being 2,600 yards, to the pumps, which are placed in a pump-house by the river. The pumps are of the company's improved three-throw ram type, the rams being 6in. diameter by 9in. stroke, and the pumps are capable of delivering 120 gallons of water per minute when running at a speed of 40 strokes per minute. The three pump bodies are separate castings, each similar in design and interchangeable; each pump is fitted with a gland bushed with gunmetal, and the stuffing-boxes are also bushed with gunmetal. Suction and delivery valve-boxes are all separate castings fitted with gunmetal valves and seats, the valves being of extra large diameter to ensure an easy passage for the water, and each valve is fitted with an adjusting gear, so that the lift of the valve can be regulated The connecting pipes, both on the delivery and suction side, are also separate castings, and an air-vessel is fitted on the delivery branch. The object in constructing the pumps in this manner is to prevent any possibility of a total breakdown. In the cheaper type of pump it is customary to cast valve-boxes and pump body in one casting, the result being, if there is frost and the castings should be cracked, the whole pump is destroyed, whereas in the design of pump under consideration, in the event of any particular part being broken, the pumps are still capable of working, even with only one or two rams. The rams are of gunmetal, and are attached to slipper guides working in guide plates forming an oil-bath, and thus providing continuous lubrication. The connecting-rods, crankshaft and countershaft are of steel, all fitted with extra long bearings to avoid wear and tear. The power from the motor is transmitted to the pumps through a pair of spur wheels, a pulley being mounted on the outer end of the countershaft to receive the driving belt from the motor. The electric motor is of Messrs. Scott and Mountain's improved mining type, and is capable of giving 13 effective horse-power when running at 700 revolutions. A starting switch is provided, so that the motor can be stopped or started slowly, and all shock taken off the pumps. This plant has now been at work some time, and has given very satisfactory results.

ELECTRIC LIGHTING OF COLCHESTER.

REPORT BY MR. MASSEY.

At the monthly meeting of the Town Council last week, the Lighting Committee submitted the following report received from Mr. W. H Massey, as to (1) the practicability of supplying electric light for public and private purposes without incurring loss or increasing the rates, and (2) the best course to be adopted for carrying out the provisions of the Colchester Electric Lighting Order:

"I have carefully considered the various matters about which you did me the honour to ask my advice, and, having regard to certain transactions in the past, when I acted for some members of your Corporation, my recent investigation was purposely made more full than was necessary, perhaps, but it is not my intention to trouble you with a long report, and when we come to estimates of cost, I shall (in the best interests of your Council) give no more details than I can help My opinion eight years ago was that electric lighting in your borough could not be carried on at a profit by a company, and I am of that opinion now. In 1885-6 it was confidently expected by several firms, whose schemes were submitted to me, that an annual revenue of from 30s. to 40s. per 50-60 watt lamp would be obtained, and I had to take into account the fact that many large customers were then prepared to enter into contracts for the supply of current upon those terms. The cost of production has gone down very much since then, but we know from actual experience nowadays that one cannot depend upon more than 10s. per year per 30-40 watt lamp (fixed) in any provincial town, so that the prospects of earning dividends is almost exactly what it was.

"There is more bright weather and sunshine in Colchester than in any town I know of in England, and the revenue per lamp will be less there than in such a place as Southampton, which is in the hands of a company, or in Hull, where the Corporation electric light works are said to be already paying their way. I think Northampton may be taken as a guide in what should or should not be done at Colchester; but in order that the committee may have some means of judging for themselves, I enclose an analysis of the Board of Trade returns, which is printed each week in one of the technical journals, and I have marked certain portions of it so that your attention may be directed to figures which are not the less valuable for not being embodied as original matter in a report. You asked me to put the facts plainly before you, and I know that you will not be led away by anything you may have heard or read as to the cheapness of electricity produced under conditions seldom, if ever, to be met with in practice. If my views had not, in the main, been correct, you would ere this have receive applications for a transference to others of the valuable powers granted to you under a provisional order last year. But although a company might stand very little chance of being financially successful in Colchester, it does not follow that your Corporation would fail also. You are in a position to borrow money so cheaply that 5½ per cent. is sufficient for interest on and the repayment of a loan within the period (25 years) usually fixed by the Local Government Board, and nothing would have to be paid for promotion, or for such other purposes as are essential when a company tries to raise money. The salaries of a secretary and a clerical staff can be saved to some extent by judicious arrangement on the part of your town clerk, and the superintendence charges would be low if the electric light department could be placed under the borough engineer. Establishment and working expenses might be reduced to a minimum if only the various works of a corporation could be so combined that one staff might assist in running two or more things hitherto kept entirely distinct. This bears directly upon the question of sites, to which I shall allude presently, but I would venture to dwell for one moment longer upon a point generally lost sight of—viz., that in well-regulated institutions and on economically managed estates, some of which may well be compared to small towns, the same staff will attend to heating, ventilating, pumping, and waterworks, electric lighting, fire service, gasmaking, laundry work, sewerage, etc, and not only are the boilers and much of the machinery brought into the same buildings, in order that the running expenses shall be small, but the object of an engineer called in to prepare plans for, or to reorganise a comprehensive scheme of that kind, would naturally be to obtain efficient duplication of apparatus in a way that leads to a saving in first cost as well as in maintenance. I am aware of the difficulties of carrying out all corporation work on similar lines; but I submit to your committee, for their most serious consideration, the desirability of trying to run their electric lighting works (whenever they may be established) in conjunction with something else, so as to reduce expenditure of every kind, and to make the most of an advantage which a corporation undoubtedly possesses over any private or public firm endeavouring to carry on similar work.

Digitized by Google

"I have, in company with the chairman of your committee, Mr. E. Thompson Smith (who has taken a good deal of trouble in this matter on various occasions when I have visited Colchester), inspected five sites—the waterworks, the water-tower, the milk factory, the Middle Mill, and vacant ground near the Corporation yards, and Mr. Goodyear, the borough engineer, has furnished plans and particulars which have been of great use to me.

"At the water-tower the cartage of coal would be dear, and condensing water in large quantities is not available. At the milk factory there is no machinery which I could recommend you to adopt for a modern electric light station, and it would cost nearly as much to strip and adapt the existing buildings as to erect new and more suitable works. At the Middle Mill there is water power sufficient for light day loads and all night work, but this power would have to be supplemented by steam for heavier loads, and unless the site could be bought very cheaply, the cost of carting coal to it, and the impossibility of combining any other scheme with that of electric lighting, to say nothing of the necessity for protecting the electrical machinery from the effects of floods, would have to set against the value of the water power available, and I think on the whole that you had better go elsewhere.

"At the waterworks site a combined scheme might still be arranged, so that steam power could during the day be supplied from a new set of boilers common to both undertakings, and a saving would thus be effected in the wages of the attendants. Coal is used there now, so I suppose the cost of hauling is not so prohibitive; but I fear that complications might arise as to the condensing water, and failing an agreement between the Waterworks and Lighting Committees, a combined scheme would fall through.

"A question as to the disposal of your town refuse having been raised, I paid a special visit with your chairman to the piece of land between the milk factory and the Corporation yard, where, I am informed by your borough engineer, water may be had in abundance for condensing purposes; and even if it should be necessary to lay a separate pipe to lead away the waste water so as to keep it out of your sewers, to save pumping at the sewerage works, I believe that upon this vacant ground you would be able to arrange for electric light works side by side with apparatus for burning refuse in a manner that would prove advantageous to the ratepayers. St. Botolph's Station is so near that coal could be delivered on this site as cheaply as at the milk factory. The price of the land is moderate, and some of the adjoining cottage property might be bought in to give additional space and facilities for dealing with the urban sanitary requirements.

"On receiving your committee's further instructions I shall be glad to prepare plans, in conjunction with Mr. Goodyear, which would, I hope, recommend themselves for your acceptance if it is decided to proceed with the electric lighting of Colchester.

"To provide only for the lighting of North-hill, Head-street, and High-street, as far as St. Nicholas's Church, by arc lamps, and for the supply of current to about 3,000 40-watt incandescent lamps out of a total of 4,000 or 5,000 fixed in the houses and shops in these streets, a total expenditure of nearly £13,000 would have to be incurred by the Corporation, and I am quite sure in my own mind that if the scheme is limited to this area (the compulsory area of the provisional order) there will be a difficulty in making the electric light pay its way, even in the hands of the Corporation; but if you are willing to take in portions of Crouch-street and St. John's street, of St. Botolph-street and Queen-street, so as to embrace an area in which it is reasonable to suppose 6,000 or 7,000 lamps would be fixed in houses and shops, I estimate that the total expenditure would be about £18,000. To this it would be wise to add £2,000 as working capital, so that a loan of, say, £20,000 would be required.

"The amount to be set aside for interest and repayment would be £1,100 per year, and the scheme would become self-supporting as soon as a gross yearly rental of £2,000 (including £300 for street lighting) could be obtained.

"*Systems.*—It appears to me improbable that there will ever be any great extensions to portions of the borough far distant from the compulsory area, and the system I should recommend, therefore, is the low-tension three-wire system (or some modification of it), if the site near the Corporation yard is chosen; but if your committee are of opinion that provision should be made for future extensions to a distance, my scheme would have to be modified somewhat, without, however, the question of total expenditure being very much affected. If either the waterworks site or the Middle Mill site be selected you would have to adopt the high-tension alternating-current system, because the stations would then be outside the area of supply; but in these cases also the figures I have given would hold good, the only difference being that the running expenses would be a trifle higher than those in the low-tension scheme for which I have worked out the details."

The committee proposed, in accordance with a suggestion made by Mr. Massey to the chairman, and with a view to ascertaining the probable number of lamps to be supplied with light, to send a circular to the occupiers of premises situated within the large area specified in the report, giving information in regard to the probable cost of the light, and enquiring whether such occupiers are prepared to avail themselves of the supply, and if so, to what extent. The committee hoped that they may be in position to make a recommendation to the Council at its next meeting.

Mr. Thompson Smith moved the adoption of the report, which he said was a very able one, and would require a good deal of consideration. The committee, as stated in the report, proposed to take certain steps with a view to ascertaining the desires and wishes of the inhabitants of those parts of the borough which were proposed to be lighted, and till those wishes were ascertained it would be far better the matter should be left in the hands of the committee.

The adoption of the report was agreed to.

COMPANIES' MEETINGS.

SOUTH STAFFORDSHIRE TRAMWAYS.

An extraordinary general meeting of this Company was held on Tuesday at the Cannon-street Hotel, E.C., for the purpose of electing directors and auditors.

Mr. W. S. Schuster was voted to the chair, and said that the meeting was purely formal. The petition presented for the winding up of the Company, with a view to its reconstruction under the Court, was adjourned by Mr. Justice Vaughan Williams to give the shareholders an opportunity of expressing their views upon it. Since then the present directors had signified their intention to retire, in order that a new Board might be constituted; and, under these circumstances, the petition would not be proceeded with. The new Board, he said, was entirely unfettered so far as regarded the enforcement of claims against the late directors or other persons connected with the Company, and its policy would be to come, if possible, to some all-round compromise and arrangement by which the line could be taken out of the hands of the receivers and placed upon a permanent basis. If satisfactory arrangements could not be brought about, the new Board would recommend the shareholders to litigate or wind up. Investigations made for the purpose of litigation had thrown a great deal of light upon the history of the Company, and it was not proposed, having regard to possible future litigation, to introduce the matter into the meeting, although the fullest information would be given to any shareholder who liked to apply for it privately.

In reply to a shareholder, **Mr. Elliott** said it was probably within the knowledge of the meeting that some time ago a petition was presented for winding up, alleging various acts on the part of the directors and others connected with the Company as grounds for so doing; but the judge, after reading the affidavits, said his opinion was that the matters stated in them were not grounds upon which he could order the winding up.

Mr. Munns said it was hoped that when the new Board was appointed some settlement would be come to with the debenture-holders, which would take the line out of their hands, and also with the Electric Construction Corporation, by means of which the charges which the Company was liable to pay under the contract would be modified.

Resolutions were then adopted accepting the resignations of the directors, electing Messrs. W. S. Schuster, S. R. Blundstone, and A. Dawson as a new Board, and appointing Messrs. Spain and Hardcastle as auditors.

SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

The shareholders in the Swan United Electric Light Company, Limited, unanimously agreed yesterday (Thursday) afternoon to a resolution that the Company should be voluntarily wound up, and Mr. H. C. Gover, of 100, Victoria-street, Westminster, was appointed liquidator. Mr. Gover was authorised to carry into effect upon the terms of a provisional agreement a sale of the Company's undertaking to the Edison and Swan United Electric Light Company. Mr. J. Staats Forbes, who presided at the meeting, made one of his characteristic speeches. He gave a historical account of the proceedings that had led to the decision that it was far better to amalgamate the two companies than to continue to work separately. The Swan Company held 60 per cent. of the shares in the Edison Company, and the residuum of the former's business was to be sold to the latter for £100,000 worth of debenture stock, to be distributed among the shareholders of the Swan Company. The fully-paid shares would receive three fully-paid Edison and Swan shares for every five fully-paid shares in the Swan Company, and about £1. 4s. in debenture stock in respect of each fully-paid share in the Swan Company. Partly-paid shares would receive about three partly-paid shares in the Edison Company for five partly-paid shares in the Swan Company and about 19s. 3d. in debenture stock in respect of each share.

ELECTRO-CHEMICAL COMPANY.

The statutory general meeting of the Electro-Chemical Company, Limited, was held on Tuesday at the Cannon-street Hotel, E.C.

Colonel Holland, C.B., presided, and stated that 16,745 preference shares, representing £83,725, together with 14,000 ordinary shares, representing £70,000, had been allotted, making in the aggregate a total capital of £153,725. Further applications from preference shareholders were still coming in, and were being considered as they were received. The Board had ample capital subscribed for all the requirements of the Company. The purchase of the Company's patents was completed, and they were in course of being transferred to the Company. Up to the present time, however, no money had been paid to the vendor, he agreeing to take £25,000 out of the £30,000 to be paid to him in shares. It was proposed at first to lay down machinery to manufacture annually 5,000 tons of caustic soda and bleach. Negotiations were in progress for the sale of some of the foreign patents. They had every reason to believe that by the new process they would be able to manufacture caustic soda at 50 per cent. less than

Digitized by Google

the market price. The patents had been carefully secured to the Company.

On the motion of **Mr. Marcus**, Colonel Holland's election as a director of the Company was confirmed.

COMPANIES' REPORTS.

ELECTRIC AND GENERAL INVESTMENT COMPANY, LIMITED.

Directors: George Herring, Esq., chairman; the Right Hon. Lord Cloncurry; J. R. Braithwaite, jun., Esq.; B. H. Van Tromp, Esq.; Emile Garcke, Esq., managing director.

Report of the directors to be submitted to the fifth ordinary general meeting of the shareholders to be held at Winchester House, Old Broad-street, E.C. (Room No. 47), on Tuesday, June 26, 1894, at 3 p.m.

The directors beg to submit the balance-sheet and profit and loss account for the year ended May 31, 1894. The profit and loss account shows a gross profit on the transactions of the year (including the balance of £65. 16s. 5d. brought forward from last year) of £10,735. 6s. 8d., and after deducting all standing charges, and the interim dividend already paid on the ordinary shares, there remains a net balance available for distribution of £7,369 10s. 4d. The directors now recommend the payment of a further dividend upon the capital paid up on the ordinary shares at the rate of 40 per cent. per annum for the past six months, and a dividend on the founders' shares of £30 per share for the year. This will leave a balance of £369. 10s. 4d., which the directors recommend should be added in equal moieties to the ordinary and founders' reserve funds. The directors who retire this year are Mr. G. Herring and Mr. B. H. Van Tromp, but being duly eligible, offer themselves for re-election. The auditors, Messrs. Rait and Kearton, also retire, but offer themselves for re-election. It is proposed to make the dividends payable on June 27, 1894.

Dr. BALANCE-SHEET, MAY 31, 1894.	£	s.	d.
Capital authorised — £200,000 in 39,900 ordinary shares of £5 each, and 100 founders' shares of £5 each.			
Capital subscribed—20,000 ordinary shares, 100 founders' shares.			
Capital called up—£1 per share on 20,000 ordinary	20,000	0	0
£5 per share on 100 founders ...	500	0	0
	£20,500	0	0
Reserve fund—founders' shares	10,133	5	4
Reserve fund—ordinary shares	10,133	5	5
Provision for contingencies	8,000	0	0
Loan account	2,500	0	0
Sundry creditors	3,680	2	11
Unclaimed dividends	5	1	8
Balance of profit and loss account	7,369	10	4
	£62,321	5	8

Note.—There is a contingent liability amounting to £35,431. 5s. in respect of calls that may become due on securities held by the Company.

Cr.	£	s.	d.
Investments at cost	50,552	10	3
Sundry debtors	918	3	6
Cash in hand and on current account at bankers £712 4 11			
Ditto—dividend account 5 1 8			
	717	6	7
Founders' reserve fund, amount invested	10,133	5	4
	£62,321	5	8

PROFIT AND LOSS ACCOUNT YEAR ENDED MAY 31, 1894.

Dr.	£	s.	d.
General charges, including directors' fees, and additional remuneration as per articles of association, salary managing director, general expenses, legal charges, advertising, printing, and auditors' fee, etc.	2,365	16	4
Interim dividend paid December 1, 1893, at the rate of 10 per cent. per annum for the six months	1,000	0	0
Net profit available for division	7,369	10	4
	£10,735	6	8

Cr.	£	s.	d.

	£10,735	6	8

Baird, Thompson, and Co., Limited.—This Company has been registered with a capital of £60,000, in £5 shares, to acquire the business of Baird, Thompson, and Co., and to carry on the founding and working of iron, brass, and other metals, ventilation, heating, draining, and sanitation of buildings and streets, towns, shops, etc., pneumatic and hydraulic engineering, the destruction of town refuse, electricity and electrical engineering.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,576.

Maidenhead.—Electrical communication has been established with the dwellings of the firemen.

Poole.—The Board of Guardians have accepted the tender of Messrs. Bayley and Sons for the supply of electric bells.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 10th inst. amounted to £843.

Commercial Cable Company.—A quarterly dividend at the rate of 7 per cent. per annum has been declared, payable July 2.

Tenders for St. Pancras.—The tenders for the erection of generating station buildings for the St. Pancras Vestry are to be sent in by Monday.

Fleetwood.—October 20 is the date upon which the Board of Trade have fixed as the limit of time under the Fleetwood Electric Lighting Order, 1890.

Bristol.—Messrs. Henry Naish and Son have rebuilt their bacon factory in West-street, and the new buildings have been fitted throughout with the electric light by Messrs. Scull.

Cruto Incandescent Lamp Agency, Limited.—This Company has been registered with a capital of £5,000, in £1 shares, to carry on business as electricians, mechanical engineers, etc.

Oxford.—On the occasion of Lord Salisbury delivering the opening address at the meeting of the British Association, the Sheldonian Theatre will be specially lighted by electricity.

Baslow.—Mr. E. Scott Anderson, consulting engineer of Sheffield, has informed the Baslow Local Board that the water power available is sufficient for the supply of electric light to the town.

Salisbury.—An electric charging station has been opened at 100, Bedwin-street by Mr. E. R. Dall, A.I.E.E., for charging all kinds of portable accumulators for police, cycle, carriage, and other lamps.

Eccles.—The Town Council have authorised the Electric Lighting Committee to visit Whitehaven for the purpose of obtaining information on the subject of the lighting of the streets by electricity.

Launcestown.—The Western Electrical Company have written to the Launcestown Town Council offering to purchase the existing waterworks for electric lighting purposes, but the Council have taken no action in the matter.

Newgas and Co. v. the Gulcher (New) Electric Light Company.—Mr. Justice North has made an order in this debenture-holders' action for the appointment of a receiver of the property of the defendant company.

Post Office Telephones.—The new Post Office telephone, devised under instructions given by the chief engineer to the Post Office, is now being manufactured by the Consolidated Telephone Construction and Maintenance Company, Limited.

Chiswick.—The Chiswick Local Board have referred to a committee the plans sent in by Messrs. Bourne and Grant, the holders of the provisional order for lighting the district, of the proposed buildings and engines at the generating station.

Electrophone, Limited.—This Company has been registered with a capital of £20,000, in £5 shares, to acquire the undertaking of the Electrophone Syndicate, and to carry on the business of telephonic and electrical apparatus manufacturers.

Public School Lighting.—Messrs. Allpress and Co., of 55, Victoria-street, Westminster, are now fitting up the electric light and machinery required for generating the current at the Tonbridge Schools, belong to the Skinners' Company, at Tonbridge, Kent.

St. Austell.—The Local Board have received a letter from Messrs. Veale and Co, Limited, respecting the electric lamp on the fountain. Mr. Hicks has given notice that at the next meeting he will move that the resolution passed on the subject on May 8 be rescinded.

Tenders for Cheltenham.—Tenders are invited for the supply and delivery of electric lighting cables for this borough. Particulars are given in our advertisement columns. The tenders for the erection of a central station for the Town Council are to reach the town clerk not later than Tuesday next.

Maidstone.—At the last meeting of the Local Board, Alderman Long remarked that the Board's electric lighting order expired in a few weeks. He would like to know what the committee were doing. In reply, the Deputy Town Clerk stated that they were waiting for a reply from a company in London.

Dover.—The surveyor reported to the Town Council last week that he had received notice from the electric light company that all the boxes were in on the sea-front except one transformer-box. They had also given notice that they intended to lay the mains down from the Market-square to the Town Hall.

City and South London Railway.—The receipts of the Company for the week ended June 10 were £911, against £759 for the same period last year, or an increase of £152. The total receipts for the first half-year of 1894 show an increase of £671 compared with those for the corresponding period of 1893.

Electric Crane and Generating Plant.—The tender of Messrs. J. G. Statter and Co., 68, Victoria-street, S.W., has been accepted for the electric crane and generating plant at the works of Messrs.

Digitized by Google

C. H. Glover and Co., Hatcham Sawmills, S.E, to whom Mr. E. R. Dolby, of Westminster, is acting as consulting electrician.

Tenders for Gas-Engines.—The Council of the borough of Reigate invite tenders for the supply and erection of two Atkinson Cycle gas-engines, with heavy flywheels, starting valves, water-tanks, piping, connections, and foundation bolts. Tenders are to be delivered at the office, 84, Station-road, Redhill, Surrey, by 25th inst.

Belfast.—At a meeting of the Electric Lighting Committee a few days ago, the engineer reported the progress made in the works since the last meeting. A letter was read from Prof. Kennedy intimating his intention to visit Belfast to go over the works with the resident engineer, and to consult with the resident committee.

Bournemouth.—The Town Council have passed the following plans sent in by the electric supply company: new main from Queen's-road to Branksome Wood-road; transformer pits in Commercial-road and the Triangle; altered service to transformer pit at Lansdowne; and new cast-iron cable duct from Poole-hill to the Square.

Nottingham.—A public meeting has been held for the purpose of considering the desirability of promoting tramways to serve the Woodborough-road and Mapperley Plain districts. A committee was appointed to ascertain whether the haulage would best be by cable or by electricity, the probable cost and income, and all other necessary particulars.

Tenders for Aberdeen.—As stated in our last issue, the President and Governors of Robert Gordon's College in Aberdeen invite, by the 19th inst., tenders for the supply of materials, and the wiring of Robert Gordon's College; the supply of two 1-h.p. electric motors; and the supply of materials and the wiring of Gray's School of Arts.

Shrewsbury.—The Board of Trade Provisional Order Bill, empowering the Shropshire Electric Light and Power Company to provide electricity and supply current through the mains to consumers by meter in Shrewsbury, has passed the Examiner on Standing Orders in the House of Lords, and has been ordered to be reported for second reading.

Tenders for Railway Stores.—The Highland Railway Company are asking for tenders for the supply of telegraph instruments and fittings and telegraph construction material. Forms of tender may be obtained on application to Mr. J. G. Bulmer, storekeeper, Inverness. Tenders must be lodged with Mr. And. Dougall, secretary, Inverness, by 23rd inst.

Acton.—The Local Board have received a letter from Mr. Medhurst acknowledging the clerk's intimation that the Board desired to terminate the negotiations with him for the taking over of the Board's electric lighting order. As no replies have been received to the advertisement for purchasers of the provisional order, the Board have resolved to advertise again.

Nelson.—At a meeting of the Town Council the Gas Committee resolved that, subject to provision in any agreement, all consumers of electricity should be charged per meter. Answering Councillor Spencer, Alderman Wilkinson said that unless there was an agreement to the contrary previously made, all consumers of the electric light would be put on meter whether they were willing or not.

Plymouth.—In the House of Lords on Tuesday the Bill confirming the provisional order of the Board of Trade authorising electric lighting at Plymouth was ordered to be read a third time. In connection with a Bill conferring powers on Veale and Co. for the electric lighting of St. Austell and district, the examiner has been satisfied that the Standing Orders have been complied with.

St. Luke's.—The St. Luke's Vestry have decided, in consequence of the County of London and Provincial Electric Lighting Company having agreed not to offer any opposition to the St. Luke's Vestry, should they at some future time determine to apply for a provisional order to supply electric light in the parish, to inform the Board of Trade that they see no objection to the company carrying out the work of lighting the parish.

Strand.—The Strand District Board of Works have adopted a special report of the Works Committee on a memorial from the Charing Cross and Strand Electricity Supply Corporation, which proposed to supply electricity in the parish of St. Paul's, Covent Garden, at £26 per arc lamp of 2,000 c.p. The committee expressed the opinion that if competitive powers were granted to a second company, they should apply to the district as a whole and not to one parish.

Accepted Tenders.—The tender of Messrs. W. Gradwell and Co., of Barrow-in-Furness, has been accepted for the erection of the electric light station at Newport (Mon.), and that of Mr. C. Haywood, junior, has been accepted for the erection of a generating station and depôt at Foleshill, for the Coventry and District Tramways. Messrs. Vaughan and Brown have received the contract for the wiring of The King's Arms, Bishopsgate-street Without, E.C.

Newport (Mon.).—The committee of the Newport Corporation having charge of the electric lighting project have decided that the charge to consumers shall be as follows: under 1,000 units per quarter, 6d. per unit; above 1,000 and under 2,000 units per quarter, 5½d. per unit; above 2,000 units, 5d. per unit. It has been decided that all corporate buildings, such as the Town Hall, free libraries, markets, baths, slaughter-houses, etc., shall be lighted by electricity.

Llandudno.—Mr. William Kingsland, A.I.E.E., electrical engineer, has recently removed from Clarence-buildings to new premises at 139, Mostyn-street. Mr. Kingsland and Mr. R. Bellis are pushing on with their scheme for giving Llandudno the benefit of a central electric supply station, and thus bringing it up to date with other first-class watering places. A strong directorate has been formed, and the Llandudno Electric Supply Company, Limited, will be registered in a few days.

West's Gas Improvement Company, Limited.—This Company has been registered with a capital of £100,000 in £20 shares. The object is to acquire the business of manufacturers of machinery and apparatus connected with the manufacture, purification, storage, distribution, and employment of gas, as hitherto carried on by the West's Gas Improvement Company, Limited, at the Albion Ironworks, Miles Platting, Manchester, and to carry on business as gas, electrical, and mechanical engineers.

Woodhouse and Rawson, United.—In the matter of Woodhouse and Rawson United, Limited, the public examination of Lord Aberdare, Sir R. W. Rawson, Sir John Stokes, Samuel Pope, Q.C., F. L. Rawson, W. T. Stutchbury, Albert Hoster, T. H. Lambert, C. L. Baker, A. L. Foley, J. H. Owen, Malcolm Dundas, — Mumford, Philip Rawson, and F. W. Pixley has been fixed for the 18th inst., and two following days, before the Registrar, at Bankruptcy-buildings, Carey-street, Lincoln's-inn, W.C.

Brighouse.—Messrs. Sharpe, Parker, Pritchards, and Barham, Westminster, solicitors and parliamentary agents, have been appointed by the Town Council to act for them in the promotion of the Bill in Parliament during the ensuing session for the purchase of the undertaking of the Rastrick Gas Company, electric lighting, and other municipal matters. A good many business houses in this district are now supplied with the electric light by Mr. A. B. Brook, who has put down a plant in Hall-street.

Aberdeen.—The question of the lighting of the new police buildings by electricity has been discussed at a meeting of the Watching and Lighting Committee of the Town Council. An estimate was submitted, which showed that the cost of carrying out the scheme would be £250, but it was explained that £100 would be saved on gas fittings, so that the net extra cost over gas would be £150. The proposal met with general acceptance, but it was agreed to defer further consideration till next meeting.

Ayr.—At a meeting of the Municipality a letter was read from the Ayr Harbour Trustees desiring to know what the Commissioners would charge for supplying eight arc lamps 3,000 c.p. for the north side of the river and dock, and four arc lamps with similar power for the south side of the harbour. The application had been forwarded to Mr. Hammond, who advised that the Harbour Trustees should be supplied with electricity at the rate of 4d. per unit, they providing the lamps and other plant required in connection with the installation.

Ship-Lighting.—Messrs. Charles Connell and Co., Whiteinch, Glasgow, have launched from Scotstown Shipbuilding Yard a large and fully-equipped steel screw-steamer for Messrs. Greenshields, Cowie, and Co.'s Knight Line, of Liverpool. For expeditious working of cargo, she has seven hatches and seven of Messrs. Clarke, Chapman, and Co.'s steam winches, and when it may be necessary to work at night she is supplied with a cluster of electric lamps to illuminate the decks. The vessel has a complete installation of electric light, carried out by Messrs. J. H. Holmes and Co.

Lighting of the City.—Mr. Ross, who was last week appointed engineer to the Commissioners of Sewers, has issued a report on the subject of the works executed by the Commission during the past year. With regard to electric lighting, Mr. Ross remarks that main thoroughfares to the extent of 13 miles are now lighted by arc lamps. At the end of the year the number of gas lamps unlit was 1,315, and the number of arc lamps lighted was 479—in other words, 2·74 gas lamps were extinguished for each arc lamp. The failures of the arc lamps during the year were not numerous; the percentage of time during the last six months being ·046, or one hour in 2,100.

Result of Islington Tenders.—The number of tenders received by the Islington Vestry for the supply of electrical plant was over 200. The accepted tenders are as follows: Boilers and engines, steam-pipes, pumps, etc., D. Adamson and Co., Dukinfield, Manchester, £8,614. 4s.; water-tube boilers, Babcock and Wilcox, London, £1,170; alternators and switching gear, J. Fowler and Co., Leeds, £3,925. 5s.; instruments, Elliott Bros., 101, St. Martin's-lane, W.C., £830; conduits, British Insulated Wire Company, Prescot, Lancs., £4,333. 4s. 2d. The arc lighting section, including engines and machinery, and also the cables, have not yet been decided.

Douglas.—A meeting was held on Wednesday of the shareholders of the Isle of Man Tramways Company, Douglas, to confirm a resolution passed at a meeting in May to wind up the Company voluntarily, the secretary (Mr. Young) being appointed liquidator. This resolution was unanimously confirmed by the meeting on Wednesday. The winding up of the Company is the consequence of its assets and interests in the tram lines leased from the Town Commissioners having been bought up by the new Douglas and Laxey Tramway Company for £36,000. The price which the Company have obtained for their property will amount to £1. 10s. 4d. for the ordinary £1 shares, which some years ago could have been bought for 6s. or 7s. each.

The Edison-Bell Phonograph.—Judgment has been given in the Court of Appeal in the appeal of the defendants from the judgment of Mr. Justice Wright, in February last, in the action of the Edison-Bell Phonograph Company *v.* Smith and another. The Master of the Rolls dealt with the defendants' objections to the various claims set up for plaintiffs' patent. He agreed with every part of the judgment of Mr. Justice Wright, and he could not disagree with his finding as to matters of fact; therefore, in his final judgment he entirely agreed with him, and he thought

Digitized by Google

that the present appeal had substantially failed in every respect, with the exception of the minor amendment as to relief. The defendants must pay the costs of the appeal. Lord Justices Kay and Smith concurred.

Newcastle.—The city engineer has presented to the Finance Committee a statement as to the probable cost of painting the Town Hall, introducing heating apparatus in the building and lighting up the hall with the electric light. He reported that the painting of the building would cost £430; heating the place, £410; and the installation of the electric light, almost £470. It was decided that the report should be considered at the next meeting of the committee. The Town Council have received the report of the special committee appointed to consider the desirability of the Corporation undertaking the provisions of electricity in the city. The report, which is in favour of the Corporation undertaking this work, was adopted by the Council on Wednesday, and £200 is to be spent in getting information on the subject.

Glasgow.—The Electric Committee of Glasgow Town Council have had before them the proposed extension of the generating plant in the central station in Waterloo-street, the laying of additional distributing mains in the western district of the city, and the application by the Police Commissioners to have several additional streets within the city lighted by electricity. They have remitted to the engineer to prepare a plan, showing what further plant can be accommodated within the Waterloo station, and the probable cost of putting down the same. They have meantime delayed the matter as to supplying current for additional street-lighting until it is ascertained from the annual financial statement what has been the average cost to the Corporation of supplying each of the arc lamps for street-lighting at present in use.

Worthing.—The Electric Light Committee reported to a meeting of the Town Council last week that they had received replies to an interrogatory circular sent to 52 town clerks. The chairman (Councillor Raffety) was requested to obtain the opinion of an expert as to the probable cost of such works and machinery as are requisite to enable the Council to supply electricity for street lamps and to private persons. It was resolved that the chairman, with the mayor and town clerk, should prepare and send a circular to the inhabitants of the borough, inviting them to state whether they are prepared to take the electric light in the event of the Town Council being in a position to supply it. The Council were recommended to direct the committee to take the necessary steps to enable them to apply to the Board of Trade for a provisional order.

Colchester.—The Public Library Committee have reported to the Town Council that they have been in negotiation with Messrs. Christy Bros., of Chelmsford, as to lighting the library by electricity. Messrs. Christy tender to supply the requisite electrical energy at the rate of 8d. per unit, but state that, as they will have to make a very large capital outlay for electric accumulators, they can only undertake the lighting on condition that the Council take the supply for a minimum term of three years. It is calculated that the consumption, with reasonable economy, will be from 1,400 to 1,500 units per annum, at an expenditure of about £50, which will be very little, if any, dearer than gas in similar circumstances. Messrs. Christy also tender to supply and fix the necessary fittings for £28. 4s. The committee recommended the Council to accept the tenders. The report was adopted by the Town Council after some discussion.

Sunderland.—At Wednesday's meeting of the Town Council, on the receipt of the report of the committee on electric lighting, a long discussion took place with regard to the appointment of a resident electrical engineer. The committee submitted the names of the following selected candidates: C. S. V. Brown, 27 years of age, resident engineer, the London Electric Supply Corporation, Stowage Wharf, Deptford, London; John F. C. Snell, 26 years of age, assistant engineer, St. Pancras Vestry's Central Station, London. Alderman Fairless moved that the portion of the report be sent back to the committee, and he contended that they should have the candidates before them, and then make a selection. Eventually it was decided that the two gentlemen named, together with a third, a Mr. Brown, the three recommended by Prof. Kennedy, be invited to wait upon the committee, and that the committee should then elect one of them.

Edinburgh.—At the meeting of the Town Council on Tuesday the treasurer stated that of the capital expenditure of the Lord Provost's Committee there was an increase of £1,580 for electric lighting. There was an estimated charge of £4,785 for electric lighting. Mr. Mackenzie explained that the reason for the large increase in the estimate for the electric lighting station at the West-end was that the committee had decided to make provision for extension at the outset, in order to save the very great expense of enlarging the station, probably within a year. Mr. Cranston, in connection with certain payments to the National Telephone Company by the Plans and Works Committee, took occasion to refer to what he called the very bad service that was given in the town by the telephone company. It was perfectly disgraceful. He did not think any city was so badly served. The telephone company got many advantages from the city, and they gave a poor return for it.

Leeds.—At a meeting of the Sanitary Committee of the Leeds Corporation, the question of erecting boilers of 550 h.p. at the Meanwood-road destructor was considered. The matter was brought before the committee by the city engineer (Mr. Hewson), and it was pointed out that boilers of the power suggested might be utilised for the purposes of electric lighting, or for electric traction or cable traction on the tramways. A sub-committee was appointed to consider the question. It appears that the electrical plant in the Leeds Municipal Buildings is likely to be removed. At a meeting of the Corporate Buildings Committee, a sub-committee was appointed to consider the advisability of having a plant fixed near the destructor, where, it is thought, it could be utilised for other purposes as well as for furnishing the electrical supply required for lighting the Municipal Buildings and Town Hall. An alternative suggestion has been made that the Corporation should obtain their supply from the Yorkshire House-to-House Electric Lighting Company.

Blackpool.—It is expected that the electric tramway will be completed for traffic very shortly. A test of the new portion of the line between the Cocker-street terminus and Foxhall-road has proved satisfactory, and the leakage of current is reported to be very small. Mr. M. Holroyd Smith has been instructed to refuse all tramway boxes not supplied in strict accordance with his orders and drawings. Mr. Thos. Parker has been asked to accept a sum of £10. 10s. in respect of his inspection and report upon the Corporation tramways in December last. Tenders are to be procured for the rails and other ironwork required for the proposed tramways in Lytham-road, and the town clerk has been authorised on behalf of the Corporation to give all necessary notices to companies or persons in connection with the laying of the proposed tramways in Lytham-road. Mr. M. Holroyd Smith has also been authorised to obtain designs and estimates from various makers for the motors and gearing required for the two new large tramway bogie cars now being built by the Lancaster Wagon Company.

Stafford.—The report of the Electric Lighting Committee was presented for adoption by Alderman W. H. Peach at a meeting of the Council last week. He stated that the foundation for the chimney stack had been prepared and 25 pitch-pine piles had been driven and firm ground reached. Similar foundations would be made for the engine and dynamo house. After detailing several minor alterations in the contracts, Alderman Peach drew attention to some remarks in the Birmingham City Council as to the competition between electricity and gas in the Market Hall ward, where a company provided the electric light. In that ward there had been a considerable decrease in the consumption of gas, due to the use of electricity. It was remarked at the meeting referred to that the competition of the electric light was seriously checking the consumption of gas, and the application of electricity to illumination would continue to grow. The Birmingham Corporation would eventually have to buy out the electric lighting company at an exorbitant figure. He mentioned this as a justification of the course they had pursued at Stafford. The report was adopted.

Southport.—At Tuesday's meeting of the Town Council, Alderman Hocking, in moving the minutes of the Gas and Electricity Committee, called attention to a resolution to the effect that the price of electric energy for the first year from the opening of the works be 7d. per unit, being one penny less than the maximum allowed by the provisional order. Councillor Hesford seconded the adoption of the minutes. Councillor Kerr moved, as an amendment, that the price be 6d. per unit. Having studied the subject, he had come to the conclusion that the action of the committee, if endorsed by the Council, would considerably decrease the consumption of electrical energy for some years. Councillor Hough seconded the amendment. Councillor Travis explained that the question had been carefully considered by the committee from various standpoints. They came to the conclusion that there was no reason to believe they could make any profit by supplying electricity at 6d. per unit. It was hoped that in the course of a short time the committee would be able to make important concessions to large consumers. Having heard this explanation Councillor Kerr withdrew his amendment, and the minutes were adopted as recommended.

Derby.—A number of members of the Midland and South Midland branches of the National Association of Colliery Managers lately visited Derby and viewed the works at the electric lighting station. Mr. Stewart (manager of the works), together with members of the staff, conducted the company round the station, explaining to them in detail the working of the machinery and apparatus. After staying an hour at the electric lighting station, Mr. Stewart conducted the company to the electrical exhibition at the Lecture Hall. The chief event consisted of a demonstration by Messrs. Pyke and Harris, electrical engineers, of London, with high-tension apparatus. Some brilliant illuminations were produced, and in many ways the power of electricity was shown. The company included Mr. Douglas (president of the Midland branch), Mr. J. Ashworth (Chaddesden, vice-president), Mr. T. Severn (Nottingham), Mr. Blower (Newton), Mr. J. H. W. Loverock (Riddings), Mr. Wheatley (Nailstone), Mr. Allsopp (Pinxton), Mr. Miles Hardwick (Napperley), Mr. Hodgson (Coton Park, Burton), Mr. Allsopp, jun. (Pinxton), Mr. Jno. Eaton, Mr. T. G. Lees (Nottingham, secretary of the Midland branch), Mr. J. H. Pragnell (Derby), Mr. Alfred Eley (Swadlincote), Mr. Belfitt (Bretby), Mr. F. P. Hewitt (Swadlincote, secretary of the South Midland branch), Mr. A. Knighton (Bagworth), and Mr. Hewitt (inspector of mines).

Radcliffe.—At a meeting of the Local Board, Mr. Cunliffe moved that application be made to the Board of Trade for a provisional order for the supply of electricity for any public or private purpose within the area of the Board's district. He said the desirability of having the electric light was becoming more evident each year, owing to the high price of gas in the district and its inferiority to electricity as an illuminant. The committee appointed by the Board had visited several towns where electric lighting was in operation and that successfully—not only

Digitized by Google

from a useful but a monetary point of view. It might be suggested that their Board should defer the matter until the District Council came into existence. In this, as in many other matters, delays were dangerous, and they were not too soon. There were many reasons why electric lighting should be introduced. He thought it would be advantageous to shopkeepers, and it would most certainly be so to the dyeworks. Gentlemen engaged in the dyeing and embossing trades had informed him of the great value of the electric light in a district like Radcliffe. Though electric light in its present form had only been going on during the last 16 years, £5,125,000 had been laid out for it. Many local authorities were using it, a large number had schemes in hand, many private companies had been formed, and he had no doubt of its value. For the lighting of the streets it would be very serviceable, and he considered they would be only recognising the interests of the town in seeking the provisional order. Mr. Richard Walker seconded the motion. The resolution was carried unanimously.

Bolton.—The scheme prepared by the electrical engineer (Mr. J. H. Rider) for carrying into effect the supply of electric fittings on the hire-purchase system has been considered by the Gas and Electricity Committee of the Town Council, and it was resolved that the scheme be adopted and that the town clerk be requested to prepare a form of agreement to be entered into by persons having such fittings on the hire-purchase system. The engineer submitted an estimate of the cost of the extension of the electric mains into Newport-street, and it was resolved that the works requisite for such extension be carried out. It was also decided that the tender of Messrs. Siemens Bros. for the laying of the requisite cables for such extension be accepted, and the chairman was authorised to arrange for the construction of an additional transformer-chamber at the corner of Newport-street and Great Moor-street. The four mills in Flash-street belonging to Messrs. Ormrod, Hardcastle, and Co., Limited, are about to receive an electric light installation. The plant consists of one large dynamo, capable of lighting 1,300 lamps, and is driven at a slow speed off one of the mill engines. In addition is a small pilot dynamo of 100 lights capacity, arranged to be run off the same shaft or from a small auxiliary engine, as may be required. The current from both machines is regulated at a main switchboard, and is conveyed by four main cables to the four mills and distributed through local switchboards to the various rooms. The contract has been let to Messrs. Bennett and Druce, of Preston, and the designing and arrangement of plant has been carried out by Messrs. Shepherd and Watney, consulting engineers, Leeds.

Electric Lighting of St. Pancras.—The chairman of the Electricity Committee of St. Pancras Vestry (Mr. A. Sweet) made his annual report to the Vestry on Wednesday. He described the past year's business as satisfactory. The total income was £15,022, sufficient to clear off the deficit of the first year—£1,543—and, after paying all the working expenses and £927 in maintaining the works in the highest state of efficiency, to leave a balance of £4,669, out of which interest and repayment of loans had been met. The extension now nearing completion at Stanhope-street station and the station in course of erection at King's-road would, it was hoped, be in working order and available by next winter. The ratio of cost for public lighting for the year by electricity, as compared with gas, was high, but the charge of 6d. per unit made for public lighting was certainly less than a company would charge under similar conditions, and from Michaelmas next the charge would be reduced to 5d. per unit. The supply of electricity to private houses, though not large, was promising, as the number of consumers had doubled during the year. The report was adopted, and the chairman thanked for his services. A letter was then read from the Gaslight and Coke Company announcing that from the close of the current quarter the price of gas supplied for public lighting would be increased from 2s 2d. to 2s. 4d. per 1,000 cubic feet. The Vestry passed a resolution emphatically protesting against the increase, and Mr. Sweet (the chairman of the Public Lighting Committee) said the Vestry could checkmate the company by lighting all the main streets with the electric light, which they would shortly be able to do.

Lighting of Birkenhead.—The Finance Committee recommended at a meeting of the Town Council last week that application should be made to the Local Government Board for sanction to borrow £1,576 for the purchase of land in Bentinck-street and Craven-street as a site for the central station, and also for the sum of £18,424 for the purpose of constructing the station, for providing mains, distributing and other plant and materials for the execution of works, and for the payment of the costs and expense of the Birkenhead Electric Lighting Order, 1890. Alderman Deakin moved the confirmation of the minutes of the Finance Committee, and said the Council had recently sanctioned the purchase of land for the purpose of electric lighting, and the committee recommended that the necessary sum of £1,517 be borrowed. They had been in communication with Mr. Shoolbred, who had been their adviser, and he had informed them that to make the necessary arrangements it was usual for corporations and other bodies to ask power from the Local Government Board to obtain money for the whole purpose at once. Referring to his former estimates, he believed they would not be very greatly varied, and that £20,000 would cover the cost of the first installation. The Finance Committee had by no means hurried the matter forward; on the contrary, it had received the greatest deliberation. Several years had elapsed since the question was first considered, and it was satisfactory to know that in the intervening period valuable experiences of other places had been obtained, and the committee hoped the money would be remunerative. Mr. Gostenhofer seconded the motion, which was adopted.

Canterbury.—The Town Council have received the following communication from Mr. A. J. Lawson, the engineer and manager of the County of London and Brush Provincial Electric Lighting Company, Limited: "The question of the electric lighting of Canterbury has come before my Board on several occasions, and the Board have instructed me that provided two gentlemen of good financial position and influence in Canterbury or neighbourhood would consent to act as directors of the Canterbury Company, each investing £500 (the directors' qualifications under the articles of the association), and that a sum of not less than £6,000 and not more than £7,500 of the first issue of the shares be subscribed locally, we should be prepared to find twice the amount of the local subscriptions, and proceed with the work within the present year. My Board consider that unless local interest in the company be shown, both by subscriptions to the capital and promises of custom to the company when started, it would be undesirable to invest money in the undertaking. In order to ascertain the views of the citizens on the question, and to obtain the information mentioned above, we should esteem it a favour if the Mayor would agree to convene a meeting of the principal citizens at any convenient time within the next fortnight, when one of the directors of this company and myself would attend and explain fully the position of affairs, furnishing such information in our power as might be desired by the meeting" The Mayor is arranging for an interview.

Sheffield Electric Light and Power Company, Limited.—The report of the directors of this Company states that during the 12 months ended December 31, 1893, the Company's energies have been directed to the establishment of a system of underground mains, and to the construction of a new electric light station. The underground mains and station have now been completed, and were opened by the Mayor on March 17, 1894. The accounts of the Company for the past year have necessarily suffered by the interference with the production and supply of current, consequent upon the operations referred to, as well as the disastrous coal strike. The balance of profit for the year is £585 5s. 6½d., which the directors propose to carry forward to the current year. In order to provide capital for the extension of mains into new districts, and to defray the cost of new buildings, works, and machinery, which the development of the business and the increasing demand for current renders necessary, the Board recently resolved upon an issue of £25,000 4½ per cent. debentures and 6,000 ordinary shares; and they are glad to report that such issue was favourably received. Owing to the growth of the Company's business, and its probable development in the future, the directors propose to submit to the shareholders at a meeting which will be called within the next few weeks, an alteration in the Company's memorandum and articles of association with a view of making them more convenient and better adapted to the present status and requirements of the Company. Under the Company's articles of association one-third of the directors retire at the ensuing annual meeting, and accordingly Messrs. George Franklin and Joseph Gamble will retire, being eligible for re-election. The Company's auditors, Messrs. T. G. Shuttleworth and Son, also retire, but are eligible for re-election.

Fareham.—At the last monthly meeting of the Local Board the following letter was read from the electric lighting company: "Fareham, May 28. To the Fareham Local Board: Gentlemen,—I am instructed by the directors of this company to respectfully inform your Board that unless this company can obtain a larger amount of public and private support than has been hitherto accorded them, they do not feel justified in carrying on the business any longer. A considerable sum of money will be required to place the mains under ground, as per the conditions of our provisional order, and unless a larger amount of support could be obtained it would be useless to embark further capital in the business. We trust your Board and the public will give us the requisite additional support, and thereby render it unnecessary for us to advise the Board of Trade of our intention to abandon our provisional order. Should we feel compelled to abandon our provisional order, then the Board of Trade will give your Board notice under sections 65, 66, and 67 of the aforesaid orders, by which your Board will have the option of purchase within two months after the service of the said notice, the value being agreed or estimated in a manner directed by the Electric Lighting Act, 1888, section 2. Premising your Board does not desire to purchase under present conditions, and not wishing to take steps that might place both your Board and this company in a somewhat undesirable position, we would beg to make the following suggestions: the company are prepared to provide 10 arc lamps in lieu of the small lamps now used in the following streets—*i.e.*, one on Wallington Bridge, two in Trinity-street, two in School-road, one in Grove-road, two in Portland-street, and two in Hartlands-road or Quay-street—for an additional sum of £150 per annum for the remaining period of the lighting contract. I trust your Board will consider this proposal favourably, and therefore avoid the loss of a light which we believe is generally appreciated by all.—I am, gentlemen, your obedient servant, Arthur Blake, secretary." It was decided to hold a special meeting on the subject. At this meeting, which was held on Friday last, and after a long and angry discussion, Mr. Blake, on behalf of the company, withdrew his offer respecting additional lighting, and though asked repeatedly to renew the letter from the company, he positively declined, on the ground that after what had taken place he could not ask the shareholders and bondholders for more capital to put wires underground.

Lighting of Cardiff.—In view of the forthcoming inauguration of the supply of electric light, the *Western Mail* has been making

Digitized by Google

investigations on the subject of the comparative cost of gas and electric lighting for the benefit of the inhabitants. As might be expected, the local paper "plumps for" the electric light. In the course of an article it states the town clerk of Bradford intimates that in that town the cost of fitting up premises for the electric light, including switches, is estimated at from 18s. to 23s. per incandescent lamp, exclusive of the service cable, which is laid on by the Corporation at a charge of actual cost only. Mr. W. T. M'Gowen, the town clerk, further states also that "the charge for electricity is 5d. per unit for lighting purposes, and 3½d. per unit for motive power. The price charged for gas is 2s. 3d. per 1,000 cubic feet, with discounts varying from 2½ to 12½ per cent. Both the gasworks and the electricity works are in the hands of the Corporation. It is hardly possible to compare the electric light with gaslight for illuminating purposes, because the advantage of the former over ths latter is so great. Mr. R. Hill-Dawe, the town clerk of Hull, gives the following statement by the electrical engineer of that borough: "There are two gas companies supplying two different districts of Hull, and the electric light mains are laid in about equal portions of the districts supplied by the two gas companies respectively. The rate in one district for gas is 2s. per 1,000 cubic feet, and in the other is 3s. per 1,000 cubic feet. The present rate for all current supplied in both of the districts is 7d. per Board of Trade unit for lighting purposes, and 5d. per Board of Trade unit for use for electric motors. The proportion which this price bears to the gas at 2s. per 1,000 cubic feet is about 2½ to 1, and at 3s. per 1,000 cubic feet is about 2 to 1. We are not in a position to say whether the consumption of gas has been affected to any great extent, as the Corporation are not the owners of the gasworks, but the electric light is being taken up very readily, and fresh applications are continuously coming in. We are, however, of opinion that the greater cost of the electric light in comparison with that of gas is but a small consideration in the light becoming generally adopted, as the main point with intending consumers is undoubtedly the original cost of the house installation, which in some cases means discarding valuable gas fittings and considerable alteration to premises. It is, however, not so difficult to say which is the more economical light, as the general destructive effects of gas on materials and decorations are entirely obviated by the use of the electric light."

Chester.—At the monthly meeting of the Town Council, held on Wednesday, in connection with the electric lighting question, Alderman H. T. Brown moved that the resolution of the Council of October 11 last, determining that the Hope-pole Paddock be the site for the proposed electric light generating station, be rescinded. He said the resolution was passed in consequence of pressure brought to bear upon that Council. The selection of the site was entirely made by the Electric Lighting Committee, and it was not chosen by the engineer (Dr. Hopkinson) who was called in to advise the Council. Dr. Hopkinson had reported in regard to the site, to which objection had been taken on account that the machinery of the station would cause vibration, that smoke would be caused, and the unsightly appearance which the buildings would present. Vibration was considered a matter which would be exceedingly detrimental to the cathedral, which was adjoining; but Dr. Hopkinson thought there would be no risk. If the works were permitted to be erected on the Hop-pole Paddock, the persons residing in the district would be at the mercy of those works. The Electric Lighting Committee had recently visited Oxford for the purpose of inspecting the system of electric lighting in vogue there, and he was under the impression that the members of that deputation had somewhat modified their views respecting the adoption of the Hop-pole Paddock. The dean and chapter had offered to purchase the site for the purpose of an open space for the benefit of the public, allowing the Corporation to retain any portion of the land abutting on the paddock for the improvement of Frodsham-street. Mr. G. A. Dickson seconded the motion. Mr. W. C. Deeley, on behalf of the Electric Lighting Committee, moved a direct negative, pointing out there was only a sentimental grievance, and expressing surprise at the continued objections put forth by Alderman Brown. He wished to say that every engineer who had been to Chester had selected the Hop-pole Paddock *par excellence* for the electric lighting installation station. If the Council had to purchase another site, it would cost some thousands of pounds. Councillor J. Jones (Boughton Ward) seconded the amendment. Councillor Churton remarked that the Council had already decided that the paddock should be used for the purpose of an electric light generating station. The committee which had been to Oxford had returned, he believed, very largely informed. Councillor B. C. Roberts believed that the committee at their last meeting were unanimously in favour of the Hop-pole Paddock not being wanted for the station, but that they would not recommend the Council to sell it to the dean and chapter. Councillor Churton considered it would be perfectly ridiculous to dispose of the paddock. After further discussion the motion was carried by 17 to 13.

Barnet.—The Local Board last week discussed the report of the Electric Lighting Committee. The report stated that the answers received by the clerk to the Board's circular, inviting agreements for the ratepayers to take the electric light, were read by them at their last meeting. It appeared that there were 315 houses in the district over £20 ratable value. Three hundred and fifteen circulars were delivered: 37 ratepayers were favourable to the light, but would not sign the agreement; 26 were undecided; no reply was received for 35; and 19 were not at home. The collector's report stated that a large number of the occupiers declined to have anything to do with electric lighting, on the ground that its adoption might involve the district in considerable expense and so increase the general district rate. Other ratepayers asked that the matter should be postponed until after the election of the District Council; they thought it should form one of the questions on which the election should be fought. Many of the ratepayers agreed as to the badness of gas and to its high price, but they stated that as they had already been put to considerable expense in providing gas fittings, they were not inclined to spend further sums in electric lighting appliances. It had been suggested by several ratepayers that the Board should fit up the houses with the necessary appliances and charge a rent. A letter was then read from the Brush Company offering to give further information. A letter was also read from Messrs. Crompton and Co. to Mr. Morse in reply to a letter addressed by that gentleman to the company. It was as follows: "In reply to yours of the 25th May, the time you give us is too short to say further to-day than that Mr. Albright and myself, as managing directors, are agreed that we should be quite prepared to recommend to our Board the acceptance of the general principle of undertaking for a period of years the risk of running, without any guarantee, the local authority finding the necessary capital. Of course there are many details of such arrangements as these which would require careful consideration, and we should be glad, if the Local Board of Barnet accept the general principle, to meet you, or any member of your committee, to discuss such details." The committee recommended that the Board accept the principle as set out in Messrs. Crompton's letter, and that negotiations be opened with a view to a scheme being submitted to the Board at a subsequent date. Mr. Walker moved, and Mr. Clarke seconded, the adoption of the report. After considerable discussion, however, the following amendment, proposed by Mr. Morse, and seconded by Mr. James, was carried: "That the report be not adopted, but that the Board are prepared to discuss the matter with Messrs. Crompton on the basis of the capital being found by the Board, but without finally accepting the principle that the capital be found by the Board, that being left open for consideration when all the details are before the Board."

Electric Lighting of Hampstead.—The Finance Committee of the London County Council reported on Tuesday as follows: We have considered the application from the Hampstead Vestry for sanction to the borrowing of a further sum of £25,000 for electric lighting purposes on the instalment system for 50 years. On December 5, 1893, we reported on a similar application, and as the Vestry then required to take up only £5,000 the loan was limited to that amount, and as it was for buildings only the repayment was spread over 30 years. The estimate of the Vestry, as then submitted and reported to the Council in detail, amounted to £19,000; but it is now stated that subsequent enquiry has shown that to be insufficient, and hence the present application for sanction to the borrowing of £25,000, in addition to the £5,000 advanced. The revised estimate is made up as follows: boilers and accessories, £5,090; engines and dynamos, £6,140; switchboards, £720; house connections, £300; mains, £4,830; arc lamp-posts, etc., £700; transformers, etc., £1,600; making good paving, £725; meters (100), £400; engineer's commission, £1,000; making a total of £21,505. The Council's engineer considers some of the prices excessive and the value of the works to be £19,647, which, divided in accordance with the probable life of the works, would be £7,893 for 30 years, £11,354 for 15 years, and £400 for five years. The estimate for the construction of the central supply station and offices, and chimney shaft, including clerk of works' salary and architect's commission, is £8,900, of which £8,400 may have a life of 30 years, and £500 15 years. The total amount, £28,547 (£19,647 and £8,900), if taken according to estimated life, would be £16,293 for 30 years, £11,854 for 15 years, and £400 for five years; but as the Vestry has already borrowed £5,000 for 30 years, the item of £16,293 would be proportionally reduced. The equated period of repayment for these reduced amounts works out at 22 years, and for the full amount (£28,547) at 23½ years. We reported very fully to the Council on February 13 last in connection with the St. Pancras case as to the period for which electric lighting loans should be sanctioned by the Council. We then informed the Council that the Local Government Board, after much deliberation and consultation with experts, fixed the period of 25 years for repayment of loans for electric lighting purposes borrowed under their sanction, and the Council after much discussion and consideration of the question in all its bearings adopted the view that 25 years was a proper period to fix for repayment. Although the equated period in the present instance is somewhat less, we think the merits of the case will be met by adopting the same period, especially having regard to the fact that there is no expenditure for land, but for which, if there had been, the full period would have been recommended; the sanction only of the Council being applied for to the raising of the money. We recommend—(*a*) that the sanction of the Council be given to the borrowing by the Vestry of Hampstead of the sum of £23,500 towards defraying the cost of an electric light installation in that parish, at a rate of interest not exceeding £3. 10s. per cent. per annum, and to be repaid by instalments of principal, or principal and interest combined, within a period of 25 years from the date of the loan; (*b*) that the seal of the Council be affixed to the order submitted with the report.

Monmouth.—The following communication from the assistant secretary of the Local Government Board was laid before the Town Council at a meeting last week: "I am directed by the Local Government Board to advert to your letter of the 10th inst. forwarding a copy of report by Messrs. Bramwell and Harris on the competitive schemes for the disposal of the sewage of the borough of Monmouth. When the Town Council have decided what scheme

Digitized by Google

they will adopt, the Board should be furnished with plans of the works and with detailed estimates of their cost, with a copy of the resolution of the Town Council authorising the necessary application for a loan, and with information respecting the assessable value and existing debt for sanitary purposes of the borough. Suitable forms are enclosed." The Mayor remarked that some few days ago, anticipating that he would be asked how they stood with reference to their drainage and electric lighting scheme and Messrs. Bramwell and Harris's report in the matter, he asked the town clerk to write to Messrs. Bramwell and Harris asking if there would be anything ready for the Corporation meeting of that day. The following letter was received from that firm in reply: "We are obliged by your letter of yesterday, and, in reply, beg leave to say that we are afraid that we have very little information as yet to lay before the Council. We will endeavour, however, before Monday to show to you or to the Mayor a plan showing the amount of ground which would be required for the sewage station. The plan of the site at the Old Forge is in hand, but we must, before letting you have this, determine exactly what size buildings are required to contain the electric lighting machinery there. This we are giving our attention to, and we hope to let you have a plan of this probably some time next week. Before anything can be definitely arranged, however, it will be as well, as we have said, to obtain some sort of formal or informal agreement with the owner of the land to be used for the sewage farm. Until this is done nothing definite can be decided, and we gather from the Mayor's letter that the owners of the suggested sites will require to see the plans of the buildings proposed before they would say whether they would consent to 'sell' or 'let' or not." Since then the following letter has been addressed to the town clerk by Messrs. Bramwell and Harris: "I enclose you herein the duplicate of a letter which I have sent to the Mayor by this post; from this you will see that there are some drawings which it will be possible to bring before your Council at their meeting on Monday. I would much prefer, however, that this should not be done, but that the matter should stand over until it is more advanced. I hope in the course of next week to let you have the rough sketches of the buildings necessary for the electric light station if it is placed at the Old Forge." The Mayor pointed out that they could not move in the matter until they got the general report from the experts. They had been asked for a rough design by Mr. C. M. Crompton-Roberts, and a rough design was now to hand, and he formally moved now that it be sent to Mr. Crompton-Roberts, so that he could see their position in the matter. Mr. Morgan asked if any reply had been received from the Duke of Beaufort's agent. The Mayor answered in the negative. He thought it would be better for the town clerk to write and explain that they were waiting for such a communication in order to see their position in the matter. The town clerk was instructed accordingly.

PROVISIONAL PATENTS, 1894.

JUNE 4.

10798. **Improvements in the lighting, and in lamps used in coal-mines and the like by electricity.** Walter William McLauchlan, 14, Irwell-terrace, Lower Broughton, Manchester.

10803. **Improved means for waterproofing fabrics, paper, and the like, and for insulating electrical conductors.** William Thomson and Alfred Ebenezer Mavor, 66, Barton-arcade, Manchester.

10823. **A new or improved process for the extraction of aluminium from certain clays by electrolysis.** Alfred Francis Bilderbeck Gomess, 24A, Alfred-place West, South Kensington, London.

10851. **Improvements in electric railway signals.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Frank Beattie, United States.) (Complete specification.)

10853. **Improvements in electrical accumulators for storage batteries.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (La Société L'Accumulateur Fulmen, France.) (Complete specification.)

JUNE 5.

10917. **Improvements in electric safety fuses or cut-outs.** Sebastian Ziani de Ferranti, Charterhouse-square, London.

10952. **Improvements in electrodes.** Carl Hoepfner, 45, Southampton-buildings, Chancery-lane, London.

JUNE 6.

10967. **Improvements in electrical switches.** John Henry Tucker, 10, Ryland-street, Birmingham.

10978. **Improvements in electric measuring instruments.** Walter Thomas Goolden and Sydney Evershed, 1, Woodfield-road, Harrow-road, London.

11022. **Improvements in alternate-current rectifiers and apparatus connected therewith.** Sebastian Ziani de Ferranti, Charterhouse-square, London.

JUNE 7.

11069. **Improvements relating to the transmission of signals through submarine telegraph cables.** Alexander Muirhead, 124, Chancery-lane, London.

11100. **Improvements in electric dental motor apparatus.** Francis Napier Denison, 4, South-street, Finsbury, London. (Complete specification.)

11059. **Methods of and apparatus for varying the frequency and number of phases in a polyphase electric current and for converting alternating electric currents into continuous currents, and for other purposes.** Henry Augustus Rowland, 55, Chancery-lane, London.

JUNE 8.

11136. **Improvements in the regulation of electric distribution systems.** Reginald Wood, 28, Southampton-buildings, Chancery-lane, London.

11160. **Improvements in apparatus for starting electric motors.** Henry Willock Ravenshaw and Messrs. Easton, Anderson, and Goolden, Limited, 1, Queen Victoria street, London.

JUNE 9.

11211. **Improvements in railway electrical signalling apparatus.** Walter Grimes, 323, High Holborn, London.

11219. **Incandescent electric lamps and sockets therefor.** Charles Albert Hussey, 1, Queen Victoria-street, London. (Complete specification.)

11225. **Improvements in and relating to arc electric lamps.** Henry Revis and Hugo Hirst, 73, St. Stephen's-road, Upton Park, London.

11241. **An improved electric lamp.** Frederick Richard Boardman, 433, Strand, London.

NOTES.

Electric Lighting in Hanover.—The street arc lighting is to be extended.

German Installations.—There are now 8,000 electric light installations in Germany.

Rotthalmunster.—The whole of the street-lighting in this town will soon be electric.

Aberdeen.—The electric light is to be fitted up in the police offices at an expenditure of £250.

St. Thomas's Hospital.—The library of this hospital on the Thames-embankment is lighted by electricity.

Aigle.—There is a movement on foot to construct an electric tramway between Aigle, in the canton of Vaud, and Leysin.

Leek.—The electric light question is, it appears, as far off as ever. Probably this is due to the leaky state of some of the pockets.

Electro-Chemistry.—Chairs of electro-chemistry are to be founded in the Polytechnic Academies of Berlin, Hanover, and Aix-la-Chapelle.

Argentine Republic.—Messrs. Schuckert and Co., of Nuremberg, have received the order to erect a central electric light station at Santiago, in the Argentine Republic.

Wynau.—On the 1st prox. work will be commenced on the central electric light station, for which Messrs. Siemens and Halske have acquired water power. About 4,000 h.p. is available.

Gross-Kanisza.—We have already referred to the electric lighting central station in this Hungarian town. We now learn that the public lighting was to be inaugurated last week.

City and Waterloo Electric Railway. — The works of the new electric railway between the City and Waterloo Station have been commenced by the contractors, Messrs. John Mowlem and Co.

Bunzlau Telephones.—The long-distance telephone system which extended from Bunzlau to Liegnitz, has now been further extended to Berlin. The charge made is 1s. for three minutes' conversation.

Frankfort Accumulator Works.—These works on the Pollak system have been converted into a limited liability company. Mr. Charles Pollak is manager and Mr. Hermann Massenbach assistant manager.

Accumulator Traction.—The management of the tramway company in Hagen, Westphalia, intend to introduce accumulator traction on the section of their line between Markt, Körnerstrasse, and Kückelhausen.

Electromotors.—The use of electric motors in connection with electric light installations is being largely extended in Leipsic, especially in the printing and bookbinding trades, which form the staple industries of the town.

Electric Lighting in Leipsic.—Apart from the central station which is waited for, a number of large firms are introducing private installations not only for lighting purposes, but also for transmission of power.

Ascona. — The works in connection with the electric lighting of this Swiss town are almost completed. The water power of the old Maygetti sawmill is employed. The project has been carried out by Mr. Moja Francesco.

Tottonham.— The Tottenham Local Board have received notice from the Tottenham and Edmonton Electric Light and Power Company of intention to apply for a provisional order to light part of the district by electricity.

Chinese Telegraphs.—Dr. Morrison, who has arrived at Bhamo from Shanghai, reports that the Superintendent of Chinese Telegraphs has received orders from the Chinese Government to extend the telegraph line from Momein to Burma.

An Electric Fleet.—It is reported that the ornamental waters in the parks of the city of Boston are to be equipped with a fleet of about 250 boats, including a number of electric launches, which are to be charged from the Edison circuits.

Electric Lighting at Cahors.—The Municipality have taken action against the gas company to compel them to supply electric light. In the event of the refusal of the company to do so, the town will give a concession from the month of March next.

Electric Tramway at Erfurt.—Official trials have recently been made of the electric tramway, which has been erected on the Thomson-Houston system by the Union Electricity Company of Berlin. A part of the system is now open for public traffic.

Harbour-Lighting at Mayence.—The harbour has hitherto been lighted partially by electricity, four arc lamps and 180 incandescent lamps being employed. The Municipality have now decided to extend the installation to 20 arc lamps and 500 incandescent lamps.

Marmande.—A committee of the Municipal Council has been formed to consider a proposition of the Franco-Belgium Gas Company, who propose to introduce the electric light, and do other work, in consideration of their concession being extended by 30 years.

Indian Telegraph Revenue.—The revenue of the Indian Telegraph Department during 1893-94 shows an increase of four lakhs of rupees on private messages as compared with the previous year, and a decrease of one lakh in expenditure on State telegrams.

Steinau-on-the-Oder.—The streets here have been lighted by petroleum, but the question of lighting them by electricity is under consideration. A concession has already been granted for private lighting, orders from 40 persons for 500 lamps having already been received.

West Metropolitan Tramways.—A Board of Trade enquiry is to be held in respect of these tramways, the proposed sale of which last week was fruitless. Possibly if the Lineff system had been carried out as originally intended, the present position of affairs would not have obtained.

Electric Lighting of Bordeaux.—Attention has been drawn, at a sitting of the Municipal Council, to the delay in introducing the electric light into the town. It was stated that a project was being worked out by a specialist in Paris, who would shortly report to the Council on the subject.

Berlin and Munich Telephone.—Arrangements are being made for the establishment of telephonic communication between Berlin, Leipzig, Nuremberg, and Munich. There will also be connected with the system the towns of Augsburg, Bamberg, Bayreuth, Erlangen, Fürth, Regensburg, and Würtzburg.

The Government and Telephony.—As nothing has yet been seen of the agreement with the telephone company which the Postmaster-General promised to lay on the table as far back as April 30 last, Mr. Jackson intends to ask Mr. Arnold Morley when the publication of the document may be expected.

Electrical Navigation.—An advertiser in a daily paper desires a capitalist to finance a new system of electrical navigation. He says that the method "has been

Digitized by Google

enthusiastically received by influential marine authorities." It is a pity that their enthusiasm was so lukewarm as to induce them not to finance the system.

Laying of New Mains.—The House-to-House Electric Light Supply Company intend to lay mains and construct street boxes in Warwick-gardens, and in Bolton-gardens, Wetherby-road. The Westminster Electric Supply Corporation are about to lay mains on both sides of Chester-terrace, between South Eaton-place and Eaton-terrace.

Plauen (Saxony).—An electric tramway now about to be constructed necessitates the widening of a bridge, which the Town Council have authorised to be carried out. Plauen needs electric traction. It is no joke being there in the winter time, notwithstanding the so-called pleasures of sledge driving and the unintelligible local German dialect.

Shoreditch.—The Shoreditch Vestry have at last agreed to purchase the Pitfield site for an electric lighting station. The price to be given is £33,500. The whole scheme is estimated to cost over £100,000. The Vestry have decided to petition the Board of Trade for an extension of 18 months on the provisional order in which to complete the scheme.

Electric Tramway in Kiew.—About two years ago the General Electricity Company, of Berlin, constructed an electric tramway at Kiew, which was the first in Russia. It has now been decided to extend electric traction to three other routes. There are to be 32 self-contained cars, each capable, in case of need, of drawing a trailer. Overhead conductors are employed.

West Bromwich Tramways.—The object of the Tramways Orders Confirmation (No. 2) Bill is to confirm provisional orders made by the Board of Trade, including an order authorising the construction of tramways in West Bromwich and a portion of Handsworth, in the county of Stafford, and for other purposes. Electrical engineers should look after this enterprise.

Electric Traction on Snowdon.—A public meeting of the ratepayers of Llanberis has been held to consider the advisability of taking measures to make the place more attractive to visitors. It was reported at the meeting that a movement was on foot to construct an electric railway to the top of Snowdon, the name of Mr. Assheton Smith being associated with the scheme.

Neversink Mountain Electric Railway.—We have received a copy of a reprint from the *Electrical World* describing the Neversink Mountain electric road, together with results of tests. The reprint, which is well illustrated, comprises several articles published in that journal from the pens of Messrs. Hermann S. Hering and Wm. J. Aldrich, of Johns Hopkins University.

The Leeds Tramways.—The Highways Committee of the Leeds Corporation had under consideration, on Tuesday, the estimates submitted to the Tramways Committee with reference to the letting of the tramways, and the matter now stands over for the sub-committee to make further investigations, and to visit Newcastle and Edinburgh, where the cable system is in operation.

An Advertising Dodge.—We note, according to the *Financial Times* of Wednesday, that the *Cable Gazette* is being made the means, through the Eastern Extension Telegraph Company, of disseminating news about the plague in Hong-Kong. Evidently the *Financial Times* did not understand that the object of this was to secure a free advertisement for the electrical contemporary in question.

Electric Lighting in Letzwyl.—This Swiss village is to receive the electric light. The community have to pay nothing for the water power, and will supply private lamps at 12s. 10d. per 16-c.p. lamp per year. The cost of the installation, exclusive of the lamp itself, comes to 16s. per lamp. Of the 60 public electric lighting stations in Switzerland none has been able to supply private consumers at so cheap a rate.

Dear Granny.—Dear old grandmother — we beg pardon, the *Daily News*—discovered on Tuesday that a dinner cooked by electricity was given at the Cannon-street Hotel on the previous Friday. Dear granny recently became stouter—in fact, increased her number of pages, but notwithstanding this, she, like the *Times*, does not object to give information that has already appeared days previously in other papers.

Electrically-Heated Cloth-Presses.—An electric system of imparting a gloss to textiles has been patented at the works of Mr. J. Sarfert in Reichenbach, Saxony. The method consists in heating the press plates by the electric current, which is conveyed into the plates by leading-in wires. An illustrated description of the system is given by Prof. E. Müller, of Hanover, in *Dingler's Polytechnisches Journal* of June 15.

Yacht-Lighting.—Messrs. D. and W. Henderson, of Partick, have built the largest steam-yacht ever launched on the Clyde for Mr. Arthur E. Wood, of Newboldlevel, near Rugby. She is lighted throughout with electricity, and is fitted with a very powerful search-light, placed in the fore end of the deckhouse, on a movable platform. The electric installation has been carried out by Lord Claude Hamilton and Co., Limited.

"Medical Electrical Institute."—We regret to notice that the creditors of the "Medical Battery" Company, Limited, have resolved to form a new company, under the title of the "Medical Electrical Institute," to acquire and carry on the old undertaking. If the new company intends to conduct the business on the same lines as those of the old concern, we hope that the present scheme of reconstruction will fall through.

Electricity in Dundee.—At a meeting of the Works Committee of the Dundee Gas Committee held on Tuesday, the question of providing additional plant for the electrical station was discussed, and it was resolved to ask the engineers, Messrs. Urquhart and Small, to prepare a report for the consideration of the Commission. A satisfactory report was submitted by Messrs. Urquhart and Small on the works for the installation as taken over from the contractors.

Electric Cloak Pegs.—To avoid thefts in cloakrooms, Mr. Maurice Salomon is reported to have invented a special peg on which a coat or a hat may be hung. The peg is connected with a small electric battery and bell. When the weight of the coat or hat is on the peg it cuts off the current of electricity and the bell remains silent. Immediately the article of apparel is taken off the peg the bell rings, calling the attention of the cloakroom attendant to the fact of the removal.

Ventilation of Tunnels.—A report has been called for by the Board of Trade from the Metropolitan Railway Company, showing the efforts that have been made by the company to mitigate the effect of the poisonous fumes that are given off in the tunnels in certain sections of their system. The company would be wise in overcoming this difficulty in some manner or other. If they are not yet disposed to adopt electric locomotives, they might erect more ventilating-shafts, with fans driven by electric motors.

Electric Supply in Every City Street.—The City of London Electric Lighting Company notify that they are now in a position to supply electricity for all purposes in every street and lane within the City of London, and in

Digitized by Google

St. Saviour's district, Southwark. Consumers who undertake to use 75 per cent. of their current between the hours of 10 p.m. and 6 a.m. are granted a special rate of 4d. per Board of Trade unit, and this rate is also charged for all current used for heating, cooking, and motive-power purposes.

New Electrical Engineering Works.—According to a German contemporary, a syndicate of capitalists propose to erect at Bayreuth a large works for the manufacture of electrical plant, and more particularly of dynamos. The members of the syndicate have been in the town with two engineers to look for a suitable site. They propose to utilise the water power of the Maine for part of the power required at the works. It is also proposed to enter into negotiatiations with the Municipality for the erection of a central station.

Commercial Cable Company's Cable.—The steamship "Faraday" has picked up the Irish shore end of the Commercial Cable Company's third cable between Ireland and Nova Scotia, which was laid in April, and having spliced on the main, or deep-sea section, is now paying out westward. At noon on Wednesday, the "Faraday" had paid out 175.6 knots from the eastern splice, making a total of 316.7 knots from Waterville, Ireland, the position being lat. 51 44 N., long. 18 17 W. The ship was then passing over the deepest water, and all was going well.

Transmission of Power.—An interesting installation has been carried out by the Oerlikon Works at Mr. C. Scheuffele's paperworks at Oberlenningen, Wurtemberg. The River Lauter furnishes power to the extent of 250 h.p., of which 135 h.p. is made use of for lighting and power purposes. Three-phase alternating-current motors at the generating station supply current at 1,000 volts to the factory, where it is transformed and distributed to the lamps and to various motors. At the works 123 effective horse-power is obtained, so that the loss in transmission is less than 10 per cent.

The British Association.—The *Transactions* of this association for 1893, embodying the report of the Nottingham meeting, have just been published in a volume of over 1,000 pages. It contains the addresses of the president and the presidents of sections, the reports of the many committees that work during the year, and a record of the papers read at the meeting by title, abstract, or text. One paper printed in full is that by Mr. W. W. Beaumont on the automatic balance of reciprocating mechanism, which is accompanied by illustrative figures. The reports include those on standards for use in electrical measurements, and on electrolysis and electro-chemistry.

Electrical Manufacture of Carborundum.—Some months ago the Franklin Institute, Philadelphia, awarded the John Scott legacy premium and medal to Mr. Edward G. Acheson for his discovery of a new artificial abrasive material, called carborundum. In the June issue of the *Journal* of the Franklin Institute the official report is printed with illustrations. The method of manufacture consists in subjecting mixtures of carbon with silica or silicious materials and a flux to an extremely high temperature in electrical furnaces. Carborundum is used for grinding and polishing metals, glass, and precious stones.

Northern Society of Electrical Engineers.—Mr. J. Darney, the hon. secretary of this society, of 4, Palatine-buildings, Hunt's Bank, Manchester, announces that the members will, on Saturday, the 23rd inst., pay a visit to the Liverpool Overhead Railway generating station and the Oldham-place central station of the Liverpool Electric Supply Company. A saloon carriage will be provided on the train leaving the Central Station, Manchester, at 1.30 p.m. Arrangements are being made for an excursion to the Antwerp Exhibition in July. Upwards of 20 members have already signified their intention of joining the party, and Mr. Darney will be pleased to hear from others who are disposed to accompany the party.

High-Pressure Direct-Current Transmission.—With reference to the article on this subject in our issue of May 25, and the comments of Mr. O. Görling on Mr. Schultz's proposal, which appeared in our "Notes" on the 8th inst.—in which the former stated that Messrs. Schuckert and Co. had previously carried out installations of the same character—Mr. Schultz now replies. He states that he has no desire to dispute the claim made on behalf of Messrs. Schuckert, but it would not be permissible to draw deductions therefrom, as he knows of a series installation on this system which has existed for longer—namely, that carried out at Solothurn by Mr. C. E. L. Brown on behalf of the Oerlikon Works. Claims for priority are consequently superfluous.

Direct-Reading Measuring Instruments.—As was briefly recorded by our correspondent in his report last week of the meeting at Leipzig of the Union of German Electrical Engineers, Dr. Th. Bruger read a paper on the subject of direct-reading measuring instruments. He pointed out that while at first physical measuring instruments were of service in electrical work, the progress of electricity resulted in new electrical instruments which were of use in physics. The main point in electrical measuring instruments now was to obtain the desired result quickly and direct without calculations or circumstantial manipulations. The instruments which the author described were those made by Messrs. Hartmann and Braun, of Bockenheim.

Personal.—The statement made by our correspondent in our last issue in regard to Mr. G. Kapp's appointment in Germany is now confirmed by the *Pall Mall Gazette*, which says: "England is losing a well-known and talented electrical engineer in the person of Mr. Gisbert Kapp, who has signed an agreement with the Union of German Electrical Engineers (Verband Deutscher Elecktrotechniker) as general secretary of the union, which has just guaranteed him an annual remuneration of £1,000." The *Indian Engineer* hears that Mr. R. Jamieson Browne, A.M.I.E.E., has proceeded to Afghanistan to superintend the erection of an electrical plant for the Ameer. The private address of Mr. Albion T. Snell, M.I.E.E., from to-day (the 22nd inst.) is South View, Brondesbury-road, N.W.

Laws of Galvanic Polarisation and Electrolysis. In an article on this subject by Mr. O. Wiedeburg, the author sought to give a consistent exposition of the phenomena of galvanic polarisation on the following fundamental assumptions. The ions are driven by the active E.M.F. towards the two electrodes, where they collect and generate new breaks in the potential, which, acting against the original E.M.F., regulate the current according to Ohm's law. All the ions that reach the electrodes, however, are not electrically active, but only a small proportion of them, the rest being neutralised, losing their ionic character, and contributing nothing to the sudden difference of potential. There is a limit to the gathering of the ions at the electrodes, and the relative amount which collects at any instant is smaller the nearer the amount already collected is to the limit, being proportional to the difference between the limiting and actual values at the instant considered.

Electrolysis of Gas and Water Pipes.—A committee was appointed some time ago by the Western Gas Association of the United States to investigate the question of electrolysis caused by street railway return circuits.

Digitized by Google

The conclusions of the committee are summarised as follows: "1. Electrolysis from the grounded currents of electric roads is rapidly injuring gas and water pipes, and it is admitted by street railway people that the injury does proceed from their operations. 2. Complete relief from its action cannot be reached by any device applicable by those injured, but is attainable by certain changes in the electric railways. 3. The gas and water interest should unite in demands for remedial measures which shall secure the adoption of systems undoubtedly effective, and which will thereby avoid a revival of the question a few years hence. 4. Pending the discussion or completion of the relieving systems, the pipes should be protected at the exposed points, at which the policy of increasing the resistance by insulation should be followed rather than that of increasing the conductivity by wiring."

Electric Tramway at Lemberg.—In our last issue we mentioned that part of this line had been opened for traffic. The following particulars have now reached us. In Lemberg, which is the chief town of Galicia, the different sections of the electric tramway amount to a total of about five miles, of which about 3½ miles are now in operation. The gradients of the line are unfavourable, often amounting to 4 and 5 per cent., while at one point is reached 6·75. The curves are also sharp. Phœnix rails are employed for the track. The overhead conductors are carried on cross-wires, which are, according to the character of the surroundings, supported by ornamental iron posts, by ordinary wooden posts, or from walls. The current has an E.M.F. of 500 volts, the return circuit being through the rails, which have copper connections at the joints. There are to be 16 self-contained cars, of which one half is now in operation. The motors are of 25 h.p. Chain gearing connects the motors with the axles. There are two compound steam-engines at the generating station, each of 200 effective horse-power, and each driving direct a Siemens and Halske dynamo.

Damages for Electrical Shock.—In March last, while two men were taking a constitutional in Innsbruck, they discovered a telephone wire hanging down to the ground, when one of them picked it up and promptly yelled for assistance. His friend came to the rescue, knocked the wire out of his hand with a stick, and received a shock which rendered him unconscious. On recovering, he found that the picker up of unconsidered trifles was dead. A court of enquiry has now been held, at which three of the officials of the local electric lighting company were charged with culpable negligence. It appears that they had been warned several times that telephone wires above their conductors were broken, but no attention had been paid to the matter. The telephone wire in question had fallen across the conductor, resulting in the accident. One of the officials has been sentenced to one month's imprisonment, the second to four months' imprisonment, and the third has been discharged. In addition, an indemnity of 100 florins has to be paid to the injured man. Nothing has been awarded to the relatives of the dead man. It therefore appears that in Innsbruck it is less expensive to kill a man than simply to knock him down.

Electrical Conductivity of Gases.—In the *Zeit. Physikal. Chem.*, Mr. F. Braun gives the result of a number of different cases investigated as follows: (1) Compound gases at the moment of formation—The only cases studied were mixtures of (1) nitric oxide and air; (2) chlorine and hydrogen, which were caused to unite by the influence of heat or diffused daylight. A Leyden jar battery of about 4,000 volts E.M.F. was employed. No conduction was observable. (2) Gases during the time of explosion—A mixture of carbonic oxide and oxygen was employed, and a current from seven to twenty small Grove cells was employed; in this case there appeared to be undoubted conduction through the exploding gas. (3) Gases heated to high temperatures—The gases were heated in porcelain tubes to about 1,000deg. to 1,200deg., and the current used was that from a Leclanché cell. Ammonium chloride and cadmium iodide conducted well; ammonia, iodine, and hydrogen chloride conducted, as did to a less extent hydrogen iodide, hydrogen bromide, and probably mercuric oxide. No conduction was observed in the cases of carbonic anhydride, water, and nitric peroxide. The paper closes with a short discussion of the electric charges of flames, which the author considers to be due to a separation of positive and negative ions. The results in general confirm the experiments of De Hemptinne.

Lighting at Bournemouth. — On Tuesday Mr. F. H. Tulloch, M.I.C.E., an inspector of the Local Government Board, held an enquiry at the Municipal Offices into the application of the Bournemouth Corporation to borrow £4,000 for the purposes of electric lighting of the pier and gardens. The Council was represented by Mr. J. Druitt, jun. (town clerk), and Mr. F. W. Lacey (borough surveyor). There was no opposition, and the only members of the public present were the secretary and engineer of the local electric light company. Mr. Druitt, stating the object of the application, said that the Corporation had already erected engines in the pleasure grounds for the purposes of pumping salt water, and now wished to utilise the spare power for the purpose of lighting the pier and gardens by electricity. They had a license to do so from the Board of Trade, extending over seven years, for much wider powers than those they were now seeking. Mr. Lacey said that the two engines in the gardens indicated 80 h.p. each, but for the purpose of pumping they only used one engine for about 12 hours a day. They would require 51 h.p. for the lighting of the gardens, and 45 h.p. for the pier on ordinary occasions, and an extra 20 h.p. on special occasions. The Council had also other property in the Winter Gardens which it was suggested should be lit by the Corporation. He thought they would have sufficient power to work both the electric light and the pumping, and would be able to so arrange matters that it would not be necessary to have the engines working for the two purposes together. Subsequently the inspector inspected the engines and the places proposed to be illuminated.

New Gas Tramcar.—It is proposed to make experiments with a gas-motor car on the single line of tramway connecting Thornton Heath with Croydon, and it is claimed by Mr. B. W. Wallace, Mr. H. P. Holt, and others interested in the enterprise, that gas will be found far less expensive than any other means of traction. A trial trip made on Tuesday demonstrated that the car can travel at any speed between four miles and eight miles an hour, and that it can ascend steep gradients and turn sharp curves with ease. The gas is drawn from the mains and compressed by a pump into a steel cylinder or receiver, at a pressure of 150lb. Thence it is passed into three smaller cylinders concealed in the bed of the car and under the seats. The gas-cylinders in the car can be recharged in two minutes, and it is calculated that the cost of the gas consumed, at 3s. per 1,000ft., is 1d. per mile run. The motor is of the Otto type, and is specially constructed for tramway work. It has a slow and a quick speed, but the latter cannot exceed eight miles an hour—the maximum speed allowed by the Board of Trade. The ignition of the charge in the motor cylinders is effected by electricity, and the cylinders exhaust into a condenser so as to avoid smell causing a nuisance. The charging station is at the depôt

Digitized by Google

of the Croydon and Thornton Heath Tramways Company at Thornton Heath, where an 8-h.p. Otto gas-engine drives the compressor. In Germany, several similar cars are in daily operation. Among those present at the trial were Mr. W. Carruthers-Wain; Mr. J. G. B. Elliott, secretary of the Tramways Institute; Mr. F. O. Driscoll, M.P.; and Mr. P. Holyoake, secretary of the Traction Syndicate, Limited, which has acquired the patent rights in the invention, which is of German origin.

Banquet Cooked by Electricity.—To get custom for current by day as well as by night is a point aimed at by all supply companies. So far there has not been much progress made in this country in the use of motors supplied with current from lighting mains nor in the use of current for heating and cooking purposes. In order to give proof positive of the capabilities of cooking by electricity the City of London Electric Lighting Company, Limited, on Friday evening last gave a banquet thus cooked at the Cannon-street Hotel, showing their confidence in the excellence of their cooking arrangements by inviting the Lord Mayor, who, in his official capacity, is, of course, an excellent judge of what constitutes a good dinner. The hotel has its own electric light installation, but for cooking this dinner a cable was led from behind the hotel from the mains of the City Company. The dinner was prepared in Crompton electrical ovens, which are furnished with four switches so as to control the heating of either the top or the bottom or the sides independently, or the whole of the oven, an arrangement which is exceedingly serviceable. The other appliances included electrical hot-plates, frying-pans, etc. The dinner proved most satisfactory, and in the course of the evening Sir David Salomons, who occupied the chair, proposed the toast of "Success to Electricity," in which he stated that the company were pioneers in electric cookery. They had the satisfaction of knowing that the food had not been spoiled by the taste of gas or the products of combustion. The company charged 8d. per unit for current for lighting purposes, which was dearer than at the West-end, but then they had fewer working days. For cooking purposes they would charge half—namely, 4d. per unit. That evening the number of units used was 60 for ovens capable of providing for 120 guests, the cost working out to ·2d. per course for each guest. Prof. Silvanus Thompson and Dr. Ernest Hart responded to the toast. It may be noted that, appropriately enough in connection with this banquet, the engineer to the company is Mr. Cook.

Royal Meteorological Society.—The closing meeting of this society for the session was held on Wednesday at the Institution of Civil Engineers, Mr. R. Inwards, F.R.A.S., president, in the chair. Mr. R. H. Scott, F.R.S., read a paper on "Fogs Reported with Strong Winds during the Fifteen Years 1876 to 1890, in the British Isles." Mr. R. H. Curtis, F.R.Met.Soc., read a paper on "Some Characteristic Features of Gales and Strong Winds." After calling attention to the unsatisfactory state of anemometry, and after describing the "bridled" anemometer at Holyhead, Mr. Curtis stated that the greatest force of an individual gust which he had met with was registered in December, 1891, and amounted to a rate of 111 miles per hour, which with the old factor would be equivalent to a rate of about 160 miles per hour. Gusts at a rate from 90 to 100 miles per hour have many times been recorded, but the usual limit for gusts may be taken to equal about 80 miles per hour, which on the old scale would be equivalent to about 120 miles per hour. Gales and strong winds differ in character very much; and as the result of a prolonged study of their general features, as recorded by the bridled anemometer, the author has been able to group them into three general classes. He then described those gales which are essentially squally in character, in which the gusts constitute the main feature of the gale. In an average gale the ordinary gusts follow each other at intervals of about 10 to 20 seconds, while the extreme gusts occur at the rate of about one per minute. Another class of gales is those in which the velocity of the wind is tolerably steady. In the third class are gales which appear to be made up of two series of rapidly succeeding squalls—the one series at a conparative low rate of velocity, the other at a much higher one, the wind force shifting rapidly and very frequently from one series to the other. Mr. Curtis also stated that on looking carefully over the anemometer records he had not unfrequently found very distinctly marked a prolonged pulsation in the wind force, which recurs again and again with more or less regularity of perhaps 20 minutes or half an hour in some cases, and in others at longer intervals of about an hour, more or less.

The Stockholm Central Station.—The *Journal* of the Institution of Electrical Engineers contains a description from a German contemporary of this central station. It states the station was begun in October, 1890, and the trial runs took place in July, 1892, the works being opened on September 1 of that year. The buildings have accommodation for the completed plant, but the engine-room and accumulator-house are only calculated for half the amount. The boilers, dynamos and engines, and accumulators are at present capable of supplying 10,000 30-watt lamps. In the boiler-house there are fitted two Babcock and Wilcox water-tube boilers of a heating surface of 1,870 square feet, and room is provided for five more of the same size. Every boiler has 96 tubes of 102mm. diameter and about 16ft. long, divided into 12 groups of eight tubes. The boilers all feed into a common steam service pipe, having a branch to every steam-engine. The boilers are fed by Worthington duplex pumps, which take the feed water from a reservoir below, which receives the condensation water. The fuel used is coke from the town gasworks. The steaming tests gave for every kilogramme of coke (deducting ash) 7·17 kilogrammes of steam, containing 2 per cent. of moisture. The two steam-engines now working are made by W. Lindberg's Company, in Stockholm, and are marine triple-expansion condensing engines. Their normal output is 250 h.p., and can be raised to 310 h.p. as a maximum. The cylinders are 371mm., 594mm., and 965mm. in diameter respectively. At the trials these engines gave a consumption of 5·91 kilogrammes of steam per indicated horse-power at the normal load, and 6·16 kilogrammes at the maximum output. Each engine is directly coupled to a dynamo, the inside-pole machine of Siemens and Halske. These dynamos have six poles, and develop 340 volts and 670 amperes at 100 revolutions. At the trials the output was 330 volts × 686 amperes for 361·4 i.h.p. (German horse-power = 736 watts). They were run for 24 hours, and the rise of temperature of the armature was 35deg. C., and that of the field magnet coils 21deg. The engine-room has room for another similar dynamo of 500 h.p., and there is ground for enlargement. The batteries consist of 280 Hagen accumulator cells, arranged as two double batteries, and the three-wire capacity of the whole is 2,500 ampere-hours. The regulating arrangements are as usual, and the regulation is done by hand. The feeders are connected to the omnibus bars by automatic resistance regulators. The cables are armoured and lead-covered, laid direct in the ground in general, but in iron pipes where requiring protection. The main house fuses are so arranged that the house can be put on either side of the middle wire as required.

PHYSICAL UNITS.

BY MAGNUS MACLEAN, M.A., F.R.S.E.

(All Rights Reserved.)

(Continued from page 693.)

§ 17. The symbols to be used for the three fundamental units are: for length, [L]; for mass, [M]; and for time, [T]. The symbols L, M, T, without brackets, will be used to denote the number of such units in the quantity to be expressed. We have now to determine the relations of the other physical units to these chosen fundamental units, and to examine the laws according to which the derived units vary when the fundamental units are changed from one system to the other system. Every physical quantity essentially consists of two factors: (1) the fundamental unit employed, and (2) a numeric* which expresses the number of times the fundamental unit is to be taken to make up the physical quantity considered. Thus the numeric is the ratio of the physical quantity considered to the unit chosen as fundamental unit. In symbols, if [Q] is the fundamental unit, and Q the physical quantity considered, we have $Q = n\,[Q]$, where n is a numeric as above defined, and may be integral or fractional. Thus in the expression 56 metres, 56 is the numeric n, and metres is the denominational part represented by [Q]. If n is unity, the quantity expressed is the unit.

§ 18. Geometrical quantities are independent of the units of mass and time, and kinematical quantities are independent of the unit of mass, and these may be first considered. Kinematics may be defined as the geometry of motion. It differs from kinetics in not considering (1) the masses of the bodies moved, (2) the forces causing the motion, and (3) any mutual forces called into action between the bodies moved, on account of the motion.

Unit *area* or surface, is that of a square which has unit length for edge. Hence its dimensional formula is $[S] = [L^2]$.

Unit *volume* is that of a cube which has unit length for edge. Hence its dimensional formula is $[V] = [L^3]$.

Unit *plane angle*, called a radian, is the angle subtended at the centre of a circle by an arc equal in length to the radius. Its dimensional formula is therefore length by length $= [L^0]$.

Unit *solid angle* is the angle subtended at the centre of a sphere of unit radius, by unit spherical surface of that sphere. Generally the measure of a solid or conical angle is obtained by dividing the area cut off by the cone from a sphere whose centre is at the vertex of the cone, by the square of the radius of the sphere. Its dimensional formula is therefore $[L^2]/[L^2] = [L^0]$.

Curvature is the angle turned through by the tangent, per unit of length of the curve. Its dimensional formula is therefore $1/[L] = [L^{-1}]$.

Tortuosity is the angle turned through by the osculating plane, per unit of length of the curve. Its dimensional formula is therefore $[L^{-1}]$.

[For an analogy between lines and surfaces as regards curvature, for definitions of *curvatura integra*, *average curvature*, *specific curvature*, see Thomson and Tait "Natural Philosophy," second edition, § 136 and § 138, p. 105 and p. 109.]

§ 19. *Velocity* is rate of change of position in space, and a body is said to have unit velocity when, if the motion be uniform, it passes over unit space in unit time. Its dimensional formula is therefore $[v] = [L]/[T] = [L\,T^{-1}]$. Thirty miles an hour = 44ft. per second.

The dimensional formula for angular velocity is $[\omega] = [T^{-1}]$.

Acceleration is rate of change of velocity, and its dimensional formula is $[a]$ or $[\dot{v}] = [v]/[T] = [L\,T^{-2}]$.

Similarly, angular acceleration $[\dot{\omega}] = [T^{-2}]$.

§ 20. *Momentum* of a body is the product of its mass into its velocity, and its dimensional formula is therefore $[M\,v] = [M\,L\,T^{-1}]$.

* Fourier, "Theorie de la Chaleur," § 160, p. 157; English translation, by Alex. Freeman, M.A., p. 126. Thomson's "Arithmetic," ed. lxxii., p. 4. In this connection a reading of a paper, by A. Lodge, in *Nature*, July 19, 1888, p. 281, on "The Multiplication and Division of Concrete Quantities," is recommended.

Force, by Newton's second law of motion, is proportional to the time rate of change of momentum.

$$F \propto , Ma = \text{constant} \times M\,a.$$

If we define unit force as that force which will produce unit acceleration in unit mass, the constant in the equation will be unity. This is what is done, so that unit force is that force which, acting on unit mass for unit time, will produce in it unit velocity. In the British system, unit force is called a poundal. A poundal is that force which, acting on 1lb. for one second, generates in it a velocity of 1ft. per second. In the metric system, unit force is called a dyne. A dyne is that force which, acting on one gramme for one second, generates in it a velocity of 1cm. per second. If gravity be allowed to act on a mass for unit time, the velocity acquired is g units. Hence the force of gravity is g times the unit of force as above defined.

One pound weight = g poundals.
One gramme weight = g dynes.

§ 21. The force of gravity varies from place to place on the earth's surface. There are two main reasons why the force of gravity at sea-level should be different at different parts of the earth's surface—(1) the shape of the earth, and (2) the rotation of the earth. The earth is not an exact sphere, but more like an oblate spheroid. Its polar diameter is approximately 27 miles less than its equatorial diameter. Hence by Newton's universal law of attraction, stated in § 11, the force of gravity at the equator is less than at either pole. Centrifugal force, however, gives the predominant cause of the variation of gravity. At the equator gravity and centrifugal force act in opposite directions, and at other places on the earth's surface the angle between the direction of gravity and the direction of centrifugal force is equal to the latitude of the place of observation, and their resultant is to be found by the parallelogram of forces.

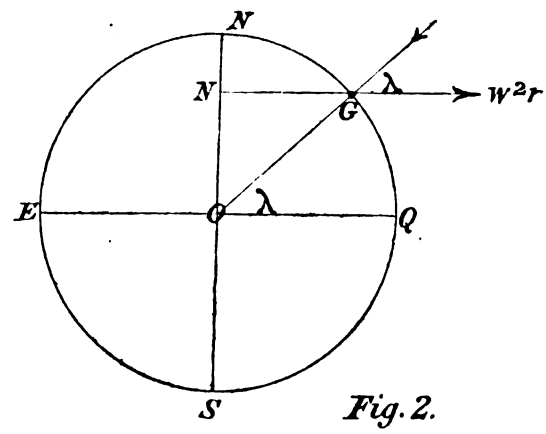

Fig. 2.

§ 22. Let Fig. 2 represent a diametral section of the earth, supposed here to be spherical. E Q is an equatorial diameter, and N S the polar diameter. G is a place on the surface whose latitude is λ. The centrifugal force acting on unit mass, which revolves in a circle of radius r, with angular velocity ω, is equal to $\omega^2 r$. The centrifugal force acting on unit mass at G is along N G and equal to $\omega^2 r \cdot \cos\lambda$, where r = O Q. This may be resolved into two components—one acting vertically against gravity, and one acting horizontally towards the equator. The two components are respectively $\omega^2 r \cdot \cos^2\lambda$, and $\omega^2 r \cdot \cos\lambda \cdot \sin\lambda$. At the equator λ is zero, so that the centrifugal force at the equator per unit mass is $\omega^2 r$. Using the two systems of fundamental units, the centrifugal force at the equator per gramme

$$= (2\pi/86{,}400)^2 \times 637 \times 10^6 \text{ dynes},$$
$$= 3{\cdot}37 \text{ dynes},$$

and per pound $= (2\pi/86{,}400)^2 \times 21 \times 10^6$ poundals,
$= {\cdot}0111$ poundal.

This is approximately 1/289 of the force of gravity at the equator, so that gravity at the equator is diminished by 1/289 of itself by centrifugal force. The two causes together diminish it by $\frac{1}{195}$ or about ½ per cent. At sea-level* on the earth's surface the force of gravity is

* See footnote § 7.

Digitized by Google

very approximately given by the following formula:

$$g = 32{\cdot}088\ (1 + {\cdot}00513 \sin^2 \lambda) \text{ poundals},$$
$$= 978\ (1 + {\cdot}00513 \sin^2 \lambda) \text{ dynes},$$

where λ is the latitude of the place of observation.

The dimensional expression for force is therefore

$$[F] = [M\,a] = [M\,.\,v/T] = [M\,L\,T^{-2}].$$

§ 23. The measure of *work* done is the product of the force acting into the distance through which it acts. This assumes that the displacement takes place in the direction in which the force acts. If it does not, the work done is measured by the product of the displacement into the effective component of the force in the direction of the displacement. The dimensional expression for work is therefore

$$[W] = [F\,.\,L] = [M\,L^2\,T^{-2}].$$

The units for force and work are for clearness put into the following tabular form:

—		Gravitation unit.	Kinetic unit.
Force	British system	Pound weight	Poundal
	Metric system	Gramme weight ...	Dyne
Work	British system	Foot-pound	Foot-poundal
	Metric system	Centimetre-gramme	Centimetre-dyne or erg

In practical electricity a unit of work, called a *joule*, is employed, and is equivalent to 10^7 ergs.

§ 24. *Energy* of a body is the capacity it has for doing work. The gain or loss in the energy of a body is equivalent to the work done upon the body, or to the work done by the body. This is true whether the gain or loss of energy be due to change of configuration or position, or to change of motion. Or, in the usual nomenclature, the work done by the body, or done on the body, is a measure of its loss or gain of energy, whether that energy be what is generally called *potential energy* or *kinetic energy*.

Hence the dimensional formula for energy is the same as that for work:

$$[E] = [M\,L^2\,T^{-2}].$$

The relations between the British and metric units of force and work are:

One pound weight = 453·6 grammes weight.
= 445,052 dynes.
One poundal = 14·1 grammes weight.
= 13,825 dynes.
One foot-pound = 13,825 centimetre-grammes.
= $13{\cdot}56 \times 10^6$ ergs.
= thirteen and a half million ergs.
One foot-poundal = 429·5 centimetre-grammes.
= 421,386 ergs.

(To be continued.)

THE NEWCASTLE TRAMWAY REPORT.

BY FRANK B. LEA.

The *Electrical Engineer* published the other week (see issue of June 8, page 677) the full report of Mr. W. G. Laws, M.I.C.E., city engineer of Newcastle-upon-Tyne, respecting the tramway system of that place, as ordered by the Tramways Committee of the Corporation, and the details therein set forth will provide some useful texts for a brief discourse upon the subject of electric traction.

In the first place, however, it is not desired by the writer to pose in any way as a hostile critic of the views held and expressed by Mr. Laws; the main conclusions to which this gentleman comes are undoubtedly the wisest and safest possible, both generally and as regards the special conditions which govern the Newcastle tramway system.

The engineer, it is stated, was asked by the committee to report upon three different systems of traction—viz., horses, underground electric conduit, and cable or wire rope. In the exercise of their discretion, the Tramways Committee decided beforehand against the use of both overhead electric conductors and accumulators. Probably no one unconnected with battery manufacture (nor for that matter many of those who have to deal with the practical working of accumulators) would raise much of a voice in protest against excluding battery cars from consideration: the steep grades which rule on most of the Newcastle routes would alone serve to show the inadvisability—not to say absurdity—of doubling, or even trebling the weight of cars. But when the committee shuts the door at the very outset upon electric traction by means of overhead conductor wires, one cannot help feeling that they show somewhat ill-advised haste in such an action. Of course they will have considered the question in some form or another, though whether this consideration can possibly have been adequate may well be doubted. The chief reasons urged against overhead wires are strictly of an æsthetic nature; and Newcastle itself—though a town of tolerably clean and interesting streets—can hardly be thought so beautiful that overhead wires would impair the glamour of its highways, or prevent their proper and safe use by the public. Mr. Laws—and every other engineer of experience—would doubtless admit that an overhead conductor system is the cheapest to construct, so far as capital outlay is concerned; and if he were to consult Mr. Alfred Dickinson, of the South Staffordshire Tramways, he would also find out that the cost of operating such a line is less even than when the cable system of traction is employed. Figures, of course, may be twisted into any shape or direction; but if one accepts those put forward by advocates of each system, there is a saving of 1d. per car mile effected by employing electricity. The average cost of cable traction is stated to be 4d. per car mile. Mr. Dickinson vouches for it that the cost on his electric line does not exceed 3d., under no very exceptional circumstances either.

It is, therefore, to be somewhat regretted that the Newcastle Tramways Committee did not at least seek for a report from their engineer which should embrace a system of electric traction admittedly the cheapest to instal, and, in addition, the cheapest to operate, so far as we may judge from the lines already at work in this country—*e.g.*, the South Staffordshire Tramway, and to a large extent the Liverpool Overhead Railway. Questions absolutely depending upon financial points—that is, to put it concretely—the problems of giving quick, cheap transit on an economical basis, can hardly be settled by paying most consideration to æsthetic arguments against something new, such as an overhead wire equipment. The pocket of John Bull is usually the court of last appeal, and it ought to be so in this case.

Had Mr. Laws been instructed to report also upon the overhead conductor system, he would doubtless have made full enquiry respecting this from other engineers, such as Messrs. T. Parker, J. Hesketh, Kapp, E. Hopkinson, etc., who have made a special study of electric traction, and are fully able from experience to say what it can do and what it cannot. Indeed, to judge from some of Mr. Laws's criticisms upon electric traction in his report as it stands, he would have been well advised to do this in any case. The gentleman who seems to be his authority as regards electrical conduit tramways—Mr. W. N. Colam—is an engineer of no mean position, and he has studied, as the writer knows, the Budapest lines on the spot. The details which he thus gives, and the conclusions at which he arrives concerning this system are accurate and fair; indeed for one who, like Mr. Colam, is so professedly an advocate of cable tramways, the description appears to be remarkably unbiassed. The same cannot altogether be said, however, when electric traction is discussed in the report in more general terms. Mr. Laws brings forward as a serious obstacle to the adoption of electric working, the "difficulty of applying any electric system to towns where there are hills to surmount"! Surely, Mr. Laws does not mean to imply that there is an inherent weakness in electric traction which prevents it from overcoming the effects of gravity in the same way that other motive powers can do!

Accepting his figures for the moment, it may very well be that a car which would consume 10 e.h.p. on the level would require 28 e.h.p. to carry it up a grade of 1 in 20, and 36 e.h.p. on a grade of 1 in 10, the speeds being respectively reduced 40 and 60 per cent.; but Mr. Laws

Digitized by Google

cannot get over the fact that a given weight of car and passengers will require just the same power to take it up a given grade at a given speed whether the motive power be electricity, an endless wire rope, steam locomotive, or horses. Why, then, does he bring it forward as an objection to electric working that a car takes more power to run up a hill than on the level? True, there are, on a cable line, as a rule, some descending cars whose momentum under the action of gravity tends, of course, to balance the extra requirements of power for those going up: but the same thing may be said of an electric line. Motors going down grade can, when properly arranged, serve quite well as generators to help the big machines at the supply station in supplying current to those going up; the fact that so far electrical engineers have not attained quite such a pitch of refinement in their work does not alter the principle in any way, and when it becomes necessary to make the extra saving of a small fraction of a penny per horse-power hour, they will soon obtain as efficient a rate of working as with the cable on this point.

Mr. Laws does not give the weights of cars or passengers, etc., on which are based the figures above mentioned, and it is therefore difficult to verify them. What any ordinary electrical engineer would say, however, is that the power required for working a car on a heavy grade increases in amount, as pointed out by Mr. Laws, when the car travels at *constant speed*. To reduce the velocity in anything like the proportion he names ought surely to imply that the output of horse-power on the axle is kept constant. This may be effected with a considerable degree of nicety by electrical adjustments of the car motors, field coils, and armatures; or, again, whilst reducing the speed and the output, the efficiency of the motors may be kept up to the normal degree. As a matter of fact, the only disadvantages under which electric cars in general may be said to labour—as compared with cable cars—consist of the extra car weight due to the motors and gear, necessitating thereby a little extra power in taking the car up hill, and second, the lack of sufficient refinement in electrical engineers to avail themselves of the power now lost in the descending cars.

So far, by the way, there seem to be few or no statistics of a reliable nature, such as station indicator diagrams and car dynamometer records, which would actually prove that the momentum of descending cars on a cable road nearly balances the retarding effect of those going up. Of course, theoretically, one would admit it at once, but theory and practice do not always exactly fit one another.

It is to be regretted that Mr. Laws should have declared himself quite so strongly on this point against electric traction, for there was no need of much discussion about the matter. Electrical engineers are ready enough to admit the splendid results given on cable lines along certain routes, and at present a hilly district requiring frequent services of cars will in nine cases out of ten offer more scope for profitable use of a cable system than any electrical method as yet known. Newcastle is just such a place; the street, whilst by no means beautiful, are not very wide, and an overhead conductor system might conceivably have offered difficulties, though not insuperable, on that score; the cable will do all that is required—will do it well, and cheaply. Other towns, however, need not necessarily conclude that the same conditions will apply in their case; and if their engineers should be called upon to report as to the most advisable system of mechanical traction to adopt, it is to be hoped that they will be given a free hand to go into the whole question, and discuss it properly and fully.

ELECTRICAL SHOP EQUIPMENT.*

BY HOWARD L. INGERSOLL.

Shops, factories, and mills at the present time are, for the most part, well equipped with modern appliances in steam-driven machinery. In a few printing and lithographing establishments, where the necessity of cleanliness is combated by the tendency of belting to fling dust about the room, line shafting has been replaced by a motor in each room. This reduces belting and shafting by a half, and the improvement is quite marked.

The complicated fixtures—shafts, countershafts, pulleys, hangers, and belts—entailed by the common means of transmitting power, present at the same time favourable and seriously objectionable features. In their favour, it may be said that they are well known; improved by all good appliances obtainable; and, in cases where very small work is done, are the best known ways of transmission.

Offsetting this, we have the first cost of material and placing, which is considerable; they always require a great amount of attention and repair, occupy much valuable space, furnish easy and multiple chances for accident and loss of life, and, furthermore, tend to stir the latent particles of dust and dirt, cause them to become an ingredient in the air breathed by workmen and a deposit on all articles within reach. These are objections—serious ones, too—which, in cases of shops supplied with medium and heavy machinery, outweigh the favourable qualities which have made our present equipment the rule.

Considering, first, the betterment of a shop already constructed and running, let us see how changes may be applied. This establishment has its own power plant—boilers, engine, etc. Let the same power plant remain to serve in the new order. With the addition of a generating plant of one or more dynamos, there will be the basis for an electrically-driven manufactory. From the generating plant the current is taken to the separate departments by ordinary means. It is distributed through the department

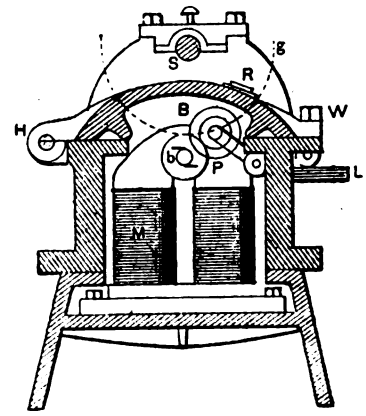

FIG. 1.

by means of a conductor, which may be placed in a similar position relative to the machinery that the line shaft occupied. The hinging point of the change comes here. Each large and independent machine contains a motor in some out-of-the-way part of its frame, which, through gearing, furnishes the driving power.

As to the application of the motor to these various tools, these plans are the result of dynamometer tests with different ones, relative to determining the power required for each under the different conditions appearing in every-day practice. The designs are the outcome of attempting to locate the motor in a protected, yet convenient spot, in the frame of the machine. A complete illustration of this is not necessary, and we will only specify in one or two cases.

First, let us take a lathe. The one experimented with was a 16in. lathe, and various tests were made with different materials, and cut up to the maximum. It was found that under full load (with belt just holding) the power necessary averaged 0·2489 h.p. This includes friction of adjunctory parts used on lathes. Therefore, with a 1-h.p. motor, wound with resistance in series with field, and the range of speed adjusted at 800 to 1,600 revolutions per minute, the requisite change of speed and a considerable excess of power would be realised. The operator has a switch in circuit with the above-mentioned resistance, which enables the regulation (now made by cones) and the reversing to be done. Thus, the overhanging shipper is done away with.

The motor, M (Fig. 1), is located under the headstock, which hinges on lugs, H, at the back of the bed, which

* The *Electrical World*.

Digitized by Google

allows of lifting the headstock to examine the motor. It is the only means of access to the motor, as the cabinet at the head end is a closed casting. The motor rests on a shelf cast on the cabinet, and ribbed for rigidity. The headstock drops on V-ways and the wrist-bolts, W, at the front clamp it solidly in place.

The motor shaft and armature are represented by *b* in Fig. 1, and the pinion, P, is of such a ratio to *g* (gear between bearings on spindle) as will give proper velocity ratio for highest speed. R is the operator's regulating switch on top of headstock. B is the back gear, operated by a stop-lever at L. The back gear is thrown in by offsetting *g*. This gear, *g*, has an extended hub on one side, through which is a stop or pin fitting into a hole in the lathe spindle. To set *g* for back gear, it is moved from the face-plate into the position above the pinion on the back gear arm; then the gear *d* on B, which is above P and gears with it, and the pinion *a* on B are thrown into gear by L. See Fig. 2.

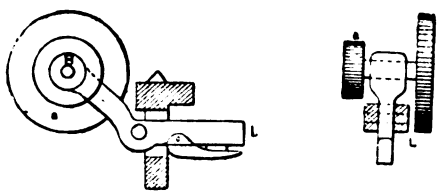

FIG. 2.

This makes a compact arrangement, the motor being entirely hidden and at the same time readily accessible. The screw cut, feed, and other details are applied in a similar manner to ordinary lathes.

The planer offers a ready location for the motor underneath the bed, on a cast shelf, enclosed, and free from dirt. The difficulty to be overcome is the reverse and quick return. The solution to this is quite simple. It necessitates a friction-clutch between two gears on the planer spindle. These gears, Fig. 3, are of different size (*g* and G). P is the pinion on the motor, Fig. 3, and is so arranged as to drive an idler, I, gearing with the quick return gear, *g*, on the spindle of the planer. Another pinion at a distance = *d* from P drives the feed, or forward gear, G, direct.

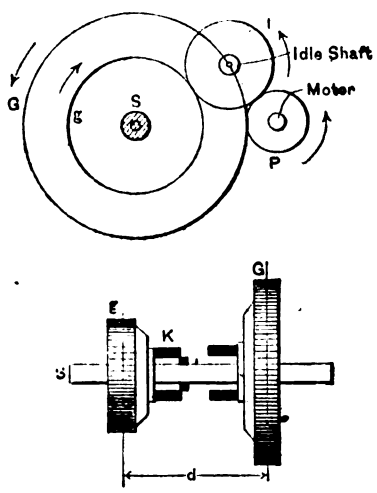

FIG. 3.

Thus we obtain a slow cut, and by having *g* the requisite ratio to P, we can have any quick turn desirable. The clutch, K, is operated by a shifter on the planer table, such as is ordinarily used for shifting belts. The motor is always rotating in the same direction, and, furthermore, the friction-clutch between *g* and G throws the load on gradually. If desired, a switchboard can be used to give changes of speed. The coupling to a shaper may be made in a similar manner, with the exception that the clutch is unnecessary, the Whitworth quick return being entirely sufficient. The motor would be placed in the bottom of the casting, and geared to the quick return of the common shaper.

For a drill press, the connections would be similar to a lathe, the motor either boxed at the base, and the stepped cones and belt used to connect power with spindle, or placed on a shelf beside the spindle and geared to it.

For driving power for small machines—grinding machines and the like, a few of which are necessary in any shop—belting would probably be indispensable. The cost of these machines, supplied with an independent motor, would be so much compared with their earning capacity that it would be useless to put independent driving mechanism in each. Therefore, it would seem that the surplus power of some large machine might serve the few small tools. The lathe, or other large tool, would be connected to the others by belting, placed along walls of the room so as to be out of the way. The motor in this lathe could be run, whether it were used to propel the gear on the lathe or not. Thus it would furnish an ever-ready power for the small sub-tools. The small amount of belting and necessary adjuncts to consummate this would not be a factor.

The arguments for and against present methods in equipment have been given above, together with the advantages to be derived by a change. The only valid argument against this projected method is the cost of these specially-built machines. However, when once the manufacture is undertaken, and the machinery given a fair trial, its advantage will be proven clearly. It may be said here that the writer knows of two large firms, builders of machine tools and their accessories, who are experimenting along these same lines. One of them has a line of tools on the market.

To return to the question of economy. The extra cost of the motor would be small compared with the cost of additional labour required to attend shafting and repair belts. Further, the work of one man will be more productive when the system is tried. Besides this, nothing has been said of the cost of keeping a shop in a cleanly condition, which would be much decreased by avoiding belting. In the case of an old shop, while the utility would be unquestionable, yet the advantage of a change might be uncertain, owing to the expense. But where a new equipment and new establishment are planned, economy and all other considerations point to the fact that the first additional outlay would be well placed.

The noisy and dirty workroom will be changed to a place of quiet and orderliness, and be a matter of pride to the proprietor who has had the wisdom and foresight to keep pace with the tireless march of progress, and the workers in these places will have better nerves, senses, and lungs.

PRACTICAL NOTES ON DYNAMO CALCULATION.—III.

BY ALFRED E. WIENER.*

(Continued from page 703.)

In the last section of this article, Chapter 3, on "Conductor Velocity," was omitted. It is given below. Also the headings of Tables IV. and V. were interchanged—that is, the table under the heading "Table IV.—Practical Field Densities in English Measure," should have been placed under the heading for Table V., and *vice versâ*. Formula (5) should read as follows:

$$S = \frac{d'_a \times \pi}{12} \times \frac{N}{60}, \quad \ldots \quad (5)$$

In formula (6) the second equality sign was misplaced; it should be:

$$d'_a = \frac{12 \times 60}{\pi} \times \frac{S}{N} = 230 \times \frac{S}{N} \quad \ldots \quad (6)$$

3. *Conductor Velocity.*—Since it is cheapest to increase the E.M.F. of a dynamo by raising its speed, it will be best economy to run a dynamo at as high a conductor velocity as practically as possible. The cutting speed of an armature is limited mechanically as well as electrically; friction in the bearings, strain in the revolving parts due to centrifugal force, and heating of the armature, caused by hysteresis and eddy currents in the iron, play an important part in determining the proper conductor velocity. Furthermore, if the number of revolutions of the armature is fixed,

* The *Electrical World*.

Digitized by Google

either by its mechanical limit, or by the speed of the engine in case of a steam dynamo, or otherwise, then the above mechanical and electrical limitations alone are not sufficient for choosing the cutting speed; for too high a velocity, for instance, permissible from all other considerations, would excessively increase the diameter of the armature, and consequently would bring the size of the whole machine entirely out of proportion to its output.

TABLE III.—Mean Conductor Velocities.

Capacity in kilowatts.	Conductor velocity, in feet per second.—Belt-driven dynamos.—Drum armatures.	Belt-driven dynamos.—Ring armatures.	Direct-driven dynamo.

800	—	95	45
1,000	—	95	45
1,500	—	100	45
2,000	—	100	45

In modern high-speed (belt-driven) dynamos the value of S for drum armatures varies from 25ft. to 50ft. per second, and for ring armatures, which offer a better ventilation, and are much lighter than drum armatures of the same diameter, ranges between 50ft. and 100ft. per second. In slow-speed (direct-driven) machines, velocities from 25ft. to 50ft. per second are employed.

In the average values of S for various classes and sizes of dynamos are compiled.

8. *Dimensioning of Toothed and Perforated Armatures.*—Armatures with toothed and with perforated core discs, which have been much used in recent years, offer the following advantages over smooth armatures: (1) excellent means for driving the conductors; (2) mechanical protection of the winding, especially in cores with tangentially projecting teeth, and in perforated bodies; (3) lessening of the resistance of the magnetic circuit, and therefore saving in exciting power; and (4) prevention of eddy currents in the conductors. Their disadvantages are: (1) increased cost of manufacture; (2) greater difficulty of insulating the winding from the core; (3) eddy currents set up by the teeth in the polar faces; (4) additional heat generated in the iron projections by hysteresis; and (5) leakage of lines of force through the armature core.

The latter disadvantage, however, is cancelled by the advantage of reducing, by lessening the magnetic resistance, the necessary exciting power in about the same degree as the leakage would otherwise increase it. The amount of this core leakage depends upon the relative sizes of the slots and the teeth, and, if the armature is otherwise properly dimensioned, will vary within the following limits:

TABLE XI.—Core Leakage in Toothed and Perforated Armatures.

Ratio of width of slots to their pitch on outer circumference. $\frac{n' \times s}{d''a \times \pi}$	Factor of armature leakage—Toothed armatures—Straight teeth.	Projecting teeth.	Perforated armatures.
0·4	1·40 to 1·35	1·55 to 1·50	—
·45	1·35 to 1·30	1·50 to 1·45	—
·5	1·30 to 1·25	1·45 to 1·40	1·50 to 1·45
·55	1·25 to 1·20	1·40 to 1·35	1·45 to 1·40
·6	1·20 to 1·15	1·35 to 1·30	1·40 to 1·30
·65	—	—	1·35 to 1·30
·7	—	—	1·30 to 1·25

On account of this core leakage, toothed and perforated armatures are to be designed for lower field densities than smooth ones; for values of practical field densities for straight-tooth armatures of various sizes see columns 4, 5, 10, and 11 of the previous Tables IV. and V. respectively, and for corresponding values for projecting tooth –, and for perforated cores, columns 5, 7, 12, and 13 of the same tables.

(*a*) *Toothed Armatures.*—The mean winding diameter, d'_a, of a toothed armature being determined by means of formula (6), its core diameter, or diameter at bottom of slots, d_a, Fig. 1, is obtained by deducting from d'_a the height of the winding space, or in this case, the depth of the slots, h_a, averages for which are given in the fourth column of Table XV., Chapter 9. The outside diameter of the armature, d''_a, over the teeth is obtained by adding h_a, from Table XV., to d'_a, from formula (6).

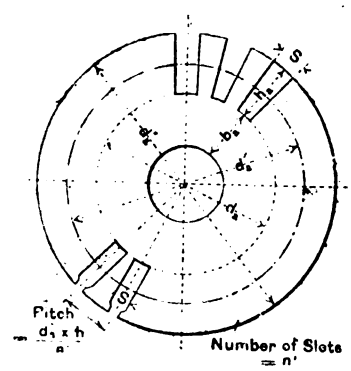

FIG. 1.

The number of the slots, n', depends upon the size of the armature. Practice has shown that better results are obtained from deep and narrow slots than from shallow and wide ones, and in consequence a large number of slots is preferable to a small one. The following are good practical limits:

TABLE XII.—Number of Slots in Toothed Armatures.

Diameter of armature, in inches. $d''a$.	Number of slots. n'.	Diameter of armature, in inches. $d''a$.	Number of slots. n'.
5	30 to 50	50	150 to 200
10	40 to 70	100	200 to 300
20	60 to 100	150	250 to 350
30	100 to 150	200	300 to 400

As to the width of the slots, its relation to that of the teeth is governed by the following considerations: On account of the disadvantage of the teeth creating eddy currents in the pole-pieces, their width ought to be small compared with that of the slots; in order to reduce the hysteresis loss in the teeth, and the heat caused by the same, to a minimum, the mass of the teeth should be small, and their area perpendicular to the flow of the lines, hence their width, large; for the sake of effectively reducing the magnetic resistance of the circuit the teeth ought to be as wide as possible; and in order to prevent an excessive core leakage, finally, a small width of the teeth should be chosen. Summing up all these conditions, a good practical rule seems to be to make the width of the slots

$$s = \frac{d''_a \times \pi}{2 \times n'}, \quad \ldots\ldots \quad (7)$$

that is to say, to make the width of the slots equal to half their pitch on the outer circumference; for the special case of a straight-tooth core, then, the width of the slots is equal to the top width of the teeth.

Applying this rule to armatures of various sizes, the writer has calculated the following table, giving dimensions of toothed armatures:

TABLE XIII.—Dimensions of Toothed Armatures.

Diameter of armature, in inches d''_a.	Dimensions of slots—Depth, in inches h_a.	Width, in inches s.	Ratio of depth to width. $h_a : s$. (*b*) *Perforated Armatures.*—The same considerations that prevailed in determining the number and the width of the

Digitized by Google

slots in toothed armatures are also decisive for the dimensioning of perforated cores. The number of perforations, for this reason, can be taken in the same limits as the number of slots for toothed cores. See Table XII. In case of round holes, Fig. 2, the thickness of the iron between two adjacent perforations should be taken between 0·5 and 0·75 times the diameter of the hole.

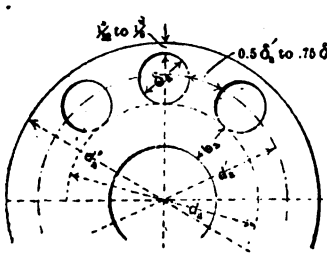

FIG. 2.

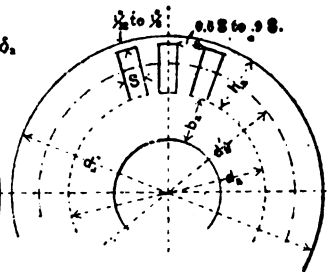

FIG. 3.

For rectangular holes, Fig. 3, the thickness of the iron between them is to be taken somewhat greater than for round holes—namely, from 0·6 to 0·9 times the width of the channel.

The distance of the holes from the outer periphery is to be made as small as possible, and may vary between $\frac{1}{32}$in. and $\frac{1}{8}$in., according to the size of the armature.

9. *Length of Armature Core.*—The number of wires that can be placed in one layer around the armature circumference and the depth of the winding space determine the total number of conductors on the armature, and the latter, together with the length of active wire, gives the length of the armature core.

(*a*) *Number of Wires per Layer.*—For smooth armatures the number of wires per layer is obtained in dividing the available core circumference by the thickness of the insulated armature wire. If the whole circumference is to be filled by the winding, then

$$o = \frac{1{,}000 \times d_a \times \pi}{\delta'_a} \quad . \quad . \quad . \quad (8)$$

where o = number of armature wires per layer;
d_a = diameter of armature core in inches;
δ'_a = width of *insulated* armature conductor in mils. (See Chapter 10.)

In case the winding is to consist in separated coils, the sum of the separating spaces is to be deducted from the armature circumference.

The value of o is to be rounded off to the nearest lower even and easily divisible number, and, in the case of a drum armature, allowance for division strips, or driving horns, is to be made according to Table XIV. This table gives the average circumferential space occupied by the division strips in drum armatures of different sizes and various voltages, in per cent. of the core circumference. After fixing the number of armature divisions, which will be shown in Chapter 11, this table may also be used to determine the thickness of the driving horns, which are usually made of hard wood or fibre, and sometimes even of iron.

TABLE XIV.—Allowance for Division Strips in Drum Armatures.

Diameter of armature core, in inches.	Percentage of core circumference occupied by division strips— Up to 300 volts.	400 to 750 volts.	800 to 2,000 volts.
Up to 3	12%	15%	—
,, 6	10	12	15%
,, 12	8	10	12
,, 20	7	9	10
,, 30	6	8	9

Denoting one-hundredth of these percentages by k, the core circumference being unity, the formula for the number of wires per layer in a drum armature becomes

$$o = \frac{1{,}000 \times d_a \times \pi \times (1 - k)}{\delta'_a} \quad . \quad . \quad . \quad (9)$$

In toothed armatures the number of wires in one layer is found from the number, n', and the available width, s', of the slots by the equation:

$$o = 1{,}000 \times n' \times \frac{s'}{\delta'_a} \quad . \quad . \quad . \quad . \quad (10)$$

In this formula the value of s' is to be derived from the actual width, s, of the armature slots (Chapter 8), by deducting the thickness of insulation used for lining their sides, data for the latter being given in Chapter 10.

(*b*) *Height of Winding Space—Number of Layers.*—In dividing the available height, h'_a, of the winding space by the height, δ''_a, of the insulated armature conductor, the number of layers of wire on the armature is found:

$$u = 1{,}000 \times \frac{h'_a}{\delta''_a} \quad . \quad . \quad . \quad . \quad . \quad (11)$$

u = number of layers of armature wire;
h'_a = available height of winding space, in inches;
δ''_a = height of insulated armature conductor, in mils.

The height of the insulated armature conductor, δ''_a, in the case of round or square wire, is identical with its width, δ'_a.

The available height, h'_a, of the winding space is obtained from its total height, h_a, averages for which are given in Table XV., by deducting from $\frac{1}{32}$in. to $\frac{3}{16}$in. (see Chapter 10), according to size and voltage of machine, for the insulation of the armature core, insulation between the layers, thickness of binding wires, etc.

The nearest whole number is to be substituted for the value of u.

(*c*) *Total Number of Armature Conductors—Length of Armature Core.*—The product of the number of layers and the number of conductors per layer gives the total number of conductors on the armature, and this, divided into the total length of active armature conductor, furnishes the active length of one conductor—that is, the length of the armature body:

$$l_a = \frac{12 \times L_a}{\frac{o \times u}{p}} = \frac{12 \times p \times L_a}{o \times u} \quad . \quad . \quad . \quad (12)$$

where l_a = length of armature core parallel to pole faces, in inches;
L_a = length of active armature conductor, in feet, from formula (3);
o = number of wires per layer, from formula (7), (8) or (9), respectively;
u = number of layers of armature wire, from formula (10);
p = number of wires stranded in parallel to make up one armature conductor of area $\delta_a{}^2$, formula (4);

$\frac{o \times u}{p}$ = total number of conductors on armature.

For preliminary calculations an approximate value of the number of conductors, K, all round the pole-facing circumference of the armature may be obtained by dividing the conductor area found from formula (4) into the net area of the winding space. Taking ·6 of the total area of the winding space as an average for its net area in smooth armatures with winding filling the entire circumference, we obtain:

Digitized by Google

$$\frac{o \times u}{p} = K = \frac{1{,}000{,}000 \times \cdot 6 \times d_a \times \pi \times h_a}{\delta_a{}^2}$$

$$= 1{,}885{,}000 \times \frac{d_a \times h_a}{\delta_a{}^2} \quad . \quad . \quad . \quad (13)$$

This result is to be correspondingly reduced for windings filling only part of circumference, or to be multiplied by $(1 - k)$, see formula (9), in case of a drum armature respectively.

In toothed armatures the average net height of the winding space is about three-fourths of the total depth of the slot, hence the approximate number of armature conductors:

$$\frac{o \times u}{p} = K = \frac{1{,}000{,}000 \times n' \times s' \times \frac{3}{4} h_a}{\delta_a{}^2}$$

$$= 750{,}000 \times \frac{n' \times s' \times h_a}{\delta_a{}^2} \quad . \quad . \quad . \quad (14)$$

In (13) and (14) the values of d_a, h_a, and s' are given in inches, and $\delta_a{}^2$ in circular mils.

(To be continued.)

RELATIVE ADVANTAGES OF TOOTHED AND SMOOTH CORE ARMATURES.*

BY ALTON D. ADAMS.

The merits of different methods of construction in the manufacture of dynamo-electric machinery, as in other lines, must evidently be decided by their comparative costs, all else being equal. Although questions concerning the relative merits of toothed and smooth core armatures have long been discussed, very little seems to have been written to show whether actual saving in cost may be effected by one construction over the other, when employed to produce the same results. The practice of dynamo-builders in this country and abroad embodies both types, and the history of the art records many changes from each to the other. In view of the above, the enquiry, whether in the light of present facts any saving can be effected by the use of toothed-core armatures, seems of interest. The limits of this paper do not permit consideration of this question in connection with all classes of electrical machinery, and its bearing on direct-current constant-pressure machines only will be taken up.

The principal advantages of toothed compared with smooth core armatures are greater first cost, large change of lead, excessive sparking, when used with too short air-gaps, and the production of heat in pole-pieces; their advantages are that inductors are positively driven, large solid inductors protected from eddy currents, and that a reduction may be made in the length and consequent magnetic resistance of the air-gap. Change of lead may be fixed within any desired limits, and sparking abated by such proportions of air-gap and teeth as give the sufficient magnetic resistance. Heat in pole-pieces may be reduced by their lamination, by the use of very narrow teeth and slots, by forms of teeth that present a nearly continuous surface of iron to the pole-pieces, and still more, by the use of openings in core discs which do not cut through their outside surface, or a continuous magnetic sheath outside the teeth. For any given form of tooth the heating of pole-pieces is less the longer the air-gap.

The mechanical strength of armature teeth as usually employed is far in excess of that required to hold inductors in position, even under conditions of short-circuit, and driving pins inserted in the core, at proper intervals, are much cheaper and take up less valuable room on the armature circumference. Either teeth or substantial driving pins are, of course, preferable mechanically to the slender bits of hard fibre which have been much used, and frequently give way under the heavy strains to which large generators are subject. When large wires of copper rods are used as inductors, their protection from eddy currents is an important matter, but proper stranding of inductors reduces the eddy loss in them, when used on smooth cores, to a very small amount, and has the further important advantage that inductors may be bent into the proper shape at armature ends, and the joints, when necessary rods are used, avoided.

The chief possible advantage, then, to be gained by the use of toothed armatures is through a reduction in the length of the air-gap, and the consequent reduction in the ampere-turns required on field magnet, weight of copper, or energy in winding, and the length and weight of iron core. To make this advantage available, it must be practical to use air-gaps shorter than are required for insulation, winding, and clearance. As is well understood, the armature winding of a dynamo or motor in operation has a magnetising action, which is measured in ampere-turns for a bipolar machine, by one-quarter the product of all the inductors of the armature into the total armature current. The ampere-turns on the armature evidently tend to set up a flow of magnetism, having a complete circuit through the armature core, twice across each air-gap, and through the iron of pole-pieces. About half the ampere-turns furnished by the inductors under pole-pieces evidently act against the field ampere-turns in each air-gap at the polar tips, and the ratio between the armature and field ampere-turns at this point, necessary to give sparkless reversal there, must determine whether the required magnetic resistance be greater or less than that of an air-gap long enough for insulation, winding, and clearance with a smooth-core armature.

As an armature coil in an operating dynamo or motor passes under the brush, the current flowing in it must stop, and one in the opposite direction be set up; and if this action is to be accomplished without sparking, a sufficient E.M.F. must be provided in the coil while in direct contact with the brush. In the ordinary dynamo or motor, magnetism forced across the path of the coil by the field ampere-turns expended in air-gap must provide this reversing E.M.F. The data of a number of smooth-core armature machines of different make show ratios of field to armature ampere-turns in air-gap of from about 1 and 1½ to 1 to 2 and 1½ to 1, and the writer's experience is that a ratio of 2 to 1 will give sparkless operation at full load, with brushes set just outside pole corners.

It is a matter of common experience that the ratio between field and armature ampere-turns in the air-gap may be so reduced, even in machines with smooth-core armatures, as to require excessive change of lead to secure even approximate freedom from sparking. If it be desired therefore to build machines having an expenditure of field ampere-turns in the air-gap not much greater than those of the armature, we need not resort to toothed cores. Take, for example, the case of a 260-ampere dynamo, with 120 inductors on its armature in one layer; an air-gap induction of 25,000 lines per square inch, and 80 per cent. of inductors under the pole-pieces. An air-gap of ·45in. between the armature and each pole-piece will be sufficient for insulation, winding, and clearance, and the field ampere-turns expended in each air-gap will therefore be 3,500, while the armature ampere-turns active under each pole tip will be 3,100. A considerable change of lead and sparking can be readily predicted for this machine.

In some types of small machines, the room required by insulation, winding, and clearance makes the air-gap longer than necessary for sparkless operation, and in such machines the utility of teeth seems to depend on their cost compared with the saving to be effected by their use. As the ampere-turns furnished by the inductors under any pole-piece grow less in a machine of given capacity when the number of poles is increased, very short air-gaps may be used, if the number of poles is sufficiently large. As an increase in the number of poles usually makes a machine of given capacity more expensive, however, the question at once comes up, to what extent the number of poles may be increased without a greater expenditure than the saving of iron and copper to be effected.

In large multipolar machines of four or six poles such as are commonly used, the length of air-gap required for sparkless operation is considerable, and those who have watched the development of these machines with toothed-core armatures during the last four or five years have seen the air-gaps gradually widen until machines of this character are not hard to find in which the copper inductors between the teeth could be taken out, wound outside

* A paper read before the American Institute of Electrical Engineers.

Digitized by Google

the teeth, and still leave room enough for good clearance. Additional mechanical security, of course, furnishes a considerable argument for the use of teeth in very large slow-speed machines. A number of devices have been suggested from time to time, to enable toothed-core armatures to be used with short air-gaps, and the consequent saving in iron and copper effected. No machine with these devices, however, have yet stood the test of time and competition with those of ordinary type, and have yet to prove their ability to produce results, as at present attained at a less cost. The seeming opportunity to save material by the use of toothed armatures is very attractive, and we cannot but hope it may some day be practical; in the light of present knowledge, however, there seems little to be gained by their use in medium and large bipolar machines.

DYNAMOS FOR CHARGING ACCUMULATORS.

Dynamos used for charging accumulators, writes M. W. Rechniewski in *L'Electricien*, have to fulfil certain conditions which are not always very convenient, especially in the case where the same machine has to charge the accumulators in the day and serve at night for the supply of current direct to the lighting mains. It is necessary under these conditions that the machines should work at 110 volts in the evening for lighting, and that the voltage may be

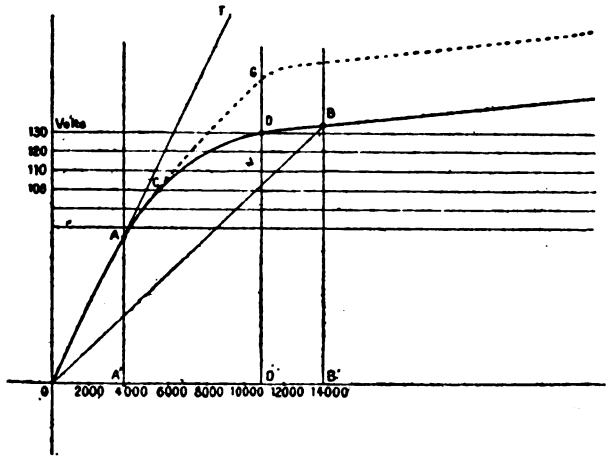

FIG. 1.

increased to 155 or 160 for charging the accumulators in the day. The difference of voltage is still greater when there is an appreciable loss in the line. Supposing the loss is 10 volts at full charge, it will be necessary that the dynamo should furnish 110 volts at a low charge for lighting, 120 volts at full charge for lighting, and 170 volts for charging accumulators. It is necessary that the machine should work under these different conditions without sparking, and that the running should be steady. That is the difficulty.

It is evidently easy to construct a machine working at 170 volts, but when we have to run it at 110 volts it has no steadiness, or the voltage increases beyond 110 volts, resulting in considerable variations in the lamps. Besides this, as the excitation for 110 volts is much reduced, it is almost impossible to run properly without sparking with such low charges. This inconvenience can evidently be remedied by varying the speed of the dynamo proportionately to the voltage required. This method would be admirable from the point of view of working the dynamo, which would thus run at a constant saturation, but it is impossible to employ it. In most cases in practice it is necessary to run at a constant speed. The steadiness of the voltage can also be assured by exciting the dynamo by the accumulators; by this means all the voltages can be obtained in a steady manner, but good running is not assured as regards sparking.

Further, it will not be possible to run satisfactorily without accumulators, which is very inconvenient, as a stoppage will be necessitated while the accumulators are disconnected when being cleaned or repaired.

Considering this problem, first, from the point of view of steadiness, we will take, for example, the characteristic presented in Fig. 1, which is that of a normal 20,000-watt dynamo. It is known that the tangent α of the angle $B\,O\,B^1$ is proportional to the resistance of the exciting circuit of the dynamo. By varying this resistance by moving the exciting rheostat, the voltage of the machine can be varied and a given resistance corresponds with a given voltage, provided that this angle α shall be less than that made with one of the abscissæ by the tangent O T of the characteristic at the beginning.

If the resistance becomes greater, the dynamo would become unsteady immediately. But it can be seen that the characteristic confounds itself with the tangent during a tolerably long course, in this case from O to A—that is to say, for the value of the exciting resistance corresponding to the angle $A\,O\,B^1$, the voltage may take any value between O and $A\,A^1$. There is consequently unsteadiness.

The dynamo cannot, therefore, work practically below $A\,A^1$ volts, and, moreover, it is prudent to keep above this extreme value. In the case of our figure, it would be inadvisable to descend below the point C—that is to say, of 100 volts. On the other hand, the heating of the field magnets does not allow of exceeding an excitation of 11,000 ampere-turns, corresponding to about 130 volts. The margin for this machine is thus only 30 volts. This margin, further, is reduced when we remember that the characteristic only represents the working of the dynamo running unloaded, and when loaded the reaction of the armature, as well as the inevitable slackening of the speed, considerably lowers the margin which has been found.

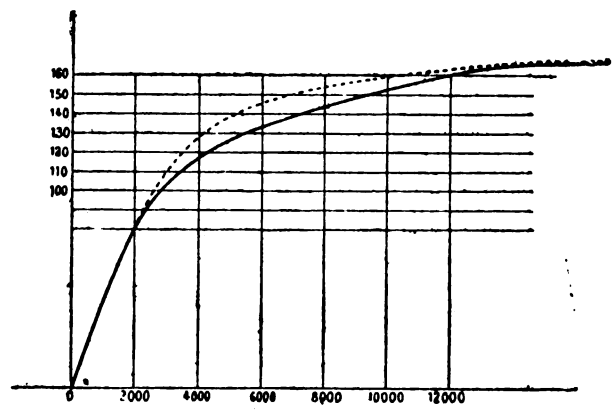

FIG. 2.

If on leaving the point C, where the running is even, one could prevent the characteristic from inflecting more, and make it take, for example, the direction of the dotted tangent in Fig. 1, we would arrive, for the maximum excitation allowed, $O\,D^1$, at a final voltage much higher, and at a sufficient margin for even running at 110 volts, as well as at 170 volts.

This is the manner in which the firm of Messrs. Postel-Vinay have solved the problem. In order to obtain a characteristic of the form in question, they employ armatures with very fine teeth, which are already saturated for 100 volts, whereas the field magnet and the armature are still far from the point of saturation. This saturation of the teeth of the armature produces the first bend of the characteristic at about 100 volts. From this moment everything happens as though the intervening iron of all the height of the teeth had been increased—that is to say, the characteristic again becomes rectilinear, but with a more feeble inclination than before, and this up to the moment of saturation of the field magnets and the armature where the characteristic inflects definitely and tends to become horizontal. The plain line of Fig. 2 represents the characteristic of a machine constructed on this principle, and it will be seen that the running, which is even at 100 volts, can still reach 150 for an excitation of about 9,000. The margin of 50 volts, which is found here, is more than sufficient, the loss of charge on the line being insignificant in this case. The same principle serves for regularly over-compounded dynamos. The dotted line in Fig. 2 shows what would be the characteristic of a machine made on the ordinary principle for 150 volts. It will thus be seen that the limits of even running are very nearly approached.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

PACIFIC CABLE ESTIMATES.

We have kept our readers fairly well acquainted with the course of events which have occurred in connection with the Pacific cable scheme. It might, however, be well to recapitulate the salient points. The one great objection to the present system from the Imperial point of view is that at many points it is not under our own control, and, therefore, in a case of dire necessity would be practically useless to us. We do not mean to cast any reflection upon the existing system because it is not wholly under our own control, because it was originated and has been extended to a large extent from a mere consideration of commercial questions. The system, however, has been and is very largely subsidised, and therefore cannot wholly escape being examined in the light of Imperial questions rather than being kept absolutely within the bounds of commercial considerations. The system, too, is practically a monopoly, and such a monopoly rarely or never takes into consideration the wants of its customers till it is compelled so to do. This certainly has been the case with regard to the Eastern Cable Company and its connections. We contend that neither its customers nor its shareholders have ever been properly considered, nor have they received the returns which they might legitimately have expected in both directions—the one by remission of tariff, the other by an extension of dividend. It does not matter why, but some of the Australian colonies, the American colonies, and a good many of the business people in this country have become desirous of connecting Australasia to England through a cable which shall be wholly under English control. As we have so often stated, the present holders of the monopoly have strenuously exerted themselves to prevent such a cable being laid. We pointed out that this would be the case, and we also foretold that if the laying of a cable became imminent, the present holders of the monopoly would do all they could to obtain the control of this link in the telegraph chain.

It would require a volume to adequately criticise the various statements from this interested opposition, but it will suffice for our purpose if we give a brief digest of the method of climbing down which has been pursued in a recent and somewhat lengthy correspondence carried on in the columns of the *Times* regarding the establishment of a cable across the Pacific. In this correspondence one cannot but be struck by the graceful ease with which the opponents of this scheme vary the results of their estimates. Let us take these *seriatim*, premising that in every case the scheme is credited with an annual Government guarantee of £72,000.

(1) In a protest submitted to Lord Ripon by the "existing companies" it was pointed out that, taking the present traffic between Europe and Australasia at 1,300,000 words annually, any company undertaking a cable across the Pacific would find an annual deficit of £120,000 in their accounts.

(2) In speaking of this project, Sir John Pender informed the shareholders of the Eastern Extension Telegraph Company at the last annual meeting that £165,000 per annum would have to be made up by

Digitized by Google

the earnings of the line. He goes on to say that as the value of the *whole* existing traffic with Australasia, if directed to the Pacific, would only produce about £90,000 at the proposed reduced rates, there would still be a deficit of £75,000 to be made up (this means that if the Pacific cable took only *half* the traffic the "deficit" would be £120,000—*see supra*).

(3) In a letter to the *Times* dated May 30, Sir John Pender estimates "loss to investors" at £48,000.

(4) In a letter to the *Times* dated June 6, Sir John Pender estimates loss to investors at £10,000.

To the above varying figures we may add that, if the traffic for the year 1893 be correctly stated in the Australian papers, it is over 1,401,000 words, which is about 7¾ per cent. more than the figures taken in the above estimates; this would mean another "climb down," leaving a "loss to investors" of only £6,500. With the above varying results in view, it is evident that a little judicious persuasion might prevail on Sir John Pender ultimately to show a balance on the credit side of this account, instead of £120,000 against it.

If we have correctly stated the case, no one can for a moment suppose that the figures which have at various times been put forward have been put forward with any desire to be accurate, but purely and solely with the desire to obtain an adverse influence to the project. We always have inclined to the opinion that where a *bonâ fide* increase of facility is given to business men, there always is and there always will be an increase of business. The history of the Australian negotiations with the Eastern Extension Telegraph Company and others has been full of choppings and changes, variations of tariff, playing off one colony against the other, and, generally, no real attempt to meet the wishes of the colonists with any liberal spirit. In the consideration of this Pacific cable scheme, we have, then, to admit that there must necessarily be an extremely long length of costly cable with no earning capacity from branch lines, or practically no earning through the Pacific except from the American coast to the Australian coast. Its revenues will have to be derived from the two ends of the systems, rather than—as is the case with the existing system—from these ends combined with the various points where the cable is tapped. That is the great commercial objection to it, but its promoters maintain that, with the facilities they are prepared to give, the business from the ends will be, when combined with the subsidies, sufficient to guarantee the shareholders a fair dividend. From the consideration of the adverse criticisms we should be inclined to think that their statements are fairly correct, otherwise Sir John Pender would not have varied his deficit from £120,000 to £10,000. A critic who admits these great variations having, as he ought to have, all the facts of the case before him, is not worthy of credence; and we trust full consideration will be given to the statements made by the promoters of this scheme as to its earning capacity, and this, combined with the admitted utility from the Imperial point of view, ought to enable the scheme to be carried through.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

"OUR REVIEW OF REVIEWS."

SIR,—My free copy reached me this morning. Sam says he got three. He then turned up the "County Councillors' Directory," and remarked that the names came in handy. I notice that Gas "Meter" hashed up something about Portsmouth and the stage and society. I do not know what the stage and society have to do with it. Years ago the engineering papers described the Holden system of burning liquid fuel. Gas "Meter" now trots this out as a new thing. Mr. Kapp discourses on the electricity works at Cologne and Amsterdam. I know the former (but forget about the latter) was described in the electrical papers two years ago, and the working results for two years have already been published in the English journals. But anything is new in a sheet which is not a journal. Sam then came across two columns of padding, called "Our Review of Reviews." He says it is a handy fill-up for want of something better. The padding, probably abstracted before the owner left Bedlam, contains a pat on the head for your French contemporary *L'Electricien* in the fashion of you kiss me and I'll kiss you. The *Revue d'Electricité* is snarled at, and the French journal *La Nature* is drawn upon for half a column. It is so wonderful, Sam says, how well they understand French. The Waterhouse meter, which you described last week, now turns up again. Mr. Chestnut, jun., then fills up some pages of padding on commercial matters which everybody read in the financial papers a fortnight ago. The *Contract Journal* is apparently drawn upon for a copy of the programme of the meeting of the Association of Municipal Engineers, and also, it would appear, for announcements of open tenders. The final padding is a copy of a letter addressed by Mr. Maxim-um-joke to the daily papers. Your contemporary has been unable to find room for the numerous columns of American matter usually given. Poor old "William," too, seems to be absent. Perhaps the cake he ate at the Institution conversazione has not yet been digested. All the same, I hope to see his cheery face again next week, when I shall be able to again give you "Our Review of Reviews."—

Yours, etc.,
JOHNNY.

Timbuctoo, June 19, 1894.

REFUSE DESTRUCTORS.

SIR,—In your leader of last week's issue, in calling attention to the possible results to be obtained in town-lighting by utilising the waste heat in the process of burning house refuse, you quoted Prof. Unwin's estimate of the quantity of refuse collected from each individual as varying from one to four tons per annum. This is rather a wide margin on which to base an engineering calculation, and you very rightly in your remarks used the inferior limit indicated. It is, however, pretty generally known to municipal engineers that this quantity of one ton per head of the population is much in excess of the actual collection, which rarely exceeds half a ton per head. Had you before penning your remarks looked at Mr. Jones's book, to which you referred, on refuse destructors, you would have found many statistics bearing on this point, the best being perhaps the table giving particulars of the London vestries, from which it appears that a population of two and a half millions produce three-quarters of a million tons of refuse, or three-tenths of a ton per head, per annum. Then again, the quantity of refuse required to produce 1 h.p. you quote as 40lb.: this result may possibly be obtained at some future time, but up to the present I believe 1 i.h.p. for 60lb. is about the nearest approach to your figures which has been realised in actual practice on a large scale. If, therefore, you divide the amount of refuse you calculated on by 3 and knock a further 60 per cent. off your horse-power results, you will then more nearly arrive at a fair estimate of the power available for lighting purposes. After this deduct your losses in transforming and leads, and bearing in mind

Digitized by Google

that street lamps are required to run 14 hours out of 24 in the depth of winter, you will, I think, arrive at the conclusion that, however successful the system of storage of power may be, there is not even sufficient power for public lighting alone, without going into the question of private lighting. No good purpose can be served by taking exaggerated views of questions of this sort, and although I am quite prepared to admit that the waste heat produced in destroying town refuse is not utilised so much as it might be, yet, on the other hand, the general public should not be led to suppose that there is a gold-mine in it, as at one time they were taught to believe about sewage sludge.—Yours, etc.,

E. J. SILCOCK.

King's Lynn, June 18, 1894.

THE PORTSMOUTH CENTRAL STATION.

SIR,—We have read with much interest the report of the Portsmouth Corporation works in your issue of the 8th inst. It is, we believe, admitted by all that this plant, as designed by Messrs. S. Z. de Ferranti, shows great developments, and in many respects is novel and original.

May we, therefore, be permitted, through your valuable medium, to correct what appears to us a misprint in the detailed description of the "alternators." "Mica tubes" are therein mentioned. The insulation for this machinery was, however, supplied by us, and the word "mica" should read "micanite." You are probably aware that this insulator is a form of mica insulation, until introduced by us, almost unknown in this country, or even Europe. Since we claim by this patented process to be able, as in this case, to show infinite advantages over the old method of mica insulation, we trust that you will give publication to this letter.—Thanking you in anticipation, yours, etc.,

BERGTHEIL AND YOUNG.

ELECTRIC LIGHTING FROM THE GAS POINT OF VIEW.

The inaugural address before the Incorporated Gas Institute was delivered on Tuesday by Mr. John West, M.I.C.E., president. In comparing the cost of electricity and gas, the PRESIDENT said:

A short time ago an opportunity was afforded me of impressing upon the gas consumers of Manchester the desirability of improving their present antiquated system of gas-lighting, by adopting the modern regenerative or other economical burners, whereby rooms may be ventilated and an equivalent light obtained at a cost from 2½ to 3½ times less than the Corporation would be able to supply the electric light for, from a large central station, as the following calculations will show:

Incandescent Electric Lamp.—16-c.p. lamp lasts 1,000 hours, and absorbs 60 units of electricity at 8d. per unit, 40s.

Ordinary Gas-Burner with Manchester Gas.—16-c.p. is equivalent to 4 cubic feet of gas per hour, or 4,000 cubic feet in 1,000 hours, cost of which at 2s. 6d. per 1,000ft., 10s.

In the above calculation I assumed that the Corporation charge the Board of Trade limit of 8d. per unit for the electric light; and even at that figure grave doubts exist in my mind if they would be able, after paying working expenses, repairs, and maintenance, and providing for a sinking fund, to hand over any profits to the Council, as is at present done by the gas department.

As a proof that lecturing is useful, I was attending only three weeks ago a meeting of general engineers in Manchester, and was asked by the president (at the desire of some of the members) if I would explain to the meeting what were the best and most suitable burners to adopt. The question arose from the reading of a lecture given by Prof. Lewes at the Society of Arts, where he stated that if the best and most scientific burners were used, the gas bills would be reduced. I, of course, did my best to explain the principle of combustion and the theory upon which good burners were constructed; and I advised them as to the best burners to use, so as to obtain the greatest amount of light from the gas, which would enable them to reduce their gas bills—that is, if they were satisfied with the same light that they had formerly obtained. They were so interested in the subject that I am to be called upon to further enlighten them on some future occasion. If the advantages of gas are so great over the electric light where the ordinary flat flame was used in Manchester, how much greater must be its advantages when regenerator and incandescent burners are employed, in which 3¾ cubic feet of gas produce a light of from 70 c.p. to 80 c.p. at about one-eighth the cost of the electric light.

A number of the general public do not seem to be aware that the electric light is produced chiefly from the same source as you produce light—viz., from coal; the difference is that you make the light-giving gas by the distillation of coal in closed vessels, and that, after the gas has been produced, you have valuable products left. In fact, you utilise the energy in the coal more completely, in a commercial sense, than the electrician can; and this enables you to produce a given quantity of light from gas from three to three-and-a-half times cheaper than the price for which the equivalent electric light can be sold so as to produce the same profit that is being derived from the manufacture of gas. If some of the public like to pay for the electric light as a luxury, there is no doubt that installations within reasonable areas, with gas-engines as the motive power, will be found the most reliable and economical, and, from a sanitary point of view, far better than the large number of steam-boilers that are being put in our midst for the purpose. Only a few days ago I inspected an installation of electric lighting at a hotel not very far from this building. There were two large semi-portable boilers with undertype engines, and a large room set apart for containing storage batteries for supplying a few hundred incandescent electric lamps; and this plant required at least two men to look after it during the 24 hours. The whole thing looked ludicrous in my eyes, when I knew that many of our village gasworks are erected and managed for a less sum than this single electric installation.

It is now a well-known fact that a gas-main will deliver sufficient gas to generate 5,000 h.p., or as much more as you please, at a long distance—say, three or more miles—at from three to four times less than the same power can be transmitted for by electric cables. Again, the "load-factor" is a great drawback to the electricians. They cannot store their energy as you do in your gasholders; hence their fuel account comes out very high per unit produced. In many cases they use the best boilers and steam-engines; and they will tell you that they can produce, with 2½lb. to 3lb. of coal, one Board of Trade unit. In practice, however, if you look at the accounts of the electric light departments, you will find that they have, in some way or other, used in many cases about 12lb. of coal per unit, and how to get over this difficulty has been taxing the brains of electricians for a very long time. I find, from calculations, that the Gaslight and Coke Company deliver from Beckton to London—a distance of seven miles—through only two of their mains sufficient gas per hour to produce, in ordinary gas-engines, about 125,000 h.p., the power expended in transmitting this quantity being less than ¼ per cent. of the total. It would be interesting to know the cost of an electric cable to convey this power the same distance, and the loss in transmission.

GAS-ENGINES FOR ELECTRIC LIGHTING.

The members of the Société Industrielle du Nord de la France on May 30 had presented for their consideration a paper by M. Aime Witz, on "The Price of Energy Supplied by Gas-engines." The author first referred to the experiments which, as mentioned in this journal some time ago, showed that more light could be produced by driving dynamos by gas-engines than by burning the same quantity of gas in gas-burners. He then detailed how gas companies had been obliged to establish in their own interests central electric light stations to protect their threatened monopoly. The initiative in this movement had been taken, the author observed, in Germany, but

Digitized by Google

there were now 16 stations in France where the motors were gas-engines.

As these stations adjoined the gasworks, the companies were able to retain their consumers, who would discontinue their patronage if the gas companies would only supply them with gas. M. Witz estimated that, generally speaking, it was possible under these circumstances to supply a hectowatt-hour at 10 centimes, at the same time realising a fair profit, and he established this figure after a detailed examination of the working expenses, interest, and redemption. But in many cases consumers would derive considerable advantage by organising among themselves and erecting sub-stations for the supply of a small collection of houses in rich districts. The owners of cafés, hotels, and large warehouses and a certain number of houses could by combination provide themselves with light at a low cost, and for this purpose it would only be necessary to lay down a motor and a dynamo. M. Witz found that with gas at 15 centimes per cubic metre, the annual price of 150,000 lamp-hours with 16-c.p. lamps worked out at 5·33 centimes per hectowatt-hour. When the consumption is increased to 450,000 lamp-hours the price becomes reduced to 4·18 centimes, and to 3·52 centimes in the case of 1,500,000 lamp-hours. These figures are based upon balance-sheets in which provision had been made for interest and redemption at 15 per cent., but without allowing any profit. But the expenses are much reduced, because the wiring of a collection of houses as mentioned does not extend any distance. Central stations may, then, fear competition from groups of houses served by a dynamo driven by a gas-engine. If the gasworks will only supply their gas at a too high price, then the gas-engine must be furnished with poor or inferior gas In this case, the cost price per kilowatt-hour is further diminished. The following are the figures given by the author for a group of 1,000 lamps (65 kilowatts):

INITIAL COST OF INSTALLATION.

Supply of water and gas (meters)	£120
One 120-h.p. gas-engine	1,200
Foundation, installation, and piping	232
Shafting and belts	200
Dynamo and cost of erection	500
Conductors and accessories	348
Total	£2,600

WORKING EXPENSES (FOR 97,500 KILOWATT-HOURS).

Rent of engine-room	£40
Wages of attendant	48
Gas	743
Water	39
Oil	101
Interest and redemption at 15 per cent.	390
Various	11
Total	£1,372

Thus we have the following figures:

Cost of establishment per lamp	£2	12	0
Cost price per kilowatt-hour	0	0	3½
„ per 16-c.p. lamp hour	0	0	0¼

The author concluded by mentioning various examples of this kind.

THE GAS AND ELECTRICITY SUPPLY OF BLACKPOOL.*

BY WILLIAM CHEW, M.I.E.E., BLACKPOOL.

To the members of this institution, consisting of gas engineers, the part of this paper having reference to electricity may, perhaps, be thought a subject foreign to their interests. At one time, no doubt, this would have been the case; but the development of electrical knowledge during recent years has placed in the field previously held by gas a new agent, as a competitor therewith, for lighting, heating, and motive power. As this new agent seems destined to create a disturbing element in the future prospects of the gas industry, and as the advisability, or otherwise, of having a dual supply is occupying the attention of local authorities throughout the country, I propose in this paper to lay before you an account of the work undertaken at Blackpool which I trust will be of interest to the members generally. The town of Blackpool, as most of you are aware, is the seaside watering-place of Lancashire. Its requirements may therefore be taken as typical of those of other towns, and the grounds on which the Corporation decided to have a dual supply are also applicable elsewhere, though perhaps in a less degree.

Commencing with the gas supply, as being the oldest and most important undertaking, let us examine how far it has fulfilled its purpose, and wherein lie the shortcomings that render it at all necessary to have an auxiliary supply by means of electricity. Without going into ancient history, which is well known, as to the origin of any gasworks, it is evident that at some time or other the Blackpool Corporation became possessed of such works, and at the present time, in addition to their original purpose of lighting only, have added that of supplying an agent for cooking, heating, and motive power. Experience has proved to them that for these purposes the use of gas has been well adapted and thoroughly reliable; and that, from a monetary point of view, it could be sold remarkably cheap in comparison with other agents, and at the same time yield a handsome profit on the investment. However satisfactory these results in the use of gas may have been in the past, we must not overlook the fact that advances have been made of late years in matters of hygiene, and already this class of criticism has been brought to bear on the use of gas, with a view to discourage its adoption wherever possible. Exception is now taken to the combustion of gas in the production of light, and in this lies the chief advantage attributable to electricity as a lighting agent. Under ordinary conditions of usage, light from gas is obtained by combustion—the waste products and heat generated being radiated in the surrounding space; and should this happen to take place in a badly-ventilated room, it will tend to further vitiate the air thereof. Further, with some classes of burners an amount of unconsumed carbon is released, and this combines with the deleterious particles floating on the atmosphere of rooms, depositing itself at times in inconvenient places. I am aware that these drawbacks to the use of gas have been greatly exaggerated and apply only in a slight degree in the majority of uses to which gas is put. But taking as an example an ordinary apartment, where gas is only used about four hours out of the 24 on an average, we find so many counteracting agencies at work, that any chemical theories built upon the basis of the constituents of burning gases are rendered almost neutral in their application, owing to the circulation set up in a heated room from unseen sources. Were this not the case, owing to the depletion of oxygen and the increase of carbonic acid that can be calculated to have taken place in a room through the use of illuminants—such as gas, oil, or candles—the same would soon become uncomfortable for habitation, but such does not happen where ordinary ventilation is allowed to take place. Nevertheless, we find that there are a good many cases where ventilation is neglected, and circulation takes place in a haphazard sort of way; and as the tendency of the age is to have much more light than formerly, the result in such instances is an aggravation of existing evils. It is in this direction, then, that gas scientists must turn their attention if they are to meet these modern requirements; and already there are signs of a new era dawning for the production of light from gas, on the lines of the Welsbach burner, which, besides cheapening the cost of light, has far higher hygienic properties than previous burners in use—so much so that already its sale has had a marked effect in limiting the use of electric light on the Continent, where the burners have been introduced on a large scale. These are the principal arguments advanced against the use of gas, and it is with a view to obviate these drawbacks that some sections of consumers are turning their attention to electric lighting. We know that the requirements of all consumers are not alike in this respect, and that there are a certain number to whom it is a matter of importance to have a lighting agent giving a low calorific effect, with freedom of combustion and a certain convenience of manipulation. To these the question of cost is sometimes a secondary consideration in comparison with the advantages supposed to accrue indirectly. It was for this reason, and on the assumption that there were many of this class of customers in our town who could well afford to pay for such lighting if made available for them, that our Corporation decided to put down an electricity works to supply the central parts of the town.

Before finally deciding to proceed, opportunity was taken to enquire into the demerits as well as the merits of the new system and its properties generally, in comparison with gas lighting. The plant required for its production was found to be much simpler than gas plant, a rotary alternator driven by an engine being all that was required to produce it on a large scale. But the distributing plant was more complicated, owing to the absolute necessity of having an uniform pressure. From this cause, it appears that, although the

* Abstract of paper read before the Incorporated Gas Institute.

Digitized by Google

amount delivered could be measured approximately by meter, yet it did not always follow that a given amount registered produced the same amount of light, even with the same lamps in use. Again, a most important factor was met with in the instability of the secured custom of large consumers, owing to the facility with which a private installation can be put down, and, if worked with cheap gas power, the electricity produced on the spot at less cost. This was soon manifest, for already in Blackpool there are four private installations in operation having a working capacity of 200 units, or equal to the size of the central electricity works. So important does this question become, that immediately after the capital is expended the large customers are practically able to determine the price charged within very narrow limits to themselves, otherwise their custom, so essential to success, is lost, thereby entailing charges for unemployed plant, etc.

Electricity yields light or heat whenever a suitable resistance is offered to its passage, and this property is taken advantage of to obtain light in incandescent lamps. By means of raising a fine thread filament to incandescence (which can be accomplished by proportioning its thickness to the pressure and quantity of electricity passing through it), various degrees of light and heat are produced. The terms used to express these quantities in technical language are as follows:

Resistance.—The standard is called an "ohm," being the resistance offered by 129 yards of No. 16 copper wire.
Volt is the standard of pressure.
Ampere ,, ,, quantity.
Watt-hour ,, pressure × amperes × hours.
Unit ,, ,, kilowatt-hour, or 1,000 watt-hours.

As I have already mentioned, the production of light depends on the quantity and pressure being maintained. So much so is this the case that, taking an ordinary incandescent lamp placed on a town main, where the pressure should be maintained at 100 volts when the standard light given out is 16 candles, should there be any falling off in pressure, the light diminishes at about seven times the rate of the drop. Thus, should the pressure fall (say) to 96 volts, the light given will be reduced to about 12 candles; and if the pressure rises above 100 volts, the opposite is the case. Then, again, the life of a lamp varies with the change of pressure as follows:

Standard at 96 volts, 2,700 hours' life, yields 12 c.p. nominal.
,, 100 ,, 1,000 ,, ,, 16 ,,
,, 105 ,, 300 ,, ,, 20 ,,

Throughout the nominal life of a lamp the light gradually diminishes; so that the real effective life is much less for lighting, if we assume a lamp to be used up when the light drops from 16 c.p. to 14 c.p. The result of this to a consumer is that, although he may pay for a certain quantity of electricity, there are many considerations before he gets his equivalent in light.

The method of charging for light affords a similar analogy to that of gas where the consumer, buying light, is supplied with a unit of gas, called 100 cubic feet—costing 3d. at Blackpool—which will yield him, when burnt in a standard burner, 3·6 sperm candle-power per hour from each cubic foot used. In burning gas, however, the result depends on a minimum pressure being used, and this is under control at each burner—the pressure in the mains being kept slightly in excess of actual requirements in consequence. Although electricity is not sold in cubic feet, yet it fortunately so happens that the unit by which it is measured yields nearly the equivalent in light of 100ft. of gas, so that for purposes of comparison of cost a unit of electricity and 100ft. of gas approximately correspond. Electricity, then, is charged by the unit, and this is equivalent to the quantity of electrical energy supplied in one hour by a current =one ampere, which, multiplied by the pressure, yields 1,000 watt-hours, and is commonly called a kilowatt-hour. Applying this rule to lighting, it is known that an ordinary long-life incandescent lamp takes four watts per candle for each hour used, but there are short-lifed ones that can be had, taking 3 or 2½ watts per hour only. The best lamp to use is a matter for experts to decide; for, owing to the fluctuation in pressure on town mains, the rapid diminution of luminosity at different pressures, and other causes, it involves almost a mathematical calculation suitable only to electricians. Until we get a lamp that will maintain a standard light, there are other costs incurred besides those for current, just as there are in some forms of gas-burner. For outside lighting and large spaces with arc lamps, these remarks do not apply; as for this purpose, I think electricity has no rival in the field. These, then, are a few of the results found to be inseparable from an electrical supply; and when it is known that it is a physical impossibility to maintain an even pressure on all the mains, it will be patent that these are no little obstacles to be overcome as soon as the electrical company have emerged from the embryo condition in which most works are now placed.

As to the relative direct values of the cost of lighting, irrespective of the little shortcomings of both systems, the following is an approximate estimate of the cost of maintaining a 16-c.p. light by gas and electricity at Blackpool. For 1,000 hours per annum under all conditions:

BLACKPOOL GAS.—Standard Value, 18 c.p., charged at 3d. per unit, or 100 cubic feet.

Burner used.	Candles per foot.	Cost of 1,000 hours.	Add maintenance.	Total.
Argand	3·6	11s. 0d.	1s. 0d.	12s. 0d.
Special	3·0	13 3	0 6	13 9
Common	2·5	16 0	0 3	16 3
Bad	2·0	20 0	—	20 0
Regenerating ...	10·0	4 0	Not	known.
Welsbach	20·0	2 0	Not	known.

BLACKPOOL ELECTRICAL SUPPLY.—Standard Incandescent Lamp, 16 c.p., charged at 6d. per unit.

Incandescent lamps, watts per candle	Watts 16 c.p.	Life of lamp (estimated).	Cost of 1,000 hours.	Maintenance.	Total.
4	64	1,000	32s. 0d.	1s. 6d.	33s. 6d.
3½	56	750	28 0	2 0	30 0
3	48	500	24 0	3 0	27 0
2½	40	—	20 0	Not	known.
2	32	—	16 0	Not	known.

These tables are necessarily founded on estimated cost, and are only to be taken inferentially—actual tests not having been made under ordinary working conditions. After reviewing all the foregoing facts, it is palpable that electricity as a lighting agent has a certain commercial value, and given the possibility of sufficient support at the commencement of the undertaking, there is no reason why this agent should not be utilised to general advantage. This was the view taken at Blackpool before starting the works. I should here mention that still further confidence was given by the Corporation having had an electrical station going for 13 years previously, so that they had some knowledge of their own of its capabilities. In this works of an older type electricity used to be produced at 3d. per unit, and on a larger scale, with modern plant, it was expected a less figure would be reached. During the periods between these years various estimates were got out for a general scheme; and, as showing how unnecessary caution had perhaps been used, it was always assumed that a constant supply would be required, and under the knowledge at that time obtainable it was considered impossible from economical grounds. Eventually, after seeing the working in other towns, this was ignored, and we started to supply from dusk till midnight, which is now increased to an 18 hours' supply out of 24, although a compulsory supply can be demanded constantly. It is owing to the electric companies not always fulfilling their obligations that a good deal of preliminary success is attributable. Concluding these remarks on the subject, I will take the opportunity to describe the manufacturing plant of both agents, commencing with a description of the gas plant and following with that used for the supply of electricity. As a result of the year's working gas is now reduced to 2s. 4d. per 1,000ft., with a free meter.

(To be continued.)

TRANSMISSION OF POWER FOR MINING PURPOSES

An interesting illustration of the application of diphase alternating currents has been carried out at the Decize coal-mines belonging to MM. Schneider and Co. The generating station is situated at distances of 3·1 miles and 1·86 miles respectively from the most distant parts of the mines supplied with electrical energy. It contains six boilers and two steam dynamos, each of 100 kilowatts, and a third unit of the same capacity will ultimately be laid down. The two sets already installed can be operated separately or in parallel. The engines, which run at 200 revolutions a minute, are of the horizontal non-condensing type, and drive the alternators by belting. Each set of generators comprises two machines, arranged one at each end of a shaft, the driving pulley being placed between the two. The alternators are of the Zipernowski six-pole type. The exciting current is furnished to each pair of alternators by a direct-current dynamo actuated by belting from

Digitized by Google

the shaft of the generators, the current required for the two alternators being from 25 to 30 amperes at 110 volts. The magnet coils of the alternators revolve, whilst the armature is fixed. The conductors, which are mostly carried overhead on poles 25ft. high, are of silicon bronze, and are supported on porcelain insulators. The diameters of the wires is 6mm. for the main line and 4mm. for the other. At intervals of 540 yards the wires are crossed so as to annul the effects of induction on the telephone wires carried at the middle of the same posts. In this connection it is interesting to note, according to an article in *L'Industrie Electrique*, that although the return of the telephone is formed by the earth, no difficulty has been experienced in the transmission and comprehension of speech. The end of the principal line and of the telephone wire towards the Chagnats pit alone are placed underground. In this case lead-covered cables laid in wooden conduits have been employed. Lightning protectors have been provided at different parts of the line and at all the stations. The electromotors used are of the same type as the generators, with the exception that they have twice the number of poles. One motor of 30 h.p. is installed at the Fendue des Lacets, and a second of the same power at the puits des Coupes. A third motor is now being put down at the Chagnats pit. It is noteworthy that these motors are practically left to themselves, an attendant making an inspection every six or eight hours. The substations in which these motors are installed are situated in the forest, and the only indication of the presence of the motors is the hum caused by the ventilating fans which they drive. In addition to these motors there are two others which respectively operate hauling machinery and pumps, whilst at the same time some 24 arc lamps and 600 incandescents are lighted from the same generating plant.

THE GLASGOW CORPORATION ELECTRIC LIGHT STATION.

In our issue of May 18 was published an abstract of the paper read by Mr. William Arnot, A.M.I.C.E., before the Institution of Engineers and Shipbuilders in Scotland on "The Corporation Electric Light Supply." We also gave a report of the discussion, which has since been completed and printed in the *Transactions* of the institution. The resumed discussion is as follows:

Mr. M'Whirter said he must congratulate the institution on the paper put before them by Mr. Arnot. It had thrown a great deal of light on the installation of electric lighting in Glasgow. Mr. Arnot had given sufficient information to those who were able to follow the paper to desire more light. Some parts of it were very clear, but the very parts—speaking for himself—that he was most in the dark about were the parts that were not so fully explained as they might have been. He trusted that Mr. Arnot, in his reply to the discussion, would make a large addition to what he had already put before them. Mr. Mavor differed very strongly with the Glasgow Corporation for the system of electric lighting they had adopted. That was only to be expected. He was satisfied that they had so far adopted the right system, but he could not see how it was they adopted the absurd voltage of 200. Certainly it would have been much better had they adopted 220 or 230 volts. There would have been a gain of 10 or 12 per cent. in the distribution of current, and there would also have been a very great gain in the working of arc lamps from the system of electric lighting. It was a well-known facts that 100 volts was altogether too neat for working the arc lamps that they had at their command at the present time, but even 100 volts could not always be got. He found the voltage recently to vary more than four volts, so that when they took that off it was quite sufficient to cause the lamps to feed when they really ought not to have done so. He thought it a very great pity, indeed, that 100 volts should have been adopted. That was 200 volts between the outside mains. On the question of efficiency he had no doubt at all the Glasgow installation showed very well, a compound efficiency between the engine and dynamo of 88 per cent. commercial, and 17·5lb. of water per horse-power, which was all that one could desire. They could point to very few cases of the transformation of energy where anything approaching this was done. If they had adopted the alternating system, he did not think they would have got an efficiency exceeding 66 per cent., or something like that, so that here there was a clear gain of 20 per cent. in conversion. There might be, however, as was mentioned by Mr. Mavor at the last meeting, a considerable loss in the distribution as compared with the alternating system. Coming down to the question of accumulators, he could not say that he approved of the adoption of these in their present capacity in Glasgow. They were only able to carry on the lighting for a very short period of the 24 hours. He did not happen to know what the cost of these cells was, but he thought it would reach something like £2,000, and if they took that £2,000 at 13 per cent., which he thought would soon be required, although they were told by the makers and others at present that the maintenance charges was practically nil, yet those who have had accumulators know that 13 per cent. is nearer the cost of maintenance than anything under it. (**Mr. Mavor**: 30 per cent. is nearer it.) He had no doubt at all that the introduction of accumulators in this system was done with the view of saving money, but if they took £260 he was quite certain it would do more than fill up the interval over which the accumulators carried on the lighting by direct working. Of course, there was another thing to add to that. From the accumulators not more than 85 per cent. efficiency was got, so there was another 15 per cent. gone there. Mr. Arnot called attention to a system of keeping the cells in good order, where he said: "There are six cells as repair cells, or, as they are sometimes called, milkers. From these plates are taken to replace faulty ones in the working set, and should a cell show any weakness it is not allowed to discharge for a day, but is short-circuited by two milkers in series. It has thus four volts across it." He was assuming that the faulty cell had got a back E.M.F. of 2½ volts. That was, they had 1½ volts tending to send a current through that cell. Assuming for the sake of argument that the resistance of the cell was only ·001, or something less than that, it appeared to him they would have something like 1,500 amperes going into the faulty cell. Perhaps there was some other arrangement, and, if so, they would be glad to know something about it. About the underground mains Mr. Arnot did not say very much. Mr. Arnot said nothing about the insulation of those mains, but perhaps he would kindly give them that. Speaking as a telegraph engineer, he never saw such an attempt at insulation as in Glasgow. He did not think the resistance in ohms exceeded three figures. That being so, there was something going on continually that some day would be very serious. Supposing the resistance were taken at 300 ohms, that would mean, with 200 volts, an ampere of current loss. If they had an ampere of current going to waste, it meant 18 grains of copper being removed from the positive conductor every hour, or something like an ounce of copper per day. How long was that going to continue before there was anything very serious? The installation of the underground mains was very far from what it might have been. Mr. Arnot gave them very little information about feeders. The system of feeders enabled the potential to be kept constant all over the system. There were several ways that could be done. It could be done by connecting a dynamo between every pair of feeders. If that was done, unless there were a number of places where the amount of current carried by the feeders was identical, and the resistances were identical so that the potential at these places should be the same, then one dynamo must be run for each pair of feeders. Another way was to introduce resistance into the feeders, which meant loss. A better way, and a purpose for which he thought accumulators were admirably adapted, was to bring about this regulation by the use of accumulators, inserting, withdrawing, or reversing as required. This last was economical, and did the work exceedingly well. Mr. Arnot stated that they had decided in Glasgow to paint the negative red, and he gave them his reason that it was because there was a paper used for pole finding, which, when touched by the negative pole or wire, there was a red mark produced. He had been looking into that, and had a lot of papers giving red, blue, brown, or green, and it was difficult to see why an installation like Glasgow should have changed what had been use and wont for many years—*i.e.*, the positive conductor had always been painted red since ever there were any distinguishing marks used, so why it should be changed and the negative made red, the actual reverse, for such a simple thing as the colour produced by a pole-finding paper, was something beyond his knowledge. He thought, when they had a system which had been carried out practically all over the world, that there should be some solid ground to bring about such a change. There was another interesting matter which Mr. Biggart brought up at the last discussion. That was the question of cost. Unfortunately, Mr. Arnot had not run the station a year, and until that time they could not get it, but they hoped to get it in another paper, and he might then let them know the profits the Corporation were making. The present charge, he believed, was 7d. per unit, or, if compared with gas, it was something like gas at 7s. per 1,000ft. That meant that those who used electric lighting must consider it a luxury, but, of course, there were certain benefits which reduced this price. For example, there was less painting and cleaning, and the lights were not required to be always burning, and when these things were taken into account and compared with gas it was something like at the rate of 5s. per 1,000 cubic feet. When they kept in mind that there was a company in Newcastle supplying electricity at 4½d. per unit, and paying a dividend of about 5 per cent., and who had actually been paying a dividend over the whole period of their existence at the rate of 4 per cent., there was certainly something that the Electrical Committee of the city of Glasgow required looking into, and in support of that, in Bradford, where the conditions were almost identical to what they were in Glasgow, the cost of production was only 2·57d. per unit; and in Glasgow, without going to Bradford or Newcastle, there were many instances where gas-engines were supplying a unit of electrical energy with a consumption of 30ft. of gas, or, say, 1d. per unit, so that there was something wrong with the system, or the public of Glasgow were being very much overcharged—perhaps a little of both. He certainly could not see that there was any inducement to anyone requiring much lighting to take power from the Corporation mains so long as the price was anything approaching the amount being charged now, when they could get a gas-engine to

Digitized by Google

give them the same at much less cost. They knew how little attention a gas-engine required, and the cost of the engine, interest, and depreciation was easily ascertained, and added to the penny per hour would certainly make a very small item.

Mr. H. A. Mavor said that since last meeting he had come to the conclusion that a discussion of this sort was not long enough to enter into the whole question, and he would confine himself to the discussion of the station as it stood, and perhaps his other remarks might be embodied in a paper which he might read next session. In the discussion at last meeting he stated that he might look forward to engines of 10,000 h.p. being used. He was trusting to his recollection for figures. Ten thousand horse-power was about the size of a generating station suitable for one district of Glasgow, so that, of course, the individual engines would be much smaller. Coming now to the station as it stood in Waterloo-street, the first striking difficulty that appeared to one was what led the Corporation and its engineers to place the station there. Every ounce of coal had got to be carted to the place; there was no water available for the condensers; the ground was dear, and it was by no means in the centre of the district which was to be supplied. The next peculiarity was the size of the unit—that was to say, the size of the individual dynamos that were laid down for the work. The station had about 1,862 h.p., and it was proposed to increase this to about 3,000 h.p. Mr. Arnot had shown that engines of the type used would run economically at half load, so that there was no economy in having engines in a smaller ratio of relative size than ½, that was to say, that when the smaller engine was fully loaded up, No 2 might start to run efficiently where No. 1 left off. Examining the existing plant on this basis, it would be found (the balancing dynamos being left out of account because of their adaptability for very light loads) that the second existing plant bore a ratio to the third of $\frac{1}{1.5}$, and the second to the largest of $\frac{1}{1.5}$, which would be quite a fair ratio. Therefore, all the arrangement of intermediate sizes, and the resulting complication of steam-pipes, wires, switches, etc, was unnecessary. The arrangement of the station for 3,000 lights on the lines which Mr. Arnot's paper clearly proved might have been adopted with perfect economy, should stand as follows: Taking the balancing dynamos and engines as they stood, the second engine would have been 300 h.p. instead of 160 h.p., as it was now. The third engine would be double that size, or about 600 h.p. To double that engine would lead to another difficulty. It was advisable in a lighting station to so arrange that the breakdown of any one plant should not interrupt the efficient working. It might be assumed that if a station was well designed, and the engines were working easily at their full normal load, it would be a safe thing to overload these engines by 30 per cent. In fact, for a short time a good dynamo might be worked at double its normal load, as might be seen from the load curves. The time of the full load was only a quarter of an hour during the whole year, and therefore the risk of having to run the plant 30 per cent. overloaded for a quarter of an hour was not a serious risk. The size of the units would, by this consideration, be limited to about 700 h.p., and that might be taken, for the purpose of this argument, as the limit to the size of an engine in a station of 3,000 h.p. Argued out in that way, there would be for the 3,000 h.p. four large engines, one small one, and two little balancing engines, or seven engines in all of three different sizes. What had been done in the Glasgow Corporation station? There were 13 engines in the complete plan; the biggest one was 350 h.p., and the engine-room was like a toyshop. From the load curve on December 26, which was about the date of the heaviest curve in the year, it would be seen how rapidly the load runs up from about one-fourth of the output of the station right up to the top inside of an hour. Now the trouble that was involved in the starting of no less than 12 engines between the top and bottom of that load might be imagined, and it seemed a manifest absurdity that this trouble should be incurred. There were still three engines of 350 h.p. each proposed to go down, and he hoped the Corporation would be persuaded to put down as big engines as the place would hold, and abandon this duplication of ridiculously small units. Four years ago on a visit to New York he had occasion to call attention to what seemed to be a similar mistake which was being made by the Edison Illuminating Company. They were arranging a new station, which was now the Elm-street station, and they proposed to proceed with 600-h.p. units, which were just as small in proportion to the size of their works as the units here were—in fact, smaller. Very strong representations were made to them, and these were successful so far as to be an element in the considerations which induced that company to send their chief engineer to visit this country. He spent some time on this side, visiting London and the Continent, and when he went back he increased the size of the units—although, in the speaker's opinion, they were still too small, and before the station was complete probably the size of the later engines would be increased. For the Elm-street station as it stood it was proposed to use ten engines of 2,000 h.p. each. Returning to Waterloo street, there was no necessity for having any main engine smaller than 630 h.p., but as a concession to risk of breakdown one of 360 h.p might be admitted. A great delusion in possession of the minds of many electrical engineers was that it was necessary, even at large capital cost, to save the last ounce of coal in a generating station. It was good to work economically, but it must not be done at too great a cost. Probably it was with a view to economy that so small units were used, but it was carried to an absurd extreme. The cost of the station as it now stood had been, he estimated, from £2,500 to £3,000 more than it would have been if engines of the size spoken of had been put in. It was difficult to see what argument could be found for the use of such small units, unless it were what must be, after all, a fairly strong argument, that the biggest engine in the Glasgow station was the biggest engine of the type which had been manufactured at that time by Willans and Co.; that might have been fair excuse in the circumstances under which the Glasgow Corporation were placed. They had to get quick delivery of the engines, and were obliged to buy them from a maker who could take the pieces out of stock. Willans and Co. were able to do this. Looking to the large area still to be lighted, he thought it would only be fair to ask the Corporation to begin their arrangements in time to enable them to ask Clyde engineers to offer for the next engines, and give them time to make them. On the question of storage batteries, he had tabulated a debtor and creditor account, with blanks for Mr. Arnot to fill up, and he hoped he would do so. There was on the debit side: sinking fund or cost, rent or charge for space, attendance, repairs and upkeep, loss of energy in difference between charge and discharge at 1d. per unit. On the credit side: coal and attendance saved. He thought that although it would be interesting to have those figures, it was perhaps hardly fair to ask for them, because the money would probably be all on the one side. He did not think anything could be shown for storage batteries on the credit side of the account. It was no doubt a great help to the engineer to have storage, because it enabled him to shut down and make repairs on steam-pipes, etc., and upon this no definite money value could be put; but he maintained that that could be as well done in the Glasgow station by having a 100-h p. gas-engine, or a turbine driven by water power from the hydraulic mains at high pressure, either of which would be as convenient as a storage battery. He had the pleasure of seeing in Antwerp such an hydraulic arrangement, and nothing could be more simple, and probably the cost would be much less than that of storage batteries. He did not think it would be fair to charge the Glasgow Corporation with all the unfortunate difficulties that Mr. M'Whirter had referred to as having taken place in the underground mains. Still, he could not help thinking that the system of iron culverts and bare wires, would, even with the best workmanship, be unsatisfactory; and, in view of the probability of putting the middle wire to earth, this method was almost certain to be abandoned in favour of some more trustworthy and safe system of running underground wires.

Mr. Mavor said he was anxious that his arguments on large engines should have some effect, and, therefore, that they should not be misunderstood. He did not propose that the station should be run by two engines. It would be quite clear that his argument had two elements—first, that there is no economy in having in an engine less than twice the size of its predecessor; and, second, that the size of the engine is limited to one-fourth of the total output of the station. With these two arrangements they had provision for economy and provision against breakdowns.

Mr. Sam Mavor said he thought the wisdom of the choice of engines was open to question. Engines of this type had certainly given very satisfactory results in the matter of economy, but the records of their use for central-station purposes extended over a comparatively short period. The conditions experienced by electric lighting engines on board ship were often exceptionally severe, but the fact was that double-acting engines by many well-known makers had successfully withstood these conditions, while engines of the type in question had succumbed. The faults which developed rapidly under severe conditions would probably also develop in longer time under more favourable conditions. His own experience of the Willans engine in the smaller sizes had been extremely satisfactory; but he believed that central-station engines of the marine type, of which there were so many examples at work on the Continent at speeds of about 120 revolutions per minute, would still be doing hard work after the engines in the Glasgow central station were used up. With regard to the battery, he failed to see why a battery should have been used in Waterloo-street, especially bearing in mind the fact that the arc lamp plant was also put in Waterloo-street. The primary use of the battery in such a case appeared to be to allow the boilers to be shut down and to save a shift of men, but in Waterloo-street there was the necessity for it to be run every night and all night. The battery certainly was a decided convenience in switching the load off and on when adding on or taking off a dynamo, but the cost and complication seemed to be quite unwarranted by the very slight gain which it could show in this case. With regard to the mains, if Mr. Arnot had not too much to reply to, he would like if he would, in giving the information as the mains, give them the insulation of each wire. He had heard from some of the other three-wire stations that they found a difficulty with the negative conductor. The negative wire was said to go to earth, but that if the wires were changed round and the negative made the positive and the positive made the negative wire, the wire which was positive would go to earth and the negative come up. Mr. Arnot might give the result of his experience with regard to this phenomenon. With regard to Mr. M'Whirter's remarks about producing electricity by a gas-engine, it was rather absurd to say that a man having 100 lights would be better to have a gas-engine of his own. It was a matter of the number of hours during which these lamps were used. If he had a 100 lamps and wished to use them for a 100 hours per annum only, he had to spread his £300 over the 100 hours, and the cost would be out of proportion when the number of hours each lamp was in use came to 600 hours per annum. Then it came to be a question of whether it was cheaper to use a gas-engine for generating on the premises, or taking a supply from the Corporation, and herein lay a very important question which the Corporation would have to face. It meant that those consumers who used the lamps for over 600 hours per annum were the best-paying customers, and unless the Corporation would bring down the price below 7d. per unit the Corporation would lose those customers. It is also meant that in a large warehouse consumers would put down plants sufficient to do the portion of lighting which it would

Digitized by Google

pay them to do, and they thus not only deprived the Corporation of all the paying portion of the lighting, but they switched on to the Corporation mains the portion which it would not pay them to do, and certainly would not pay the Corporation.

Mr. Rankin Kennedy, in a written contribution, stated that he thought the site chosen for the generating station most unsuitable. It should be a first requisite in choosing a site that it be either on a railway siding, on a river bank or canal, for convenience of carriage. He also thought that the system adopted was not the best for a city like Glasgow. It was contended that it was the best for the area for which it was designed; that, however, was a moot point, but was not now worth discussing. The low-pressure continuous-current system adopted could not in the future be extended to other parts of the city, and even if it could the site chosen was not fit for a larger station. That the low-presure continuous-current system was unfit for extensive supply was admitted practically by the designer of the Glasgow station—was proved by the fact that he had advised a mixed system for Edinburgh—a combined continuous-current and alternating-current system. The remarks of Mr. Mavor in regard to the steam-engines used he fully endorsed. In the United States the necessity for large well-designed engines was now recognised, and on the Continent of Europe large marine engines were now adopted. In London, and in some other places, the electric lighting was in the hands of companies: in Glasgow, and other places, it was in the hands of corporations. This fact made a difference apparent to any engineer who could make an estimate of the value of machinery and electrical plant. The corporation plants were pretty much stereotyped copies of one another, and ran up to a large initial cost per lamp capacity. The companies seemed to get much more for their outlay. As the paper was a descriptive one only, it could not afford much room for discussion. The practice at the station was quite orthodox, and might be expected to give the usual results common with such well-known machinery, and some few years must elapse before it could be criticised on actual results of its working. The proposal to put down similar stations when electricity was required in other districts, was not likely ever to be put in practice; by the time these were necessary it was to be hoped that better counsel would prevail. The large central station, like the gasworks, was the station of the future, distributing at high pressure to the various districts.

Prof. Jamieson said the first thing that attracted attention in Mr. Arnot's paper was the want of uniformity in describing the plant. For example, he mentioned the names of the makers of such simple matters as steam-pumps and feed-water heaters, but omitted the names of those who had constructed the boilers, dynamos, etc. Moreover, he had given but a very imperfect idea of the general arrangement of the central station. If the statements regarding the number and sizes of the engines employed had been neatly tabulated, they should have been better able to follow Mr. Henry Mavor in his remarks about the size of the units employed, to which he took such vigorous exception. Both the wall diagram and one of the figures showing the "switchboard" connections were so unconventional and complicated that he was certain very few of those present would take the trouble to try and comprehend them. He had therefore prepared what might be termed an "educational diagram." When this was compared with its corresponding "index to parts," there would be no difficulty in grasping the leading principle of the whole arrangement. The great advantage of depicting complicated electrical connections in this way was very apparent. Mr. Arnot had given a minimum amount of information regarding the insulation and general behaviour of the main conductors and their feeders. They should like to learn from him (1) what was the lowest safe working insulation resistance of the whole system at any particular time? (2) what proportion of the whole current was lost by leakage in the mains? (3) what was the proportion of the power generated to that paid for by consumers? He mentioned an interesting and novel method of fault-finding without informing them who devised the same, or how near a fault could be "spotted" thereby as compared with other methods. His remarks on this subject would have been better understood if they had been accompanied by a diagram. He (Prof. Jamieson) held very different views from those expressed by Mr. Henry Mavor in regard to the size of the units into which a central station should be divided. In the first place, the greatest economy resulted when engines and dynamos were worked at full load. Consequently, it was most advisable to be able to increase or reduce the amount of the plant in action at any time, so as to correspond as nearly as possible with the public demand for current. If the central station contained but two large slow-speed engines and alternators, each capable of bearing the maximum load, they should not only have a needlessly large percentage of spare plant, but the working of the machinery would be at a very low average output, and consequently at a low efficiency. Further, it was preferable to adopt high-speed direct-coupled engines to slow-speed belted engines; for, if the latter were employed, they must synchronise not only the alternators but also the engines. The extension of the Glasgow central station could be best carried out by placing suitable gas-engines and dynamos at several points on the circumference of the system. Whenever those in charge at these outlying sub stations observed the pressure falling below the normal, they could start their plants in a minimum of time, and thus help the central station to meet the demand. Mr. Biggart had asked a very pertinent question—viz., what was the relative cost of gas and electric lighting? He was of the opinion that Mr. M'Whirter's reply to this question was too favourable to the latter. For, with Glasgow gas at 2s. 6d. per 1,000 cubic feet, and electricity at 7d. per Board of Trade unit, it only required simple proportion to prove that candle for candle they were being charged at the rate of 9s. 5d. per 1,000 cubic feet of gas for their electric light.* But is the supply of electric light at this price paying the Corporation? Suppose that the whole capital hitherto expended by the Corporation amounted to £120,000. They paid 3 per cent. for the loan of this money, and 7 per cent. could not be said to be too much for depreciation, so that they had 10 per cent. of the £120,000 to lay past annually as a first charge. Now, their income from the supply of current for public and private lighting certainly did not amount to more than £15,000, thus leaving less than £3,000 per annum to pay the staff and run the two stations. Consequently, if they were not making a profit at 7d. per Board of Trade unit, they must wait a little before clamouring for a reduction.

Mr. Arnot said he had to thank them for the very appreciable way in which they had received the paper which he had the privilege to read. Replying, he said, Mr. M'Whirter asked the question: why adopt the 200-volt pressure? The reason that pressure was adopted was the circumstance that 5,000 lamps were already being supplied at 100 volts. The Corporation had to maintain that supply, and if they had altered the voltage they would have had to supply lamp renewals to these customers. Reference was made to a case in which the voltage was low in a certain part of the town. The reason of that, he said, was due to the works which are being carried out in Argyle street by the Caledonian Railway. The feeder could not be laid as intended. As a consequence the distributing main had to be increased, and acted as a feeder for a time; the rise and fall in the voltage was due to this cause, as the potential of 100 was kept constant at the far end of the distributing main. The feeder had now been completed. There was a case lately at one part of the town where a consumer complained of the voltage being low. When enquired into, it was found at that particular spot the balance was not right. The connection was made on the other side, the balance restored, and all cause of complaint removed. Why was the negative painted red? He did not make the negative red, nor did he suggest the negative to be made red. It was red in London before it came here. It was a matter of no importance whether it was red, green, or scarlet. The consulting engineer brought it to Glasgow; that was how it was adopted. Referring to the feeders, he said they were not regulated by different rheostats nor by separate dynamos on each feeder. A single dynamo could be put on any individual feeder. It had never been found necessary to raise the potential of any of the feeders above the others. All had been run from the common omnibus bar. The copper resistance of the feeders was calculated and adjusted to a certain load. The network for the distribution being continuous throughout a city, he found the load equalised itself, and the potential was quite easily maintained constant at the different feeding points. He had not found the difficulties spoken of, and he was quite confident that when the difficulties did come the staff would be able to cope with them. The insulation of the main was an important matter. On Sunday afternoon, at 3 o'clock, he measured the outgoing current on a Kelvin balance. He sent the current out on one feeder, disconnecting all the others; the readings were—on the positive, 8 amperes, on the negative side, 17·9 amperes. He knew there were lights in the post office, in a number of jeweller's shops, and other places, they burned a pilot light constantly, and there were lights in the kitchens and underground offices of such places as clubs, and in the lighting stations there were a few lights. On that same Sunday the insulation resistance of the street mains, with all the work on consumers' premises attached—it was found that few broke their main switch—on the positive side was 860 ohms to earth; the middle wire was 710 ohms to earth, and the negative side was 70 ohms. It was the case that the negative side got gradually lower, but it was not a dead earth. On connecting a very low-resistance ampere gauge between the positive wire and earth the current was to-day 1·5 amperes. Referring to Prof. Jamieson's remarks on the switchboard, he said perhaps there were too many connections and too many wires shown, but he purposely did that that they might have a correct drawing in the *Transactions* that they could study at their leisure, and if it was not understood now it would be at a future date.

The **President** said Mr. Arnot had given a very important paper, and the discussion had been very interesting. This year a great variety of subjects had been read before the institution, and which a number of them were not able to discuss. Such a scheme as that was still in its infancy, and if it had been extended on the whole to this year it might not have been too late to remedy the mistake the Corporation had already committed. He hoped every magistrate and town councillor would obtain a copy of the *Transactions* of the meetings which have been held, and in the future extension of that system that the discussion should take place here before it was two late—perhaps before the work was commenced—and specifications and plans be brought before them here, so that they would be able to give the Town Council authorities a decision as to how they were to proceed. He proposed that the institution should give Mr. Arnot a hearty vote of thanks for his paper. Mr. Andrew Wilson was to have exhibited a model of an apparatus for lessening the rolling motion of seagoing vessels, but as it was too late it would require to be postponed to the next session.

---

* For, 5 cubic feet of gas per hour gives a light of 20 c.p., ∴ they had $1,000 \div 5 = 200$ hours of lighting for each 20-c.p. burner, or 200 hours $\times$ 20 c.p. = 4,000 candle hours for 30d. But an average 16-c.p. Ediswan electric lamp requires 65 watts ∴ 1,000 watt-hours, or one Board of Trade unit, will light 15·4 lamps for one hour. Or, $15{\cdot}4 \times 16 = 246{\cdot}4$ candle hours for 7d. ∴ if x = equivalent price of gas per 1,000 cubic feet, we have, by proportion, $246{\cdot}4 : 4{,}000 :: 7 : x$, ∴ $x = 28{,}000 \div 246 = 113$d. = 9s. 5d. Or, the present cost of the electric light in Glasgow is 3·76 times the price of gas at 2s. 6d. per 1,000 cubic feet.

THE HISTORY OF WOODHOUSE AND RAWSON UNITED, LIMITED,

As Detailed in the Bankruptcy Court.

MONDAY.

The public examination of the directors and officers of Woodhouse and Rawson, United, Limited, was commenced on Monday before Mr. Registrar Hood, at Bankruptcy-buildings, Carey-street. The Company was registered in July, 1889, the signatories to the memorandum and articles of association being Lord Aberdare, Mr. Philip Rawson, Sir Thomas H. Farrer, Sir John Stokes, K.C.B., Sir Albert J. Leppoc Cappel, K.C.I.E., Colonel C. E. Howard Vincent, C.B., M.P., Sir John Coode, K.C.M.G., and Mr. F. L. Rawson. The Official Receiver in his observations upon the case states that the Company was formed for the primary purpose of amalgamating the businesses of Woodhouse and Rawson, Limited, electrical engineers, and other companies. The gross liabilities are returned in the accounts at £212,628, of which £14,713 are expected to rank, with estimated total assets £211,772, subject to claims of debenture-holders £166,482, and to preferential debts £940, resulting in an estimated surplus of £29,626. The deficiency as regards contributories is £448,321. The Official Receiver states, however, that the receiver for debenture-holders does not concur in the value of the assets given in the accounts, his opinion apparently being that it is doubtful whether they will realise sufficient to pay off all the claims of the debenture-holders. It appears that Mr. F. L. Rawson has furnished a detailed statement as to the causes which have led to the Company's insolvency. Briefly given, these are (1) that the industrial portion of the business was, during the earlier stages of the Company's history, "unduly pushed under inadequate supervision," and (2) that heavy losses were incurred as a result of the litigation between the Company and the Edison-Swan United Electric Lighting Company, and also by reason of the general depression in trade and finance, necessitating the curtailment of some portions of the Company's business, and that, while these difficulties were in course of being overcome, the Company's operations were brought to a standstill by the action of a consultative committee appointed in December, 1892, whose report, presented after some delay, was absolutely destructive to the Company's credit and reputation.

Mr. C. J. Stewart attended as senior official receiver; Mr. Muir Mackenzie, Mr. H. T. Eve, Mr. J. A. Cartmell, Mr. C. E. Jenkins, Mr. Stirling, and Mr. Pilling for directors and others interested in the proceedings; and Mr. W. M'Kay (Ward, Perks, and Co.) for debenture-holders and also for the Official Receiver.

The **Official Receiver** stated that considerable delay had taken place in obtaining a sitting for public examination owing to the great difficulty experienced in ascertaining the facts and to the non-production of a large number of books and original documents, and he had not been able to obtain any satisfactory explanation with regard to them.

Sir John Stokes, K.C.B., was first called, and in reply to the Official Receiver stated that he was a director of Woodhouse and Rawson, Limited, and subsequently became the liquidator of that Company. The books were ordered to be destroyed by a resolution of the shareholders when the liquidation was closed in November last, the resolution being proposed by him as chairman. He had never heard it suggested that the books would be required under these proceedings. He could not say whether one of the minute-books had been destroyed or not, but he had not seen it since the close of the liquidation.

Mr. F. L. Rawson said he was aware that the books had been destroyed under the resolution mentioned, but he was not aware of the resolution being passed.

Sir Albert J. Leppoc Cappel, K.C.I.E., was next called, and, in reply to the Official Receiver, stated that he was one of the original directors of Woodhouse and Rawson United, Limited. He joined the Board at the request of Mr. F. L. Rawson, who represented to him that four excellent industrial undertakings were to be acquired, which, for reasons of general policy and economy and management, it was thought desirable to combine into one, and he was informed that the Company would make a good deal of money by "fostering" patents.

The **Official Receiver**: Which came first—the industrial branch or the "fostering" of patents?

Witness said it was undoubtedly an industrial undertaking. He believed that, with the exception of one small one, the companies acquired were carried on at a profit. Numerous meetings of the directors were held before the incorporation of the Company, when the whole matter was gone into, and he attended most of them. He was unable to recall at the present moment the enquiries which were made as to the various concerns to be acquired. He recollected seeing a valuation made by Mr. H. Edmunds in April, 1889, of the patents which were to be taken over, in which they were valued at £159,265. The prospectus which was subsequently issued set forth that the patents had been "valued by competent experts and the value placed upon them has been the guide in fixing the purchase-money."

The **Official Receiver**: Did you understand that the valuation referred to in the prospectus was an independent one?

Witness: I did.

The **Official Receiver**: Were you aware that the actual language of this valuation had been drafted by Mr. F. L. Rawson?

Witness: Certainly not.

The **Official Receiver**: I take it you would have looked with doubt—I will not say suspicion—upon the valuation if you had known that it was drafted by Mr. F. L. Rawson, he being practically the vendor?

Witness said that if he had possessed the knowledge he would have left the place then and there, and have had nothing to do with the Company. According to his recollection the Elmore patents were not included in that valuation, and he certainly was not aware that these patents were included in it at the sum of £120,000, thus reducing the value of the patents acquired from £159,000 to £39,000. The Company acquired the patents for £85,000, but if he had been fully acquainted with the facts, he would not have agreed to pay that amount for them. The purchase price paid for the businesses was £269,000, the goodwill being agreed at £97,000.

The **Official Receiver**: Why did you pay such a large sum for the goodwill?

Witness said he believed the undertaking was a successful industrial one with a valuable connection, which with good management and supervision would prove very remunerative. It was represented to him that the profits earned by Woodhouse and Rawson, Limited, for the year ending June 30, 1888, amounted to £21,440, and the profit for the succeeding year was estimated at £75,000. He learned after these figures had been published in the prospectus that they were somewhat qualified by a report of the accountant, which stated that the profits represented were partly made up by shares in other companies. To a certain extent that knowledge caused him to feel some doubt as to the accuracy of the statements in the prospectus. It now appeared that the balance-sheet for the year ending June 30, 1888, included about £35,982 in respect of shares in three companies. He could not say that he made a complete investigation into the businesses acquired. He had not had any previous experience in company matters, and as the whole of the negotiations were completed in about one month he considered they were very much "rushed." His feelings of uneasiness and anxiety gradually increased, and he became very determined about the Company going to allotment. He was not satisfied with the amount of applications received for shares and debentures. Immediately after the prospectus was issued he began to think there was a want of order and exactness in the manner in which the whole matter was conducted. At a Board meeting held on July 30, 1889, it was resolved by a majority of the directors that unless applications were received for at least £200,000 the money should be returned and they should not go to allotment.

The **Official Receiver**: Immediately that decision was arrived at I believe you were "fired at" by several legal gentlemen?

Witness said he received letters from several solicitors to the various businesses which were to be acquired, informing him that unless he agreed to go to allotment proceedings would be instituted against him for damages. There was a striking resemblance in the lawyers' letters, but he could not say whether they were the production of the same mind. After consulting his colleagues he resigned his seat on the Board, and a circular was sent round to the applicants for shares, stating the reason for his retirement, as well as that of Sir John Coode and Colonel Howard Vincent. It appeared from the circular that Sir Leopold M'Clintock, Sir Rawson W. Rawson, and Mr. Samuel Pope, Q.C., had consented to take their places; that further subscriptions for shares had been received, and that the allotment would be proceeded with. He stipulated that the circular should be sent out because he felt, if anybody had been attracted by his name to the concern, that they should have an opportunity of taking the course of withdrawing from it, which some actually did. The fact that he and his two colleagues who retired were the only three who were entirely independent of the vendor companies only came to his knowledge after they refused to go further into the matter.

By **Mr. F. L. Rawson**: He remembered several meetings taking place with reference to various matters connected with the business then in hand. Witness looked into the agreement in order to see that the best possible terms were obtained by the purchasing company. He took a great deal of trouble at the time, but could not tax his memory as to details. He was not in a position to say whether the Company paid considerably less for the patents than the amount at which they were actually valued.

By the **Registrar**: The directors obtained the advice of their solicitor respecting the patents, and upon questions of title.

Further examined by **Mr. Rawson, Witness** said that so far as he was aware there had been no refusal on the part of the Board to return the subscriptions of shareholders who had applied for the repayment of their application money in consequence of the circular announcing the retirement of three of the directors. The more he looked into the matter, the less he liked it.

Colonel Howard Vincent, C.B., M.P., was next examined by the Official Receiver. He stated that he consented to join the Board on July 19, 1889. He regarded the Company as an industrial and not as a financial undertaking. He soon became dissatisfied in consequence of the unbusinesslike manner in which the negotiations were conducted. No proper record of the meetings was kept, and difficulty was experienced in obtaining information. He knew that the firm of Woodhouse and Rawson was established in 1881.

The **Official Receiver**: Are you aware that the only transaction in which a profit was made to any extent was in respect of a "deal" in Elmore shares, when a sum of £78,000 was realised?

Witness said he was not aware of that fact.

By **Mr. Muir M'Kenzie**: The other provisional directors had taken pains to investigate the properties to be acquired. The negotiations, however, were unduly hurried, and sufficient time was not afforded for a full investigation.

Mr. F. L. Rawson said it had been alleged that he had made a profit in connection with the promotion of the Company, but he denied this, and asked the witness whether he knew it to be a fact.

Digitized by Google

Witness: I do not think that anyone has ever suggested that you worked for nothing.

Mr. Rawson: But I have never received a shilling in respect of promotion money.

Witness: Then I am very sorry for you.

TUESDAY.

The first witness called at the resumption of the proceedings on Tuesday was **Mr. Charles L. Baker**, who stated, in reply to the Official Receiver, that he formerly acted as managing director of C. L. Baker and Co., Limited, which was a company subsequently acquired by Woodhouse and Rawson United, Limited. About the beginning of 1889 he came to London on business and called upon Woodhouse and Rawson, Limited. Mr. F. L. Rawson approached him, and informed him that an amalgamation scheme was being considered, and asked if C. L. Baker and Co , Limited, would also amalgamate. The matter was shortly afterwards brought before the directors and shareholders of the last-mentioned company, and, it being pointed out that unless they agreed to the scheme their company would have to encounter very serious opposition, they agreed to the proposition. It was said that all the other companies concerned in the scheme were doing good business. He would not say that the directors of C. L. Baker and Co., Limited, understood that a large proportion of the proposed Company's business would consist of financial work or company promoting. It was known, however, that patents relating to electrical work would be "fostered." He was not aware of the sums to be paid for the other businesses acquired, but he knew that only an exceedingly small cash payment was to be made. C. L. Baker and Co., Limited, received in all £24,000 for their business, being as to £5,000 in cash, and £19,000 in preference shares, the amount for goodwill being £9,000, which was represented by *bonâ fide* profitable contracts. Independent valuations were made of the plant and stock, and he was of opinion that they were undervalued. He saw the prospectus before it was issued, in which it was stated that the profits of Woodhouse and Rawson, Limited, for the year ending June 30, 1888, amounted to £21,440. He was not aware, however, that the auditors submitted a report upon the assets which represented that profit in which they stated that "the accounts are in accordance with the books of the Company, but it is obviously impossible for us to be responsible for the net profit, owing to the nature of the assets and the Company's interest in many trading concerns." Mr. F. L. Rawson assured him that great care had been exercised in the preparation of the prospectus, and he understood that every statement contained in it was correct. He was subsequently informed that a difficulty had been raised about going to allotment, owing to three of the directors being dissatisfied with the amount of capital subscribed. He thereupon pointed out that if, from this cause, the Company did not go to allotment, most serious injury would be inflicted upon C. L. Baker and Co., Limited, as this company had specially stipulated that they should not be dangled before the public as a bait, and he therefore instructed his solicitor to acquaint the directors of the United Company with his intention to proceed against them for damages if they declined to go to allotment. From an interview he had with Sir Albert Cappel, he gathered that that gentleman had some doubt in his mind as to the success of the concern. He had also seen many adverse criticisms in the financial papers, but, knowing what they were, he did not take any notice of them. The Company, however, went to allotment, and witness was appointed general works manager at Cadby Hall, Kensington, and Cornbrook Telegraph Works, Manchester. He had had considerable experience in managing works of this kind, having been for a great number of years an electrical engineer. Shortly after the Company was started, he became aware that a sum of £85,000 had been paid for the patents acquired by the Company.

The **Official Receiver**: Did you form any opinion as to their value?

Witness said at the time he thought they might have been worth from £30,000 to £50,000, but now they were practically worthless, there being only one or two which were workable, but this was owing, to a great extent, to their being superseded by other inventions.

The **Official Receiver**: I believe the industrial branch of the Company's business has been a failure throughout its existence, has it not?

Witness said that very heavy losses had been incurred, but he attributed this to the fact that the business had been cut up and distributed, instead of being carried on under the management of one person. He did not think the losses in question amounted to £50,000. The foundry at Kidsgrove, Staffordshire, was purchased by the Company for £30,000, in shares. It was represented that the business carried on there was producing £8,000 a year profit, and, thinking that they were acting in the interest of the shareholders, the directors decided to acquire it. As a matter of fact, it had shown a considerable loss, and the directors estimated that the property had depreciated to the extent of £17,784 in July, 1892. When he entered upon his duties at Cadby Hall he experienced a considerable amount of difficulty in ascertaining anything about the concern, and to a great extent he was regarded as an interloper. Upon enquiry he discovered that affairs were in a very unsatisfactory condition, and upon his representing the same to the directors they expressed some surprise, and Sir John Stokes said he was disgusted with the state of things. In April, 1892, he sent a letter to each of the directors calling their attention to the position of matters, and suggesting certain alterations, but no action was taken upon it, and no mention of the matter was made to him. His only explanation of this was that the Board must have been engaged on more important business at the time. Ultimately he was unable to obtain funds for the purpose of carrying on the works, and a large proportion of the experienced hands were dismissed. In his opinion there had not been sufficient funds provided from the commencement, and difficulties had been experienced throughout. In the balance-sheet for 1891 there was an item of £3,425 included as an asset in respect of a "moiety of special expenditure on advertising, repayable by instalments." Witness took exception to this amount, and contended that it should not be included as an asset, but his objections were overruled. Shares to the value of £2,000 were given to him as his interest in C. L. Baker and Co., Limited, but at the date of the winding-up order he did not hold any of them, because he knew too much about the concern. He had realised from £3. 12s. down to 3s. 6d. for a £5 share. He had also purchased other shares in the Company when his faith in it increased, but these had also been disposed of.

In reply to **Mr. Muir Mackenzie**, the **Witness** said that when the business of C. L. Baker and Co., Limited, was transferred to the United Company he believed it was in a flourishing condition and capable of realising a large profit. When he joined the United Company he had every reason to believe that with good management it would have been a prosperous company.

Witness was also examined by **Mr. F. L. Rawson**, and stated that he had never heard it suggested that the latter had ever acted in a manner which was other than straightforward.

By a **Creditor**: At the time C. L. Baker and Co., Limited, was transferred it was a profitable concern, but it was impossible to say whether that particular branch had been so or not since the amalgamation, as the various businesses had been merged into one, as they could not be separated.

By **Mr. Pilling**: He considered that the business at Manchester was a larger one than that at Cadby Hall. A larger number of men were also employed at Manchester. The men at Cadby Hall were mostly boys.

Further examined by **Mr. Butcher**, **Witness** said that the directors of C. L. Baker and Co., Limited, were never anxious to amalgamate with the other companies, but, in view of the opposition which they would have had to face, it was considered advisable to do so. The names of responsible gentlemen appearing on the prospectus inspired him with confidence in the concern.

It was stated at this point of the enquiry that the minute-book of Woodhouse and Rawson, Limited, which it was supposed had been lost or destroyed had been found, and was at the disposal of the Official Receiver.

Mr. F. W. Pixley was next examined, and, in reply to the Official Receiver, stated that he had acted as auditor of Woodhouse and Rawson United, Limited, and of the Woodhouse and Rawson Electric Supply Company, Limited. Being on one occasion unable to obtain the necessary materials for the purpose of auditing the accounts of the latter company, his firm threatened to take further steps in the matter. That, however, might be looked upon as a figure of speech, because he was not aware of what further steps could be taken; it was a bark without a bite. He could not say whether that particular audit had ever been completed. In the prospectus of the Company it was stated that a profit of £21,000 had been made by Woodhouse and Rawson, Limited, in the previous year, but he did not certify to those profits—that was a matter which rested entirely with the directors. His certificate as auditor was accompanied by a report to the shareholders, and the certificate and the report ought to have been read together. In a book which he had written on the subject he expressed the opinion that the auditor's report ought to accompany the accounts which were issued to shareholders. He had since had occasion to modify that opinion owing to the difficulty of enforcing what he, as an auditor, might consider to be proper, and the book now quoted from was a very early edition of his work. The balance-sheet of October, 1890, exhibited a full and correct view of the Company's affairs, being founded upon the books of the Company. He even went beyond the books of the Company.

The **Official Receiver**; You were a "watch-dog" upon the directors?

Witness demurred to the term "watch-dog" as being altogether inappropriate. As auditor for the shareholders he considered it was his function to see that the transactions and accounts were as represented by the directors, and that there was nothing wrong about them at all, but he was in no sense a "watch-dog." As to the duty of an auditor, he might say that on one occasion he took upon himself to enlighten the shareholders, and the only acknowledgment he got for his trouble was his dismissal, because he was said to have exceeded his powers.

The **Official Receiver**: If you thought that it would be better for the shareholders not to know something, do you consider that you are justified in not telling them?

Witness: Yes, subject to certain qualifications.

Mr. Registrar Hood: What are they?

Witness said that there were numbers of trading companies now in existence in which it would be very disastrous for the public to know full particulars of their business transactions.

WEDNESDAY.

When the proceedings were resumed on Wednesday,

Mr. F. W. Pixley, an auditor of the Company, was recalled and further examined by the Official Receiver. He explained, with reference to his answers given on Tuesday, that he would not be acting rightly if he passed an account if there was anything in it which he knew was intended to mislead the shareholders of a company. He believed the shareholders of the United Company pur-

Digitized by Google

chased the concern thinking it to be a flourishing industrial business, and he was aware that considerable losses were incurred in that branch of the Company.

The **Official Receiver**: Looking at these circumstances, do you now think it would have been better to have disclosed the information you obtained?

Witness said he did. He distinctly warned the directors not to pay a dividend. Questioned as to the profit included in the balance-sheet at June 30, 1890, witness said a sum of £30,000 was included as profit in respect of the International Okonite Company, Limited, which was incorporated within a week of the close of the financial year. The cheque for that amount was held over for a week and witness insisted upon its appearing under the head of "cheques and cash in hand." He was not aware that the United Company subsequently applied for £40,000 of shares in the Okonite Company. Counsel's opinion was taken as to the right of the directors to include a sum of £17,000 as profit over the promotion of the West Kensington Stores, Limited, and they were advised that the sum could be included In a letter to the Company witness suggested that the trading and promotion accounts should be kept separate, but after several interviews with Mr. F. L. Rawson he did not insist upon the suggestion being carried out. He could not say that throughout the Company's existence he had found that Mr. F. L. Rawson was ever anxious to run the profits up higher than they should have been. Mr. Rawson was entitled to one-fourth of the profits after payment of a dividend of 15 per cent., and, according to the balance-sheet for 1890, he became entitled to £13,000, which was placed to his credit. In December, 1889, the Company declared an interim dividend of 15 per cent., and witness wrote protesting against its payment, it being very unusual for a dividend of that kind to be paid without the accounts having been drawn up and properly audited. He did not see any prospectus beyond the first, and he thought he had raised objections to his name appearing. He had never held a single share in the Company. He did not now think that he was wise in being persuaded to give way on the question of separate accounts for the commercial branch and the promotion of companies' business. According to the agreement made with the vendor company, a sum of £75,000 was to be deposited as a dividend guarantee fund until July, 1892, towards ensuring the payment of a minimum dividend of 15 per cent. for that period. In January, 1891, a meeting of the shareholders was held, when it was resolved to return the guarantee fund, a rebate of £12,000 on the purchase-money being allowed. Witness was not communicated with by the directors, but had his advice been asked he should certainly have thought it unwise under the circumstances to recommend this course to the shareholders. With reference to the balance-sheet of 1891, witness said that the gross profit amounted to £74,568. He had no reason to doubt the fact that a considerable loss had been made in the industrial business during the year's trading. The "profits" included an item of £14,975 represented as profit in connection with the Phœnix Trust Company, Limited. He became aware that this company was one promoted by Baron Grant and Mr. F. L. Rawson. Witness was not satisfied with the information given to him, and wrote a letter to the Board with reference to the way in which the profits were made up, in which was enclosed the certificate he proposed to give. The certificate was in the following form:

"We have examined the accounts of this Company for the 13 months ending July 31, 1891, and certify that although they are practically correct as regards figures, yet they do not disclose the following facts to the shareholders. The gross profit referred to consists almost entire of profits made on financial and not commercial operations, and is produced almost exclusively by taking credit for values put upon shares in other companies promoted by this Company, which are subject to realisation. The investments, consisting of £118,453, are composed exclusively of those shares and of those of a private financial company working in connection with this Company, while the shares in one of these companies, valued at £35,145, are only the property of this Company by virtue of an agreement signed on July 31, 1891. The 'sundry debtors' include an amount of over £15,000 due from the managing director. Nothing has been written off the patents or the patent rights and charged against the profit and loss. That in our opinion the guarantee to the shareholders having been renounced at a special meeting convened for the purpose, no dividend should be paid in money until the investments referred to have been converted into cash."

The **Official Receiver**: If that certificate had been appended to the balance-sheet would it not have acquainted the shareholders with the state of affairs?

Witness: It would have done so.

The **Official Receiver**: Why was it not appended?

Witness: Because it was represented to me that it would damage the Company.

The **Official Receiver** stated that important documents, which ought to have been in the possession of the Company, or handed to the Official Receiver, were missing. They must have been removed by someone. It was remarkable that several documents of importance had been "spirited away."

Mr. F. L. Rawson disclaimed all knowledge and responsibility in the matter.

Continuing, **Mr. Pixley** said that the issue of the above certificate would have had a prejudicial effect upon the interests of the Company.

The **Official Receiver**: You will admit that it would not be a ground for withholding the information?

Witness said it would not. The market value of the shares would have been damaged by the certificate. He yielded to the representations made to him, and, subject to certain pledges made by the directors, the certificate was withdrawn. He had several interviews with Mr. F. L. Rawson, and perhaps he was "over-persuaded" He wished it to be borne in mind, however, that the Company had a substantial reserve fund, The goodwill was taken in the balance-sheet at £98,000, and he held the view, in spite of the fact that the industrial business was carried on at a loss, that the Company were justified in keeping the goodwill at the same amount they had paid for it. "Sundry investments" were returned at £119,000, and the statement of affairs now showed a depreciation of £69,000 on the shares held. At the meeting of the shareholders no mention was made of the loss on the industrial business, and witness did not explain anything about his certificate. With reference to the balance-sheet of July, 1892, witness considered it his duty to make a special report to the shareholders in consequence of the books not having been balanced, and because certain items in the accounts did not afford in themselves a sufficient explanation of the position of affairs. He reported that it was impossible for him to complete the audit, as the books had not been kept properly, and that he was unable to vouch the payments in consequence of the vouchers not having been properly arranged and because certain of them were missing. The item, "sundry investments," £109,413, consisted of shares in companies either promoted by, or allied with, the United Company, and he asserted that he was unable to express any opinion as to their value. He also discovered that some of the certificates for the shares were not in the possession of the Company in consequence of their never having been issued. He reported that the loss for the year appeared to be £122,198, even supposing that the securities and the sundry debts (£73,612) realised the amount taken credit for, and that he was unable to accept any responsibility for the value placed upon the assets. Against this loss there was a reserve of £35,000, and a balance carried forward from the previous year of £8,030.

In reply to **Mr. Jenkins**, the **Witness** said that he had no reason to doubt the honesty and integrity of any member of the Board, but, in his opinion, the accounts were not sufficiently amplified.

By the **Official Receiver**: He was not aware that his predecessor in Woodhouse and Rawson, Limited, had resigned his position because he complained that he was interfered with in making an audit. It was the first time he had heard such a suggestion.

The enquiry was adjourned until Wednesday next.—*The Times.*

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the week ended June 15 were £2,379.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 17th inst. amounted to £882.

Wallsend.—Mr. W. Cathorne, the proprietor of a temporary theatre at Wallsend, proposes to erect a new permanent theatre to be lighted throughout by electricity.

West Ham.—As notified in our advertisement columns, the Council of the borough of West Ham invite tenders for the electric lighting of the public hall and free library.

Leeds.—Mr. Wilson Barrett will build a new theatre in Leeds which will be lighted by electricity. He has not yet settled upon a site, but the building is to be completed by April next.

Ayr.—The sub-committee of the Council who were empowered to select a proper site for electric light works, have been authorised to conclude negotiations without referring to the Council.

Accepted Tender.—The London County Council have accepted the tender of Messrs. Crossley Bros., Limited, for the supply and erection of three gas-engines at the Heathwall pumping station.

Walthamstow.—The Walthamstow Local Board have decided to take measures for the lighting of the district if the Lea Bridge Gas Company still decline to reduce the price they are charging.

Canvasser Wanted. — "British," of 50, Foregate-street, Worcester, requires a smart man, with a practical knowledge of electricity, for canvassing for wiring orders. Salary and commission are offered.

Dewsbury.—The Town Council have decided that the new chimney at the electric light station shall be octagonal, and of stone, at an additional cost, as compared with a brick one first proposed, of £100.

Dawson Gas-Engines Syndicate, Limited.—This Company has been registered with a capital of £70,000, in £10 shares, to acquire certain patents, the property of Henry T. Dawson, and to manufacture gas-engines.

Mansfield.—The tender of Messrs. Colomb and Co., London, for £123 for the erection of telephonic communication between the new waterworks and the manager's office, has been accepted by the Town Council.

Devonshire.—Application is to be made by the County Council to the Local Government Board for permission to borrow £8,000 in connection with the asylum, of which £6,000 is for the installation of the electric light.

South Staffordshire Tramways.—Mr. Justice Wright, sitting as an additional judge of the Chancery Division, last week dismissed the petition of Mr. Alfred Dawson and others for the winding up of this Company, the petitioners desiring to withdraw it.

Digitized by Google

Milford (Ireland).—The entire electrical plant at Milford, co. Carlow, has been sold by the representatives of Messrs. J. E. H. Gordon and Co. to Major Alexander, who is putting down a new alternator to meet the increasing demand for current.

Interest Warrants.—The City of London Electric Lighting Company, Limited, give notice that the transfer books of the debenture stock of this Company will be closed from the 23rd to the 30th inst. for the purpose of preparing the interest warrants.

F. H. Royce and Co., Limited.—This Company has been registered, with a capital of £30,500, to purchase the business of F. H. Royce and Co., at Cooke-street, Hulme, Manchester, and to carry on the business of manufacturing electricians and mechanical engineers.

Bradford.—Mr. John Hart has been having the Theatre Royal fitted throughout with the electric light. Power is supplied by two 16-h.p. gas-engines. The auditorium will be lighted with one large central electrolier, the dress-circle, balcony, and stage having separate lights.

Southport.—The annual report of the Highway Committee of the Town Council states that the gas used during the year for the engine pumping was booked 61,600 in 488¼ hours, averaging 126 cubic feet, but for charging the electric launch, etc., only 251 hours had been booked.

Paying of Coupons.—The Anglo-Portuguese Telephone Company, Limited, notify that coupons No. 13 of the first mortgage and No. 8 of the second mortgage debentures of the company will be paid by Parr's Banking Company and the Alliance Bank, Limited, on and after the 2nd prox.

Appointment Open.—The Vestry of St. John, Hampstead, are about to appoint an electrical engineer to take charge of their electric light station. He must have actual practical experience of alternating-current central-station work. Further particulars are given in our advertisement columns.

Presentation.—The employés of the firm of Messrs. Peto and Radford, of Hatton-garden, presented Mr. William Peto on Tuesday last with a handsome silver salver, engraved with a suitable inscription, on the occasion of his marriage on June 21 to Miss Woodhead, of Newlands, near Huddersfield.

Ship-Lighting.—The ferry steamer "Birkenhead," which has been built to the order of the Birkenhead Corporation by Messrs. John Scott and Co., of Kinghorn, Scotland, has taken her trial trip. A complete installation of electric lighting has been provided by Messrs. J. H. Holmes and Co., of Newcastle.

City and South London Railway.—The receipts of the Company for the week ended June 17 were £831, against £782 for the same period last year, or an increase of £49. The total receipts for the first half-year of 1894 show an increase of £719 compared with those for the corresponding period of 1893.

Wolverhampton.—The Town Council have authorised the Lighting Committee to advertise for tenders for the execution of the necessary works and the provision of all fittings for the supply of electricity to the Town Hall, market hall, art gallery, and free library, and to submit the same to the Council for acceptance.

Dover.—The surveyor to the Town Council last week brought up a bill for £141 for work done and wages paid for the electric light company, and it was ordered to be presented. The Town Clerk explained that they had a deposit of £200 in hand, but as there was other work to do this sum would not come out of that.

Battersea Polytechnic Institute.—The following appointments are open for session commencing September next: demonstrator in mechanical engineering, demonstrator in chemistry, pupil teacher (male) in training in art department, mechanic in engineering workshop. Particulars may be obtained of the secretary.

Llandudno Electric Supply Company.—The Llandudno Electric Supply Company, Limited, was registered on Tuesday. The first directors are Dr. James Nicol, J.P., Dr. William Nicol, Messrs. R. Conway, C.C., J. Bellis, J. Smith (Craigside), W. Arnold, and W. Ellis-Jones. Mr. R. Bellis is the solicitor, and Mr. W. Kingsland engineer to the Company.

Manchester District.—Messrs. Drake and Gorham have obtained the contract for the lighting of the Consolidated Bank at Manchester with about 80 lights of 16 c.p. The current will be taken from the outside supply. This firm appears to be very busy in the Manchester district, where, it will be remembered, they opened a permanent branch some time back.

Edinburgh.—Arrangements have been made for laying the foundation-stone of the electric light station on Monday, 25th inst., at 4 o'clock. The Lord Provost, Sir J. A. Russell, will perform the ceremony. There will be a dinner in the Council-chamber afterwards, and later a popular lecture in the Albert Hall, at 8 o'clock, by Prof. Kennedy.

Loanda Gas Company, Limited.—This Company has been registered with a capital of £50,000, divided into 4,000 preference and 1,000 ordinary shares of £10 each, to acquire a concession granted by the Municipal Board of the city of Loanda, in South-West Africa, for public and private lighting in the city of Loanda by means of gas, electricity, or any other system.

Clerk of Works Required.—The Electric Lighting Committee of the city of Coventry invite applications for the post of clerk of works for the erection of the buildings of their central generating station. The salary offered is £4. 4s. a week. Applications, with copies of testimonials, to be delivered at the office of the town clerk, 40, Bayley-lane, Coventry, by the 23rd inst.

English and Colonial Electric Light Company, Limited.—This Company has been registered with a capital of £50,000 in £1 shares. The object is to carry into effect an agreement between S. W. Maquay of the one part, and J. S. Forbes of the other part, for the acquisition of certain patents and inventions connected with electricity, and to carry on business as electrical engineers.

Bishopsgate Institute.—The Bishopsgate Institute, one of the foundations created out of various City funds under the auspices of the Charity Commissioners, is to be lighted by electricity, from the specification of Mr. W. H. Trentham, M.I.M.E., 39, Victoria-street, S.W., who is consulting engineer for the work. The current will be taken from the City of London Supply Company's mains.

Extra Pay.—The Finance Committee of the London County Council, in order to expedite the preparation of the plans, specification, and estimates for the generating station to be constructed in connection with the electric lighting of the Victoria-embankment and Waterloo and Westminster bridges, authorised the engineer to employ some of his assistants after the usual office hours. These officials are to be remunerated for their extra work.

Gravesend.—The Town Council have intimated to the National Telephone Company, Limited, that the Council are prepared to enter into one indivisible contract for three years for a wire from the chief constable's residence to the police station, and a wire from the latter to the local exchange for £16 per annum, the Council reserving the right of an additional wire from the office of the mayor, town clerk, or other Corporation official at £4 per annum.

Hotel-Lighting.—The electric light throughout the Royal Palace Hotel, Kensington, to which we referred in a previous issue, is in harmony with the furnishing and decorations, and is carried out with great taste. The reception-rooms contain fine examples of burnished pendants, brackets and rosettes. The contract was entrusted to the Walsall Electrical Company, Walsall, and credit is due to them for carrying out the work in the short space of time allotted.

Lancashire Boilers Required.—The London County Council invite tenders for two new Lancashire boilers and fittings at the Council's Central Works, Belvedere-road, Lambeth, S.E. Persons desiring to submit tenders may inspect the drawings and obtain the specification, bills of quantities, form of tender, and other particulars at the Engineer's Department, County Hall, Spring-gardens, S.W., upon payment of £1. No tender will be received after Monday, July 2.

Buxton.—For the protection of the Duke of Devonshire, Lord Playfair will move on the third reading of the Buxton electric lighting provisional order that unless his Grace's consent is given it shall not be lawful to break up or interfere with the Crescent, Buxton, or the streets lying between the Crescent and the eastern corner, and the Old Hall Hotel and the junction of Spring-gardens and Terrace-road. Other amendments strengthening this clause are also proposed to be inserted.

Wisbech.—After the usual tender from the Wisbech Lighting Company for lighting the public streets had been accepted by the Town Council last week, the Mayor said the above was the only tender that had been received, but he had a communication which had only come to hand on the previous day from an eminent firm of electricians with a view to lighting the town by electricity. No tender had been sent in. Mr. Whitehead said he did not think they ought to entertain the communication if there was no tender.

Engineer Required.—The Commissioners for Public Baths and Wash-houses for the Parish of St. Saviour, Southwark, invite, by July 3, applications for the post of engineer, to take charge of the whole of the baths and wash-houses machinery, including the electric lighting plant. The salary offered is £2 per week, apartments, lighting, and coal. Particulars of the duties can be inspected and forms of application obtained at the office of Mr. Henry Langston, clerk to the Commissioners, 32, Borough High-street, Southwark, S E.

Nottingham Central Station.—Operations in connection with the new electric light works, situate in Wollaton-street, have been marked by rapid progress. The various buildings are in a forward stage, while the brickwork of the chimney, rising to an altitude of some 160ft., being completed, the work of fixing a cast-iron cap, weighing close upon 9½ tons, is now being finished. The task of raising and placing the cap in position was entrusted to Mr. W. G. Furse, of 17, Burton-street, who had to design and construct special tackle for the purpose.

Shoreditch.—The Electric Lighting Committee of the Shoreditch Vestry reported, at a meeting of the latter last week, that they had considered the draft contract for the purchase of the Pitfield-street site for £33,500 for the erection of an electric lighting station, public baths, dust destructor, etc., and they recommended that the contract be approved, and that upon a formal contract from the Library Commissioners to take their agreed portion of the site being entered into, the seal of the Vestry be attached thereto. The Vestry ultimately decided to purchase the property.

Aberdeen.—At a meeting of the Watching and Lighting Committee of the Town Council it was agreed to light the new police buildings by electricity at a cost of £250. It was at first intended to light the building by gas, and piping for that purpose was laid down. In consequence, however, of the decision to use electricity, gas fittings will be unnecessary, and on these a saving on the original contract of £100 will be made, so that the net extra cost of introducing the electric light will be £150. Trinity Hall, which belongs to the seven incorporated trades of the city, is being extended at a cost of about £8,000, and will be lighted throughout by electricity. The architects are Messrs. Brown and Watts.

Digitized by Google

Edison and Swan Company.—Notice is given that an extraordinary general meeting of the Edison and Swan United Electric Light Company, Limited, will be held at the Cannon-street Hotel on Tuesday, July 3, at a quarter past 12 o'clock in the afternoon, to consider and, if approved, to pass the following resolution—viz., "That the provisional agreement dated June 5, 1894, submitted to this meeting and expressed to be made between the Swan United Electric Light Company, Limited, and this Company for a sale of the Swan Company's undertaking to this Company for debenture stock of this Company be, and the same is hereby, approved."

New Installations in Liverpool.—The Northern Electrical and Ventilating Company, of 3, Smithfield-street, Tithebarn-street, Liverpool, are making great strides in Liverpool and surrounding districts. They have just completed the lighting of the elaborate new offices and warehouse of Messrs. Boyd and Grant, the well-known provision merchants, of Liverpool and America, and have also taken the contract for lighting the adjoining building. In addition to these, the company are ventilating the new Cunard works and Messrs. Clarke and Son's tobacco factory, to say nothing of the other important contracts they now have in hand. The company are to be congratulated on such a record at the close of the first year of their establishment.

Moss Side.—At the last meeting of the Local Board, Mr. Marr, of the Collier-Marr Electric Lighting Company, submitted a proposal for the electric lighting of some of the leading thoroughfares of the district. He said that in place of 156 of the gas lamps now in use the company proposed to fix electric lights of 36 c.p. in 49 of them, and lights of 16 c.p. in 56 others. In addition, it was suggested there should be four arc lights at four points of the district. This would give a total illuminating power of 10,626 candles, against the present illuminating power of 2,026 candles, and the company would undertake to provide this at a cost of £533 per annum. Mr. Marr was requested to submit his proposal in writing, and this he promised to do.

Electric Lighting of Glasgow.—At a meeting of the Watching and Lighting Committee, Bailie Primrose, the convener, on behalf of the sub-committee in connection with the proposed lighting by electricity of certain additional streets of the city, reported that they would not feel warranted in recommending that the scheme be gone into, the cost showing such an increase on the present system of lighting. They recommended, however, by way of experiment, that 12 incandescent gas lamps should be erected in St. Vincent-street, between Buchanan-street and Renfield-street. From experiments made by Mr. Hamilton, the superintendent of lighting, within the last month, it was believed that the present lighting would be vastly improved by these lamps without extra cost. It is proposed to reduce the price of current to private consumers from 7d. to 6d. per unit.

The Derby Exhibition.—The exhibitors at this exhibition, with a number of friends, dined together recently at the County Hotel. Amongst those present were Messrs. Crowther, J. E. Stewart (engineer of the electric light station), H. Baker, Lineham, Fellows, Maxwell, Covington, Myers, Windham, Seward, Fryer, Roberts, and Rull. Mr. J. E. Stewart occupied the chair. After full justice had been done to an excellent repast, an enjoyable evening was spent. In replying to the toast of the evening—"The Mayor, Corporation, and Electric Lighting Committee"—Mr. Stewart said that he was pleased to have heard that many of the exhibitors had booked some very good orders. Considering that the whole of the firms exhibiting might be considered rivals in trade, a spirit of good feeling and friendliness had existed during the whole of the time that the exhibition had been open.

New Electric Vehicle.—Messrs. Taylor, Cooper, and Bednell, of Coventry, have just completed the construction of a vehicle propelled by electricity, the invention of Messrs. Blumfield and Garrad. The car has the appearance of a small wagonette with seats for four. It runs on four pneumatic-tyred wheels, with bearings. The frame, which is carried on springs, is constructed of weldless steel tubing similar to that used in the manufacture of cycles. The current is stored in 24 cells, 12 beneath each of the two seats, and is conducted to a motor underneath the vehicle. The motor is nominally of 1 h.p., capable of rising to 2 h.p. for a short time in case of necessity, and communicates its power to the rear axle by means of differential speed gear and chain. A speed of from 3½ to 13 miles an hour is said to be attainable. A trial has been made, the car being taken to Birmingham, a distance of 18 miles, and an average of eight miles an hour is stated to have been attained.

Plymouth.—At a meeting of the Borough Council on Monday the Special Purposes Committee reported the receipt of a report from the town clerk with regard to the Plymouth, etc., Gas Bill He stated that in accordance with the resolution of the committee of March 21 last a petition was lodged against the Bill. One of the points of the petition was that the company should not be at liberty to apply for powers to supply electricity. The company's counsel abandoned the provisions of the Bill relating to electricity so far as the borough of Plymouth or the outside area, the subject of the borough extension proceedings, is concerned. In the discussion which took place on the subject of the Bill, Mr. J T. Bond pointed out that the Corporation was now alone endowed with the power to proceed with the electric lighting of Plymouth. Mr. Bellamy said that gas was probably about to be superseded by electricity, which was coming to the front by leaps and bounds. It was ultimately decided not to take action for the acquisition of the gasworks by the Corporation.

Weston-super-Mare.—The Electric Lighting Committee of the Town Commissioners considered on the 2nd inst. letters from Messrs. E. C. De Segundo, Mr. Douglas C. Bate, Mr. F. W. Ball, and Mr. G. F. Metzger, offering their services to the Board. Mr. Harvey proposed that the committee should not select an electrical engineer that day, but that they advertise and offer a premium of 50 guineas for the best plans, specifications, and report, and that the same be sent under a motto. No one seconded the proposition, and Mr. Deverell thereupon moved, and Mr. Boyden seconded, "That Mr. Medhurst's offer to report fully and to advise the committee on the questions of electric lighting, and tramways, and on the utilisation of dust destructors for the production of electric power, at a fee of 50 guineas and personal out-of-pocket expenses connected with visits to Weston, be accepted, it being distinctly understood that the Board does not commit itself to Mr. Medhurst for anything further than this first stage, and shall be at liberty to appoint any other engineer afterwards, if so disposed. If employed to carry out any or either of the works, the 50 guineas before mentioned to be merged in Mr. Medhurst's commission." The proposition was carried, Mr. Harvey alone dissenting. The clerk was instructed to prepare and forward Mr. Medhurst the necessary contract. When these minutes were brought up last week for confirmation, Mr. Masters said that the engineer selected should have been Mr. Hammond. The Clerk pointed out that the committee had been given the power of selection. After further discussion, the minutes were confirmed.

Coventry.—The Electric Light Committee of the City Council have received tenders for the erection of the buildings of the electric light station in Sandy-lane, as follows: Messrs. Foster and Dickson, Rugby, £9,090; Mr. Charles Garlick, Coventry, £7,860; Mr. John Bowen, Birmingham, £7,742; Messrs. Liggins and Strong, Coventry, £7,534. 12s.; Messrs. T. and H. Herbert, Leicester, £7,382; Messrs. G. F. Smith and Sons, Leamington, £7,138; and Mr. C. G. Hill, Coventry, £6,829. The Council have accepted the tender of Mr. C. G. Hill. A clerk of the works is advertised for at a salary of four guineas per week. The site of the works adjoins the premises of the cotton company, and is bounded by the Coventry Canal, and there is also a siding from the L. and N. W. Railway. The buildings to be erected will cover only a portion of the ground, ample room being left for any extensions and additions that may be required in the future. Messrs. G. and I. Steane are the architects, and Mr. Robert Hammond is the consulting engineer. Included in the buildings to be erected will be an engine-house, boiler-house, coal-stores, and pump-room, together with the usual offices. The system which has been adopted for the incandescent lighting is the alternating-current high-tension converter system. There will be 2,176 yards of cables, run, on one side only, through the following streets in the proportions named: Broadgate 80 yards, Smithford-street 317, Fleet-street 125, High-street 117, Earl-street 173, Jordan-well 153, Hertford-street 276, Cross-cheaping 187, Burges 183, Hay-lane 167, Priory-row 228, and Bayley-lane 270. A letter has been received from the Local Government Board sanctioning the raising of a loan of £20,000 for the purposes of electric lighting.

Lighting of Bedford.—The Electric Light Committee of the Town Council recommended last week that application should be made to the Local Government Board for sanction to the borrowing of £12,000 for the purpose of providing the necessary buildings, machinery, and plant for supplying electrical energy within the borough, in accordance with the plans and estimates prepared by Mr. F. H. Medhurst, M.I.E.E. Mr. Richards, in proposing the adoption of the report, said that the committee had obtained an interview with Sir Hugh Owen, of the Local Government Board, and they received the advice to apply for a loan of £12,000, instead of £10,200, in order to meet emergencies that might arise, and if found necessary to increase the area. It was thought desirable that the authority should know their present position financially, and he might say that the balance of their outstanding loans was £25,000. This would require a rate for the next two half years of 6½d. in the £. At the end of that time their rate would be reduced, with regard to the outstanding loans, to 3½d. A £12,000 loan for 30 years would be met by a rate of 1d. in the £ each half-year, so that they would have reduced their liability by a 3½d. rate, and increased it by a 1d. rate. But they must remember also that they hoped to get a return of this money from the use of the light in the town, and the committee on that ground had felt that there was no responsibility in the matter. Besides, it was almost impossible for them to go wrong, for their plans were first overhauled by the engineers, and afterwards by the Local Government Board. It was certain that they could obtain the £12,000 loan at 3½ per cent., and they hoped to get it at 3 per cent. Mr. Geoffrey Howard seconded, and the report was adopted.

Beverley.—A motion was submitted by Mr. Whiteing to the Town Council last week that a committee should be appointed for the purpose of investigating the process now adopted in other towns for the production of steam power from town refuse, and that such committee should report the result of their investigations. The Livet system, which was in operation in Halifax, appeared to be most satisfactory. He was informed that every description of refuse could be consumed, and estimating the amount which would be available in the borough, he believed they could produce by this system as much steam as would be raised by 1,500 tons of steam coal; but for the purpose of his argument he would put it at 1,200 or 1,300 tons. The question then arose, what could they do with this power? They used power at the outfall works which cost them £40 a year in gas, while they paid Mr. Palmer between £80 and £90 a year to remove the refuse. The whole of this, he held, might be saved. For a town the size of Beverley the plant for utilising this refuse would be about £1,000 or £1,100, which, if borrowed for 50 years, would cost

Digitized by Google

about £46 per annum, or if for 30 years a little over £65. He had shown how £120 at least could be saved, while if they procured a stone-breaking machine the reduction of expenditure would approach £250. They could use this fuel at the baths, and, if deemed necessary, they could, by getting a dynamo, introduce electric lighting. He had no particular scheme to advocate; all he asked at present was for the appointment of a committee who would investigate and report upon the adaptability of the system to Beverley. Mr. Norton seconded the motion. Mr. Chilman said it would be a waste of time to enquire into the scheme when it was in such a stage that no place could pronounce it satisfactory. The Mayor said that two years ago a gentleman sent him a lot of papers on this subject, but he (the mayor) could see no advantage to Beverley by adopting such a system. Mr. Whiteing, in reply, said he was advocating no scheme, and the committee could incur no expense; all he asked for was a committee to enquire into the subject. The motion was lost by one vote.

Results of Tenders.—The following tenders were received by the Paddington Board of Guardians for the electric lighting of the female wards of Paddington Infirmary, according to the specification of Mr. A. W. Sclater, A.M.I.C.E.:

H. Thorpe	£284	15	0
Benham and Sons, Limited	235	0	0

Yarmouth.—At a meeting of the Town Council, the Electric Lighting Committee presented the following report: "The borough surveyor stated it would now be necessary to provide an overhead travelling crane for the engine, the cost of which had been provided in the estimates. He had ascertained that the cost of a new crane with rails and fixing would be £163, and he had been offered a second-hand crane at Birkenhead for £38, and two others at Gloucester for £35 and £50 each, which with fixing and new girders would cost £92 against £163 for a new crane. The committee instructed him to inspect the cranes, and, if suitable, purchase the best of the second-hand cranes, and to take the necessary steps to fix it, so that it should be in place for Messrs. Crompton to fix their machinery with. The surveyor was further instructed to interview Mr. Preece to ascertain whether it would not be possible to obtain the water for condensing purposes from a well or wells on the Denes instead of from the river. He was directed to obtain tenders for any necessary pipes, and to carry out such other works as might be necessary to obtain a supply of water for the condensing plant, provided that such works did not exceed the amount of the estimates. The surveyor stated that it was now necessary the Council should fix the rate of charge for a supply of electricity to private consumers, and also the rules upon which such supply could be obtained, and he submitted the rules adopted in Bradford, Hull, St. Pancras, and Dublin. The committee instructed the surveyor to confer with Mr. Preece, and submit a set of rules with Mr. Preece's recommendation as to what the charge should be. The town clerk stated that the question of improving the lighting of Gorleston had been referred by the Council to the Electric lighting Committee. The surveyor stated that he had no doubt but that Gorleston could be as well lighted by electricity as by gas for the same amount now paid for gas lighting, and he recommended that the matter should stand over for the present until the electric lighting works had been at work some time, to see if the whole of their plant was not in use for Yarmouth. If it were not, the lighting of Gorleston might be proceeded with. The committee resolved to recommend the Council to allow the matter to stand over for the present." Mr. Ruddock moved, "That immediately after the electric lighting works are started in Yarmouth, the surveyor report on the lighting of Gorleston and Southtown by electricity." Mr. Press, who seconded this, said if Gorleston and Southtown had to wait until it was ascertained whether the whole power of the plant would be absorbed by Yarmouth, there would be an indefinite delay. When the gas bills came in they took one's appetite away altogether. Mr. Ruddock's proposition was agreed to. The several other recommendations made by the committee were adopted. The surveyor presented a lengthy report on the question of the Livet system of generating steam through the destruction by combustion of town refuse. He had visited several towns to see the system in operation, and his conclusions were—"The system has, in my opinion, not yet had sufficient trial to warrant me advising you to adopt it in any way at present. I recommend that you adopt a policy of watching other people's experiments, which will cost you nothing."

Larne.—At a meeting of the Town Commissioners held on Tuesday, the Chairman stated that in accordance with the instructions of the Board he, with their clerk, waited upon Mr. J. W. M'Ninch, solicitor, who had written to Messrs. J. E. H. Gordon and Co., Limited, the electrical contractors, on the subjects raised at their last meeting, and the clerk had since received a reply from Mr. Norris, receiver and manager. The clerk then read two letters from Mr. Norris, in which he stated he would agree to the insertion of Clause 3 in the agreement, which is with reference to the erection of new lamps at the company's expense. The Board then proceeded to discuss a motion by Mr. Fullerton, which proposed that they should light at dusk instead of at sunset. A number of members expressed the opinion that the company should exercise some discretion, and that on a dark, foggy evening in winter they should light rather earlier than usual, while on a clear evening the lighting might be delayed for some time. The clerk read a letter on this subject from Mr. Turner, resident engineer to the company, who appended a time-table of the hours at which he proposed they should light. Mr. Turner afterwards appeared before the Board, and said that his reason for proposing that they should adopt this table was to avoid complaints. With reference to the proposal by some of the Commissioners that they should light earlier on dark evenings and later on clear evenings, the difficulty was that the advantage would be all the one way; if they lighted at a later hour than that laid down in the table there were certain to be complaints, and the Commissioners also had the advantage if the hours of lighting were earlier on dark evenings. Mr. Turner having left the Board-room, Mr. Fullerton altered his motion to read: "That former resolutions and decisions of the Board fixing the time of lighting public lamps as from sunset be rescinded, and that 'dusk' be the time for lighting in future, and that dusk be understood and explained as by table submitted per Mr. Turner." This motion was passed unanimously. It was then agreed that the agreement between the Larne Town Commissioners and Messrs. J. E. H. Gordon and Co., Limited, electrical engineers, with reference to the contract for public lighting of the town of Larne for the next three years be completed, seeing that Mr. Norris, receiver and manager, has agreed to the insertion of Clause 3 therein.

Electric Lighting of Cardiff.—In the course of a communication to a Cardiff paper Mr. Sydney F. Walker says: "About a week ago appeared a letter from Mr. Coles, an electrical engineer, of Swansea, pointing out that lamps were now obtainable taking a smaller current than those commonly in use, and, therefore, costing less to run, and Mr. Coles went on to draw the inference that the cost of the electric light in Cardiff, when using these lamps, at the price of 6d. per unit, would be only slightly in excess of the cost of gas. Mr. Coles forgot to mention that if lamps are used which, being worked at a higher state of incandescence, do not require as much current to furnish their normal 16 c.p. on any given supply service, the life of the lamps themselves is very considerably reduced; so that the actual cost of the light is very slightly reduced, if at all. As the manufacture of these higher incandescent lamps improves, the cost of lighting will steadily decrease. In fact, the improvement in the manufacture of the lamps is one of the sources from which decreased cost in the future will be obtained. At the present time, however, the facts are exactly as stated in your leader which preceded Mr. Coles's letter—for the same candle-power and the same time, the electric light will cost approximately double that of gas; but considerable economy may be effected in the lamps burnt in rooms not constantly in use, by turning them on when entering the room and turning them off on leaving it. There will also be considerable economy in the cost of interior decorations, and in particular of curtains and similar fabrics. While I am on the subject may I once more urge upon the Corporation the advisability of adopting the large incandescent lamp, in place of the arc, for street-lighting? It is not yet too late. The lamp-posts will answer quite as well, if clear glass be substituted for the obscured glass now fixed in them, for the large incandescent lamps as for the arcs, while the adoption of the large incandescent lamp will save money and will save the Council many a bad quarter of an hour. The reasons which induced many engineers to so strongly favour the arc lamp are fast disappearing. It appears to be more than doubtful if the much-vaunted "rectifier" will even produce a current that will work an arc lamp properly, and this 18 months after it was supposed to be so perfect and so well known that only an ignoramus would have questioned the advisability of its adoption. And if the rectifier is abandoned, as it undoubtedly will be, half the reasons for the use of the arc are gone, since the light given by the arc furnished by an alternating current is only half as powerful as that given by an arc furnished by a continuous current in the direction in which it is required. And if we take from the remaining half the percentage of the light rays absorbed by the obscured glass, the difference between what is left and the light given by the large incandescent lamp absorbing the same energy will be, if anything, in favour of the large incandescent lamp. In London, and everywhere else, too, the large incandescent lamp is steadily supplanting the arc. Where, two years ago, the former was not to be seen anywhere, now it is seen side by side with its rival, and steadily gaining ground. The "rectifier" is the last fence. Let Cardiff county councillors go for it boldly, and they will find safe and

Digitized by Google

easy riding on the other side." A meeting of the Lighting and Electrical Committee of the Cardiff Corporation was held at the Town Hall on Monday under the presidency of Alderman Carey. The meeting was called for the purpose of making a preliminary selection of candidates for the positions of engine fitters at the new electric lighting station. There were 136 applications for the four appointments, the salary offered being £2. 2s. a week Mr. Riches asked whether it was intended that any of these fitters should do repairs to the electrical plant. The Chairman replied in the negative, and explained that they would simply look after the driving engines and effect any repairs that were necessary from time to time. They would work a system of eight hours' shifts, with a spare hand in case of emergency. Ten candidates were selected for submission to a future meeting of the committee, when the appointments will be made. A meeting of the Lighting and Electrical Committee of the Cardiff County Council was held at the Town Hall on Tuesday, under the presidency of Alderman Carey. Mr. Massey reported that with the exception of a few yards of piping in Working-street the whole of the mains were laid for the electric lighting cables. One large engine had been delivered, and one large and two small dynamos had been erected. All the dynamos had arrived, and the second large engine was on the way. The erection of the engine had been stopped pending the appointment of the four engine fitters. When they had been appointed there would be at least a month's work for them in the engine-house.

PROVISIONAL PATENTS, 1894.

JUNE 11.

11276. **Improvements in and relating to electric incandescent lamps.** Rudolf Langhans, 61, Fore-street, London.

11280. **Improvements in jointing electric conductors.** William Geipel, 49, Kidbrook Park-road, Blackheath, London.

11286 **Improvements in electric arc lamps.** Henry Capel Lofft Holden, Royal Arsenal, Woolwich.

11312. **Improvements in electric accumulators or secondary batteries.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (La Société Electro-génique, France.)

11320. **Improvements relating to telegraphic and telephonic transmission.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Michael I. Pupin, United States.) (Complete specification.)

11323. **Improvements in apparatus for the automatic transmission of signals through telegraph lines and cables.** Alexander Muirhead and Angus Fraser, 124, Chancery-lane, London.

11338. **System of electric signalling.** Charles Molyneux Houghton, Gayton, Cheltenham. (Louis F. C. Rich, United States.)

JUNE 12.

11364. **Improvements in dynamo-electric machines.** William Lowrie, 152, Stroud Green-road, Finsbury Park, London.

11418. **Improvements in telephone transmitters.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States.) (Complete specification.)

JUNE 13.

11439. **Improved electric indicator.** Henry John Wagg, 40, Bryanston-square, London.

11452. **Improvements in connectors for conductors used with electrical apparatus.** Rookes Evelyn Bell Crompton and Herbert John Dowsing, 55, Chancery-lane, London.

11483. **Improvements relating to the generation of electricity.** John Evelyn Liardet, 9, Warwick-court, Gray's-inn, London.

JUNE 14.

11559. **Improvements in magneto-electric motors.** Henry Lüdeke, Ernst Louis August Lüdeke, Arthur James Thorman, Ernest de Bunsen, and Edward Madge Hore, 4, St. Benet-place, Gracechurch-street, London.

11587. **Improvements in the process of and apparatus for the electrolytic decomposition of solutions and for the immediate separation therefrom of the liquid or dissolved electrolytic products.** Léon Paul Hulin, 53, Chancery-lane, London. (Date applied for under Patents, etc , Act, 1883, sec. 103, November 25, 1893, being date of application in France.)

11601. **Improvements in printing telegraph instruments.** Oscar Lillian Kleber, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JUNE 15.

11606. **Improvements in separators for electric storage cells.** F. R. Davenport, 1, Granville-road, Eastbourne.

11613. **An electrical minnow for fishing purposes.** Henry Wren Rowland, 3, Regent-road, Crosby, Liverpool.

11628. **Improvements in the mode of and means for suspending electric lamps, lanterns, shades, and other such articles.** Frank Hewitt, 77, Colmore-row, Birmingham.

JUNE 16.

11684. **Improvements in and connected with electrical safety fuses.** Alexander Marr, 70, Market-street, Manchester,

11701. **Improvements in electric fire-alarms.** George Richard Neilson and Alfred Charles Brown, 50, Old Broad-street, London.

11713. **Improvements in or connected with telephones.** John Goulding, 12, Basinghall-street, London.

SPECIFICATIONS PUBLISHED.

1891.

18597. **Electrolysis.** Andreoli. (Second edition.)

1892.

11624. **Coin-operated telephone apparatus.** Lake. (Noriega.) (Second edition.)

14056. **Electric motors.** Lake. (Stanley and another). (Second edition.)

23805. **Arc lamps.** Bombe. (Second edition.)

1893.

1229. **Secondary batteries.** Lloyd. (Second edition.)

4106. **Secondary battery plates.** Epstein.

10398. **Electrical communication with vessels or buoys.** Lenox.

10441. **Conduit electric railway.** Hughes. (De Voe.)

10569. **Regulating the temperature of electrical heating, etc., apparatus.** Crompton and Dowsing.

10584. **Electrolytic apparatus.** Castner. (Second edition.)

11426. **Electric motor.** Todd and Lewis.

12153. **Measuring, etc., electric currents.** Waterhouse.

12362. **Marking meat by electricity.** Armstrong and others.

12523. **Electric brushes, etc.** Wollaston.

13336. **Electrolytic production of nickel, etc.** Hoepfner.

13412. **Electric generators.** Conrady.

14091. **Electric fuses.** Brain.

14202. **Dynamo-electric generators and motors.** Pyke and Harris.

1894.

139. **Telephone exchange systems.** Callender.

5663. **Cut-offs for gas, electric, etc., conduits.** Kleine and Lindner.

6742. **Electric switch.** Siemens Bros. and Co., Limited, and Grimston.

8149. **Electrical measuring instruments.** Lake. (Van Vleck and another.)

NOTES.

Telephony in Germany.—Greifswald and Stralsund are to be telephonically connected.

Exhibition at Kiel.—A German national exhibition is to be held at Kiel from August 4 to 19.

Central Station at Donaueschingen. — Messrs. Schuckert and Co., of Nuremberg, will carry out this installation.

Electric Lighting at Munich.—An electric installation is being put up for the lighting of the Central and Rangir railway stations.

Telephony at Gera.—A movement is on foot for the establishment of telephonic communication between Gera, Zeitz, Weissenfels, Halle, and Berlin.

Electric Lighting at Combourg.—M. Corvaiser is projecting an electric light installation for this town in Ille-et-Vilaine. It has 6,000 inhabitants.

Internationale Elektricitats-Gesellschaft.—This Viennese Company has declared a dividend of 6 per cent., after allowing for depreciation, reserve, etc.

Kashmir Telegraphs.—Arrangements are in progress to incorporate the Kashmir State Post and Telegraph Office with the Imperial Posts and Telegraphs.

Alarming Intelligence.—Extract from an electrical contemporary, June 21, 1894: "This is the last number of —— which will be published . . . . ."

Konigsberg Tramways.—The Union Electricity Works will take over the systems of the Königsberg Horse Tramway Company not later than May 1, 1895.

Electric Lighting at Madras.—A proposal is now before the Government of India for lighting with electricity the Presidency post and telegraph offices in Madras.

Lundy Cable.—The cable was tested on Friday, and found perfectly sound at the island end. It was reported some time ago that the cable was wearing at that point.

Mining Institute of Scotland.—At the last meeting of this society a further discussion took place on Mr. J. T. Forgie's paper on "Electric Haulage Plant at Dumbreck Colliery."

Electric Lighting at Ancenis.—The Municipality are in course of making arrangements with a company for the establishment of a central electric lighting station in the town.

Mr. Edison.—It is announced, according to one news agency, that Mr. T. A. Edison is ill owing to overwork. According to another, however, he has hurt himself by falling down some steps.

The Pneuelectric Carriage.—This is the name which has been given to the electric vehicle devised by Messrs. C. R. Garrard and T. W. Blumfield, which we described in our "Business Notes" last week.

Price Down at Altona.—Messrs. Schuckert and Co. announce that the price of current will be reduced at Altona by about 6 per cent. owing to the fact that there are now nearly 10,000 lamps connected.

Electric Traction in Hamburg.—All the formalities have now been gone through in connection with the projected high-level electric railway between Hamburg and Altona, to which we have previously referred.

Berlin-Vienna Telephone. — Work in connection with the telephone line between Berlin and Vienna, which is to be ready by November, is being pushed forward. The charge to be made is 4s. for three minutes' conversation.

Messrs. Schuckert and Co.—The net profit made for the year 1893-94 by the Elektricitäts-Aktiengesellschaft vorm. Schuckert and Co., of Nuremberg, is £105,196. The directors recommend the payment of a dividend of 9 per cent.

Lighting at Budapest.—The National Theatre has hitherto been lighted by an electric plant of its own, but the Minister of the Interior has given instructions for it to be connected with the mains of the Hungarian Electricity Company.

An Advantage.—Among the advantages set forward on behalf of the Olympic Music Hall, which is to be put up to auction to-day, is the fact that the buildings are fitted throughout with a duplicate system both of electric and gas lighting.

A Funny Electrician.—The hero of Mr. J. M. Barrie's play, "The Professor's Love Story," which has been produced this week by Mr. E. S. Willard at the Comedy Theatre, is a gentleman who studies electricity, and when he falls in love does not know it, but takes medical advice to obtain a cure.

Brunswick.—The Brunswick Street Tramway Company are negotiating for the substitution of electric for horse traction on their lines. The firms who have the matter in hand are the Allgemeine Elektricitäts Gesellschaft of Berlin, Messrs. Siemens and Halske, and Messrs. Schuckert and Co.

Tramway Traction.—The Tramways Committee of the Leeds Corporation are somewhat perplexed in regard to the future working of the Leeds tramways, and they have this week visited Newcastle and Edinburgh with a view to obtain definite information. In Edinburgh the cable line will be inspected. What about electric traction?

Chambery.—Messrs. Thivel and Bravais are pushing forward the works in connection with the utilisation of the power of the Granier Falls. The quantity of water is not great, but a head of 2,000ft. is available which will yield 13,000 h.p. to 14,000 h.p. After providing for current for the electric lighting of Chambéry and intermediate localities, there will be power remaining for other purposes.

The Dodge Repeated.—Evidently the *Financial Times* has not read the note in our last issue entitled "An Advertising Dodge," as it continues to publish news from the *Cable Gazette* about the plague in Hong-Kong. Is it possible that the Broad-street cable clique has found other means futile, and has acquired an interest in "absolutely trustworthy" so as to advertise the *Cable Gazette*?

Electric Underground Railway for Vienna.—The Anglo Bank, in conjunction with Messrs. Siemens and Halske, are applying for a concession for an electric railway between the Ferdinand Bridge and Penzing. The line would be about 3½ miles long. It would be carried underground for a certain distance *viâ* Stefansplatz, Graben, and Opernring, but at the Penzing end would be a street tramway.

Glasgow Tramways.—Next week the Corporation will assume the responsibility of working the city tramways. They do not at the moment seem inclined to go in for electric traction, but they appear to be open to progress in a small way, for although to begin with oil will be used for illuminating purposes, the lamps have been constructed in such a way that they will be suitable for electric light should it be adopted.

Telegraphs in Kashmir.—The telegraphic party in Kashmir under Mr. Olphert's superintendence have crossed the passes and recommenced work, says an Indian contem-

Digitized by Google

porary, but the whole party suffered severely from snow blindness as fresh snows have fallen. They are now recovering, however. Telegraphic communication has been reopened with Gilgit *vid* Kashmir. The unfinished line of last year was but little damaged.

The Transvaal.—According to a German contemporary, Messrs. Siemens and Halske propose to erect at Witwatersrand, in the Transvaal, a central electricity station in order to supply the mines with electrically-transmitted power for small machinery, such as pumps and drills. Both water and steam power will be employed. A local agent of the firm has distributed circulars with respect to the project among mining concerns, and it is said that the scheme is likely to receive general support.

Lighting Refrigerating Premises.—In a paper read at the recent meeting of the Incorporated Association of Municipal and County Engineers, on "The Refrigerating Lifting, and Haulage Machinery, Electric Light Installation, and Cold Stores of Messrs. Nelson Bros., Commercial-road, Lambeth," it was mentioned that the electric current is generated by two low-speed Paterson and Cooper dynamos, coupled direct to two of Gwynne's high-speed double-acting engines. There are 1,600 incandescent lamps in different parts of the stores.

Telegraphy in Asia.—M. Venukoff has been giving the Société de Géographie some particulars respecting the establishment of the telegraph in Asia. The Chinese have opened telegraphic communication between Pekin and Kashgar. One of the first telegrams sent from the latter place to the Chinese capital was one from the Russian consul-general. It consisted of 18 English words, and the cost was about 3s. 9d. The distance is about 2,400 miles. It is proposed to establish a telegraph line, 200 miles in length, between Kashgar and Och in Russian Turkestan, so as to have a new line of telegraphic communication across Asia.

Society of Arts Conversazione.—At the invitation of the council of the Society of Arts, about 3,000 ladies and gentlemen were present at a conversazione at the Imperial Institute on Friday evening last. Sir Richard Webster, Q.C., M.P. (chairman), Sir Frederick Bramwell, F.R.S. (deputy-chairman), and the other members of the council received the company in the vestibule. The principal galleries of the institute were thrown open to the guests, including those containing the collections illustrating the natural resources of the colonies and India, and the exhibition of British artistic and decorative pottery, china, and glass.

Lighthouse Communication.—Materials have been dispatched from Kirkwall by the steamer "Fawn" to the Fair Isle, which lies midway between Orkney and Shetland, to be used in connection with the scheme for instituting telegraphic communication between lighthouses and the coasts. A telephone line is to be constructed from the lighthouse to the south of the island, so that in the event of shipwreck, the news may be promptly forwarded from the one place to the other. At present there is a lifeboat at the south end of Fair Isle, and it is hoped that by means of the telephone the rescue service in case of shipwreck will be made much more efficient than at present.

Northern Society of Electrical Engineers.—On Saturday last a party, consisting of about 40 members, paid a visit to Liverpool. They were received at the Oldham-place station of the Liverpool Electric Supply Company by Mr. A. Bromley Holmes, C.E., who explained all the points of interest. The members subsequently visited the overhead electric railway and inspected the generating station, permission having been given by Mr. S. B. Cottrell, the engineer for the company. The party then proceeded to the National Telephone Company's new switch-room, where the system was explained. This is the first of a series of excursions to be made during the summer, the next one being to Antwerp on July 20.

Personal.—Mr. B. J. Diplock has been appointed secretary of the Fowler-Waring Cables Company, Limited, *vice* Mr. D. Stephen, who resumes his duties as accountant of the company. Mr. James Tiddy, late manager of the Central and South American Telegraph Company, has been appointed electrician-in-charge of the testing-rooms of the Fowler-Waring Cables Company, Limited, at North Woolwich. It is sometimes said that the services of electricians are ignored by the lay Press, but at last electrical merit has been recognised, for *Ally Sloper* has not only published a portrait of Captain Ronald Scott, but also conferred upon him the diploma of F.O.S., while he is referred to as the English Edison. Mr. Edison has now cause to hold his head up.

The Underground.—We referred to this railway last week, and made certain suggestions. Mr. Weir, M.P., is apparently much troubled about this matter, but he will be Weiry—we mean weary—before he finds it comfortable to travel by this line. On Friday last, in the House of Commons, he asked the President of the Board of Trade whether his attention had been drawn to certain articles and correspondence as to the state of the atmosphere in the underground railway, and the means of purifying it; and whether he would take steps to deal with the matter effectually. Mr. Bryce said he had himself experienced the state of the atmosphere in the underground railway, but Parliament had not entrusted the Board of Trade with any powers to enable the Department to deal effectively with the mischief.

Electrical Exhibition at Budapest.—On the 10th inst. there was opened at Budapest by the Hungarian Minister of Commerce an exhibition of electrically-driven machines, to which we have referred on previous occasions. This exhibition has been carried through by the Ministry of Commerce on the initiative of the Commercial Museum, the object being to demonstrate to the public the importance of electricity for power purposes. There are 22 Hungarian and 23 foreign exhibitors, who are represented by over 200 machines of various kinds. Current is obtained from the street mains of the Hungarian Electricity Company, who furnish it free. Messrs. Ganz and Co. have also furnished the electric motors gratuitously, as have Messrs. Siemens and Halske part of the fittings. Exhibitors have obtained their space without any charge whatever.

Electric Launches.—A representative of an evening paper has held an interview with Earl Russell on the subject of launches on the Thames. When asked whether he preferred an electric launch, his lordship is reported to have replied: "Not at all. Mine is a steam launch. Electric launches are all very well for those who like to potter about up and down two or three reaches. You can do more with steam, and are independent of charging stations, and can go where there are none—up canals, for instance. Wherever you are you can get coal of some sort. You have the bother of keeping an engineer, but in the case of electric launches the accumulators run up the weight and the expense, involving, I should think, an annual outlay of 20 per cent. of their first cost. If you have an engineer who can do odd jobs, £5 will cover the cost of ordinary repairs on a steam launch. However, in either case the expense is laying up the boat in the winter, and getting her into commission again. Unfortunately, a number of steam launch owners know nothing

Digitized by Google

about their working, nor do their so-called engineers." Asked as to whether he had tried oil launches, Earl Russell replied in the negative, adding that he had smelt them.

National Boiler Insurance Company.—We have received the report for 1893 of the chief engineer of the National Boiler and General Insurance Company, of Manchester, which contains much information of value to steam users. There were 20 formal investigations under the Boiler Explosions Act last year, and general particulars are given of the finding of the Court in each case. Altogether 27 actual explosions were reported, the vertical boiler, as usual, heading the list. The inspectors met with a very large number of defects arising from external corrosion. Wasting of this nature has been one of the principal causes of explosions, and during the last 10 years 63 explosions of steam-boilers have occurred which are directly attributable to weakening caused by external wasting. Details, with illustrations, are given of the explosion of a vertical boiler owing to over-pressure; of a water-tube boiler owing to accumulation of deposit; of a vertical multitubular boiler owing to external corrosion; and of a vertical boiler owing to restricted head room, which prevented the safety-valve operating.

Electrolytic Decompesition of Water.—M. Le Blanc, in a paper published in a German periodical, upholds the view of the primary decomposition of water, and replies to the objections brought forward by Arrhenius. The increase in the electrolytic decomposition of water by the addition of an electrolyte is explained, not by an increase in the degree of dissociation of the water, but in the capability of ion formation. He also explains the fact that hydrogen is not immediately liberated during the electrolysis of an alkali salt with a mercury cathode, by stating that the potassium ions give up their electricity to the mercury more readily than the hydrogen ions. That hydrogen ions are present in water is shown also by the fact that potassium reacts readily with water and not with paraffin. In the case of solution of various metallic cyanides in potassium cyanides, he points out that cadmium is easily separable, but platinum scarcely so, which is hard to explain on a secondary decomposition hypothesis, unless the electro-deposited platinum were soluble in potassium cyanide; this, however, he proves experimentally is not the case. He finally points out that the primary decomposition theory has the advantage of simplicity.

Observations on the Nature of Phosphorescence. Mr. Herbert Jackson, in a paper read before the Chemical Society, dealt first with the readiness with which the phenomena of phosphorescence may be studied by using a mechanical pump capable of very rapidly giving high vacua (Fleuss's pump). The author considers that in many cases the phosphorescence cannot be ascribed to impurities, but that a presumably pure substance yields in several instances phosphorescence of different colours. The main portion of the paper is occupied with an attempt to show that the phenomena of fluorescence, phosphorescence in air on exposure to light, and phosphorescence of substances in a vacuum under the influence of the electric discharge, are of the same nature—viz., a response on the part of the substances to the operation of radiant energy propagated after the manner of light in undulations of short length. These undulations proceed from the electrode, and to them the gas in the tube responds, giving rise to the visible light in the gas. To this light some phosphorescent bodies respond, but others require to be affected by the very short undulations to which air is opaque. Such substances therefore only phosphoresce in high vacua. These conclusions are based on experiments made with a "jar spark" in air acting upon phosphorescent substances placed in the appropriate foci of a quartz lens; on the study of the behaviour of such substances outside a vacuum tube provided with a quartz window, and also on their behaviour inside the vacuum tube. The results of a very large number of experiments seem to indicate a close connection between the phenomena of phosphorescence of air and in a vacuum, broken only when the opacity of quartz to some undulations and of air to others interferes.

Electric Lighting in Calcutta.—Owing to a combination of favourable circumstances, not the least of which are its comparative cheapness, its immunity from accidents, and the reduced rates at which insurance companies will accept risks on factories, mills, etc., where electricity is used as a luminant power, electric lighting has acquired great popularity and is making rapid progress towards its general adoption in the near future for such purposes, says the *Indian Engineer*. We are therefore glad to notice two instances in which the installation has been successfully carried out. One is at the Calcutta Flour Mills Company, Limited, Narkaldanga, and consists of one 2½ nominal horse-power vertical Hornsby engine, which has a separate steam supply from either or both of the boilers. This engine drives a Crompton compound dynamo of a capacity of 758 lamps. A switch is provided on each floor of the mill and in each room in the bungalow. The wiring is carried out with Henley's cable, having an insulation resistance of 2,000 megohms per mile. The second installation has been carried out by the Oriental Telephone and Electric Company, Limited. This company opened an electric light department in Calcutta some three months ago, and this is their first installation. It has been carried out at the roller flour mills of Messrs. A. C. Mookerjee a Narkaldanga. The dynamo, a 60-light machine, is run from a countershaft, and is fixed on the first floor of the mill inside a small dust-proof room, in which are also fixed the switchboard, testing instruments, etc. This company are about to move into new premises now being built. They also intend putting down a special plant for the repairing of electrical machinery, cables, etc., and will have a dynamo running for the charging of accumulators, testing other dynamos, motors, etc.

The Government and Telepheny.—We referred to this matter last week in our "Notes," and in connection therewith Captain Bagot, in the House of Commons, has asked the Postmaster-General whether an agreement between the Post Office and the National Telephone Company had been in preparation for two years, and whether, in view of the fact that he had stated on various occasions during the last year that the agreement would be shortly laid before the House of Commons, he could now state definitely before what date the agreement would be produced. The hon. member further asked the right hon. gentleman whether he was aware that the effect of the long delay in concluding the agreement and the refusal of the Post Office in the meantime to grant licenses to municipalities had been to enable the National Telephone Company to increase their monopoly and place themselves in a better position than those municipalities which wish to obtain licenses, and whether he would state how many applications for local licenses from municipalities had been received since it was decided to purchase the trunk lines. Mr. A. C. Morton had a similar question on the paper. Mr. Henniker Heaton asked whether the Postmaster-General would take care that any agreement between himself and the National Telephone Company should provide that in the event of the purchase by the State of the company's property only the market value of the stock and plant actually belonging to the company should be paid as consideration money,

Digitized by Google

without taking into account prospective profits, or any claim for goodwill, or any similar claim. Mr. A. Morley said: "Since I answered a question on this subject on April 30 last further points of considerable complexity have arisen in connection with the settlement of the details of the agreement. While I very much regret the delay which has occurred—a delay which is in no respect due to any absence of effort on my part to bring it to a successful conclusion—I cannot think that it has enabled the National Telephone Company either to increase their monopoly or to place themselves in a better position. In fact, the hon. member for the Southern Division of Westmoreland appears to forget that the National Telephone Company only enjoy a temporary license which terminates in 1911, and that every month that passes must therefore have the effect of reducing the value of their goodwill in the business. I hope the hon. member will not press me to answer the latter part of his question, as I do not think it would be desirable in the public interest to reply to it at the present moment. With reference to the question of the hon. member for Canterbury, I must point out that the agreement now being negotiated is simply intended to give effect to the arrangement made by the late Government for the purchase of the company's trunk wires—an arrangement which did not contemplate any interference with the general conditions of the expiring license."

North of England Institute of Mining Engineers. On Friday last the members visited Greenside Mines, Patterdale, where they were received by Mr. W. H. Borlase, who read a paper, giving the history and description of the Greenside silver-lead mine, in which the process of working was described, and the author mentioned that some time ago more power was required, and the question arose of compressed air *versus* electricity. Electricity was decided upon, and a turbine dynamo station erected. The water for the turbine is taken at an elevation of 1,750ft. above sea-level, and flows through an open watercourse, 1¼ miles in length, to a wooden tank, from which it is conveyed down the hillside for a distance of 1,080ft. in cast-iron pipes 15in. in diameter. The fall at the station is equivalent to a vertical head of 400ft., and the effective horse-power is about 200. The electric current is conveyed by two bare copper conductors on poles for three-fourths of a mile, while it enters the mine at an elevation of 1,600ft. above sea-level. The conductors from this point are insulated and covered with lead. About three-fourths of a mile into the mine, and down through No. 1 shaft, or 1½ miles from the dynamo, a 9-h.p. series-wound motor is worked, winding the stuff from a pair of sinkers. Further into the mine another quarter of a mile, and down through No. 2 shaft to the 360ft. level or bottom of the mine, is fixed another 9-h.p. motor, working a three-throw pump forcing the whole of the water in the mine below the Lucy Tongue level up to that level 360ft. high. About midway between No. 1 and No. 2 shafts is fixed a transformer, which reduces the pressure from 600 volts to 250 volts for the purpose of working an electric locomotive in the lowest day-level through which runs the water used by the two hydraulic engines. The locomotive runs with a train of 12 wagons, the total weight when loaded being 18 tons (exclusive of itself), and it does the work with the greatest ease over gradients in places of as much as 1 in 20 and in 24. The conductors in this day-level are phosphor bronze wire, and the current is fed to the locomotive by four contact pulleys. The difficulties encountered in fixing this plant and wiring the level can only be appreciated by the practical miner. The curves are so numerous that the train occupies three and four of them at a time in places. The gauge of the railway is 22in., width of locomotive 32in. over all, and height 46in. The engine-rooms, caging stations at the different levels, and shaft tops are lighted by six 100-volt 16-c.p. lamps, wired in series. The adoption of electric power has enabled the mine to be worked with six horses less underground, and effected considerable saving in other ways. The cost of maintenance since December, 1891, including accidental breakages and wearing, renewals, brushes, etc., has not exceeded £25, which speaks for itself when taking into account that no professional electrician is employed on the staff. The turbine dynamo station and offices outside are in communication with the chief stations inside the mine by telephone.

The Niagara Power Scheme.—A representative of the *Pall Mall Gazette* has interviewed Prof. G. Forbes in regard to the Niagara scheme for the electrical transmission of power. The professor stated that the company hope to have the electrical plant in operation by August or September. The only thing they are waiting for is the completion of the long vertical shaft, and when that is put into position the dynamos will be laid down. The pit for the turbines is 150ft. long, 40ft. wide, and 200ft. deep. At the bottom of this three turbines have been placed in position, each of 5,000 h.p. The power company have limited themselves in their charter to 200,000 h.p. on the American side, and are prepared, when the demand arises, to sink a second tunnel; but they are already occupied with plans, drawn up by Prof. Unwin, for developing a power station on the Canadian side of the river which might be got up to 250,000 h.p. This will be connected electrically with the station just completed, and the two will be able to serve a very large district. The distance included in the company's radius of influence depends on the electric pressure used, and on the way the conductors are laid. For 100 miles round they will be able, the professor stated, to supply power cheaper than it can possibly be produced by steam. In Buffalo, 15 miles away, where they expect to find the bulk of their demand at first, and where coal is extremely cheap—something like 1½dol. a ton—the cost of electrical transmission from Niagara in enormously less. The industries of Buffalo, at the present time, absorb about 60,000 h.p., and of this 10,000 h.p. is required by the electric lighting and electric street-car companies, both of which, he observed, will be their customers. There had been a considerable demand for power in advance. The Niagara Falls Paper Mills—the largest in the world—are taking water power from the canal and discharging into the company's tunnel; the Pittsburg Reduction Company, who hold the sole rights in America for the electrical preparation of aluminium, will be very large users of the supply. There are any number of millowners waiting to set up works as soon as the scheme starts, and requests for power come in from places as far distant as Albany — 350 miles away on the Hudson River. With regard to the alternators, it was stated that "these alternators are the outcome of an enormous amount of experiment and enquiry; they were made to my plans by the Westinghouse Company, of America. The important feature about them is their being simple, two-phase alternators." Dealing with the question of pressure, it was mentioned that the company will generate energy at 2,000 volts, and supply in the neighbourhood at that pressure, using transformers at the different works, if necessary. For distant transmission they have erected a transformer-house across the canal, connected by a solid masonry bridge and covered way, where they will transform the pressure to something like 10,000 volts. The works will have cost altogether by the time the supply begins from £600,000 to £800,000.

ELECTRIC LIGHT AND TRACTION BEFORE THE ASSOCIATION OF MUNICIPAL ENGINEERS.

THE ANNUAL MEETING.

The Association of Municipal and County Engineers celebrated its coming of age last week in the hall of the Institution of Civil Engineers, where the first gathering of the society took place 21 years ago. There are now some 600 members belonging to the association, and a large number was present at the assembly on Thursday, Friday, and Saturday last.

Mr. A. M. FOWLER (the new president), in the course of his inaugural address, said: The great benefits which have recently accrued from the time and thought given by business men in town councils to municipal matters, has resulted in corporations rearranging their stock and borrowing capital for lengthy periods, in some cases for as long as 60 years, at the rate of, in many cases, under 3 per cent., and also by making the stock negotiable. These debts have not been entirely incurred directly for sanitary works proper, although the money is being expended with a view to the improvement of the public health, as in the case of acquiring waterworks, gasworks, tramways, hydraulic power, electric lighting, etc. All such undertakings, which formerly were in the hands of private companies, may now be said to be transferred to municipal authorities, and show in the capital account substantial assets, whilst the benefits derived by the ratepayers are considerable, not only on the ground of convenience and public health, but also more economical. In fact, the profits on gas, water, and tramways in some towns go far to pay the cost of public improvements: as in the case of Salford, which, during the time I acted as engineer, by laying down the tramways in pursuance of its own parliamentary powers, obtained a rental of 10¼ per cent., whilst Newcastle, in like manner, obtained 6¼ per cent., the only obligation being to keep the road in repair; whilst the new paving, sometimes of granite, was included in the capital account on which the interest was charged, thus bringing in many thousands of pounds per annum. Many towns have availed themselves of the powers offered by Parliament for providing electric lighting, and this is fast coming into universal adoption for private houses, the only drawback at present being the expense in providing the necessary motive power to bring it in closer competition with the cost of gaslight. This is, however, being daily reduced for small concerns by the introduction of Dowson's gas-engines and plant, and the application of anthracite coal, which is less costly than ordinary coal gas. This plant has now been running engines for some time with an expenditure of not more than 1¼lb. of fuel per indicated horse-power. Oil-engines are now also worked at a fraction less than one halfpenny per hour per horse-power. It is with hope, therefore, that the motive power for working dynamos may at no distant date be reduced in cost.

Among the various papers presented were two dealing with electric lighting and electric traction. The first is given below:

The Bradford Corporation Electricity Supply, with the Results of Four Years' Working.

BY JAMES N. SHOOLBRED, B.A., M.I.C.E.

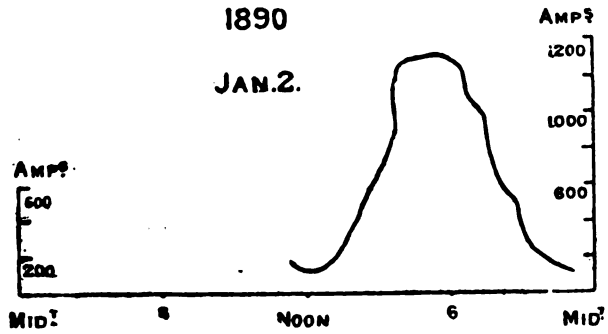
It is just 15 years since, at the annual meeting of this association in 1879, the author had the privilege of reading his paper on "Electric Lighting and its Application to Public Illumination by Municipal and other Bodies." Appended to that paper was the Parliamentary "Report," then just issued, "of the Select Committee of the House of Commons upon Lighting by Electricity"; the first of that series of enquiries by both Houses of Parliament on the subject of electrical energy, and which was presided over by the late Right Hon. Edward Stanhope. Much progress, indeed almost beyond expectation, has been made during the past 15 years in the science, as well as in the application, of electricity to industrial purposes. One short extract from the report of the above-named committee will suffice to show this: "Your committee, however, are not in a position to make recommendations for conditions, which may hereafter ar but at present do not exist, as to the distribution of elec currents for lighting private houses from a central source o power. . . But at the present time your committee do no consider that any further specific recommendation is necessar than that the local authorities should have full powers to use the electric light for purposes of public illumination, and that the Legislature should show its willingness, when the demand arises, to give all reasonable powers for the ful development of electricity as a source of power and light."

The answer to these remarks may be said to rest, and very appropriately so, in the paper which is about to be read to the Association of Municipal Engineers. For, on behalf of those local authorities to whom the Legislature had been willing "to give all reasonable powers for the full development of electricity as a source of power and light," it says: "The demand which the committee foresaw having arisen, and the Legislature having entrusted us with the desired powers, it therefore behoves us to present you with the actual results of the first four years' working of the pioneer of our municipal undertakings—that of the Corporation of Bradford—and to whom all honour is due to the lead which they have taken in this matter." This period at Bradford it will readily be understood by the meeting treats of a most important time, of early trials, and of much anxiety for those upon whom the responsibility lay. It also represents a completed term in itself; being the first chapter, that of the two-wire period, in the history of the Bradford electricity works. With the current year the second chapter, that of the three-wire system, has commenced, this latter development, as well as others still to follow, having been foreseen and duly provided for at the time when the installation was originally laid down, as was pointed out to the Corporation about 12 months ago by Lord Kelvin, P.R.S., when considering the entire question of the supply of electrical energy, and when further stating that they had acted rightly in adopting the present system at the commencement of their undertaking.

The supply of electrical energy (continuous current at low pressure), inaugurated on September 20, 1889, was intended for all purposes to which the continuous current is applicable—such as light, power (including tramways), and the many chemical and other industrial applications which occur in a manufacturing town like Bradford. The supply was confined at first to the central portion of the borough—where are to be found the best shops, some hotels, and other large buildings, such as the Town Hall, the public markets, theatres, and other places of entertainment. The district supplied extends chiefly to the north and to the west of the central generating station in Bolton-road, to a distance in each direction of three-quarters of a mile. The electrical energy is distributed by means of underground armoured cables, laid in the ground itself, chiefly under the footwalks on each side of the street, without the intervention of any culvert, and with the connecting and other junction boxes filled up solid; thus avoiding any chances of accumulations of water or of gases such as, in other towns, have of late led to several serious accidents. From the central station a series of feeding mains, radiating in different directions, deliver the current to the distributing network, where it is maintained at a uniform pressure of 115 volts; a "standard pressure," which is found to adapt itself very fairly to the various applications of a town supply of electrical energy. The following steam generating and electrical plant has been erected at the central station; four steel Lancashire boilers, each of 180 h.p., working at 140lb. steam pressure per square inch. The steam-engines, compound, non-condensing, are of the inverted vertical type, each engine driving directly a dynamo, which is placed on the same bed-plate with it. All the engines are of the single-acting, closed Willans type; with one exception, which is of the ordinary double-acting marine engine class. This last was obtained at the commencement, but as the subsequent comparative working of the two types of engine showed that the closed type was better suited to the requirements of this station, all the later engines have been of the last named single-acting make. The total power of the steam-engines is about 1,600 i.h.p.; and the engines occur in the following sizes—viz., 80 i.h.p., 150 i.h.p., and 300 i.h.p. It should be noted that it is by the judicious use

Digitized by Google

of several different sizes of engine, that the difficulty of meeting the great, and sometimes sudden, changes in the demand for steam power which occur in a supply of artificial illumination, can be successfully and economically got over. It seems almost needless here to point out the advantage of having the dynamos directly driven by the steam-engines, as against having belts or ropes intervening between them, especially after the clear statements as to the losses of the latter arrangement in Mr. R. E. Crompton's paper on the "Cost of Electrical Energy," communicated to the Institution of Electrical Engineers, and in the discussion thereon. The dynamos are shunt wound, and their total ampere output available at the consumers' terminals is about 5,000 amperes. A very valuable adjunct to this generating plant during the last three years has been a set of storage cells of Crompton-Howell make, which, though only of a moderate capacity, has rendered most important assistance in carrying on the supply uninterruptedly through



Ampere Output Curve.

the 24 hours. The time during which the generating plant was enabled to be stopped, and the supply carried on unaided by the storage battery, amounted, out of the 24 hours, in 1891, on an average to 12 hours, or 50 per cent., and in 1892, to 10½ hours, or about 45 per cent.; while in 1893, owing to the increasing demands, it was only five hours, or about 21 per cent. of the entire time.

The importance of the economy thus effected in the working can be more easily realised by an examination of the daily ampere output curves of the station. Some of these prepared from information kindly afforded to the author by the Corporation accompany this paper. Horizontally each diagram represents the 24 hours from midnight to midnight, while, vertically, the total amount of the supply in amperes throughout the same period is indicated by the varying height of the curve line above the horizontal datum. The full line of the curve sets forth the work done by the dynamos, while the broken line shows the part taken by the storage battery, both discharging during the time the generating plant is stopped, as also while being charged by the dynamos. It will be seen from these diagrams, that from shortly before midnight until, at least, six o'clock on the next morning, or perhaps until noon, or after, the generating plant was always stopped; the result being a very considerable saving in coal and wages to the staff, and one which could not have taken place had the alternating system been in use, as no cessation in the working of the generating plant is possible therewith.

In order to indicate the progressive working of the undertaking, there is appended to this paper a tabular statement compiled from the half-yearly electricity accounts, issued by the Bradford Corporation during the four years 1890 to 1893. From these tables, the more fully to illustrate the progress which has been made, the author has been able to prepare a diagram (No. 1), which shows graphically the half-yearly amounts of (*a*) the working expenses, of (*b*) the gross receipts, of (*c*) the units sold, and of (*d*) the working cost per unit. From this diagram it will be seen that during the last two years, at least, the working expenses have been on an average only 50 per cent. of the gross receipts, and the working cost per unit 2½d. The selling price has been 5d. per unit throughout

Digitized by Google

this period, and this low rate has this year been reduced, though for power only, to 3½d. per unit.

It may be of interest here to remark that already a fair and an increasing source of the day revenue has arisen in the sale of current for hoists, and for other small engines. Indeed, by the time when the Corporation tramways come to be worked by electricity from the central station, as the question of the relative expenditure upon wages, coal, and water is of special interest. The money values which have been paid, three-monthly, during the four years 1890-93 upon each of these items have been arranged upon a diagram (No. 2). By comparing this with No. 1 diagram, it is instructive to note that the amounts expended upon these matters have not increased in the same rate as

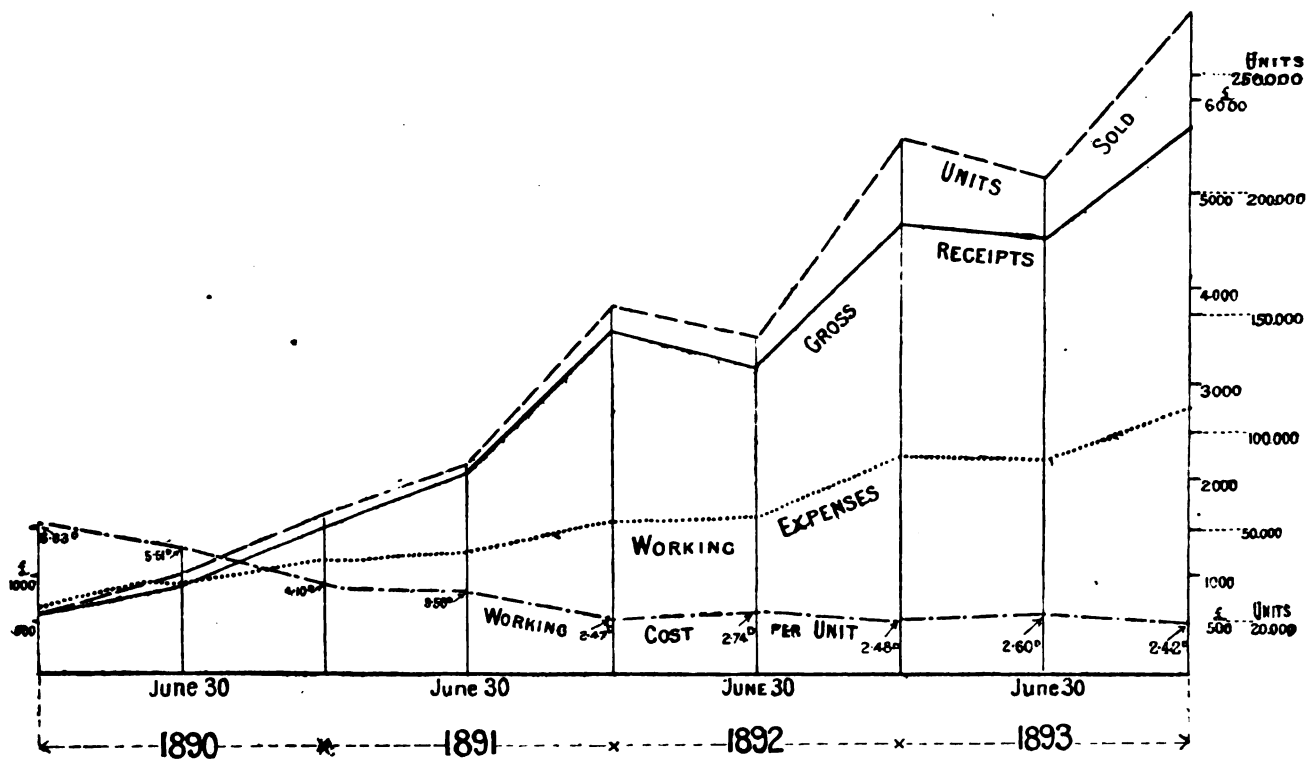

DIAGRAM No. 1.—Graphic Representation of Working Expenses, Gross Receipts, Units Sold, and Working Cost per Unit.

a series of experiments has shown to be feasible, the demand under the head of motive power will be considerable. Already the superiority of the "continuous" form of current for these applications (motive power, storage, etc.) is forcing itself upon the advocates of alternating currents, who now begin to perceive the value of some of the financial advantages to be derived therefrom, and which they has the output obtained. Or, in other words, that the services of the staff, as well as the steam-producing properties of the plant, have both been utilised to a greater extent than was the case in the earlier stages of the undertaking. The financial results of the four years' working of this electric undertaking, as shown by the half-yearly revenue, the interest and sinking fund, the profit

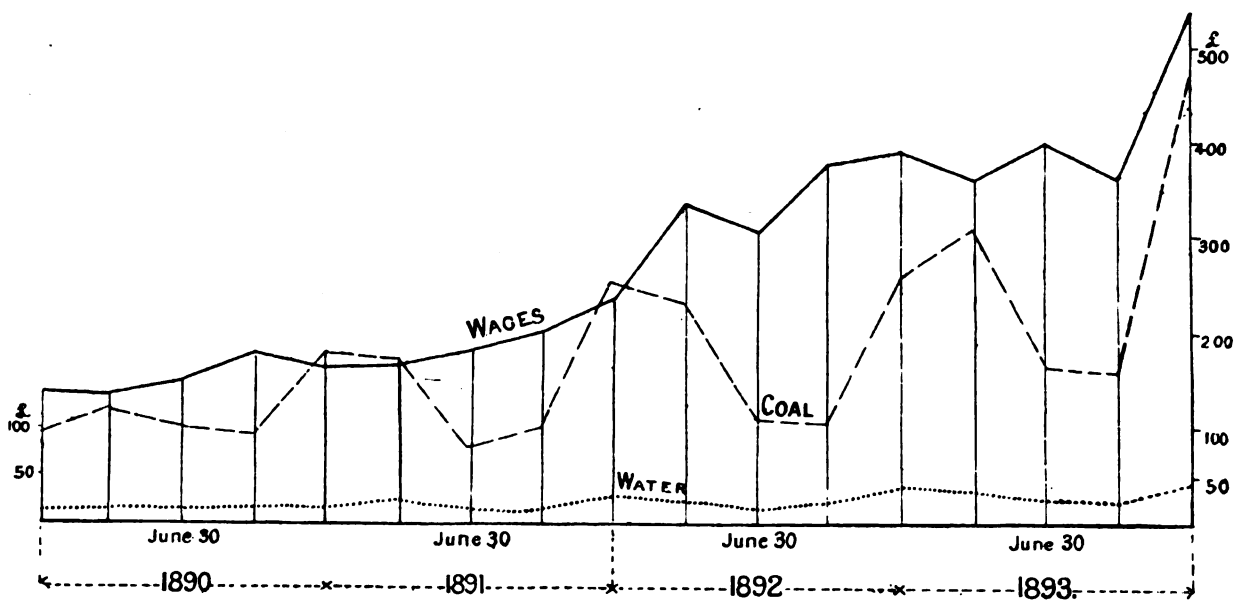

DIAGRAM No. 2.—Graphic Representation of Quarterly Expenditure upon Wages, Coal, and Water.

have hitherto thrown away; not to speak of the difficulties of distribution, in the conductors and in other ways, which the use of the "alternating" current brings with it. These objections they would now seek to get over by "redressing" the current, that is, by reconverting from an "alternating" back again into a "continuous" one. But why ever have departed from the original "continuous" form, with which they were bound to start? To engineers and loss and the capital expenditure accounts respectively, of the Bradford Corporation, may be put briefly in the following terms: not merely have the working expenses been met from the commencement, but also the interest on the municipal loan, together with the proportionate annual contribution towards the sinking fund for the repayment of that loan, have been paid, even during the construction of the works. Of course, during the early days the receipts

Digitized by Google

did not suffice to meet these two last items, amounting in themselves to nearly 7 per cent. on the capital in use; so rapidly, however, has the demand for electrical energy grown in Bradford, that the whole of this "leeway" has been made up (as may be seen from the profit and loss account) and a balance of profit left at the end of 1892, or in three years after the commencement of the supply; while by the end of 1893 a sum of over £2,000 had been placed to the clear profit of the undertaking. In fact, for the last two years, at least, the balance of gross profit over ordinary working expenses has amounted to a return of about 10 per cent. upon the capital then expended—a result which is most exceptional in the history of municipal enterprises, considering the short period during which the present undertaking has been in operation.

It may probably be of further interest to the meeting if some comparison could be presented between the "rates per unit" which have been reached at the Bradford electric undertaking, and those which occur at some other similar ones which have been longest working in this country. For this purpose the returns to the Board of Trade for 1893 would offer the most reliable basis, while limiting the selection to those works which have been in operation for at least three years, since it would be manifestly unfair to the more recently established ones to compare their economical results while they are still in what may be termed their initial stage.

COMPARATIVE "RATES PER UNIT" IN 1893.

	Capital expended.	Working cost.	Sale price.
Continuous Low Pressure.	s. d.	d.	d.
Bradford	2 4	2·5	5
Kensington and Knightsbridge	4 10	4·2	7
Liverpool	4 9	2·9	7
St. James's and Pall Mall	3 8	3·7	6
Westminster	4 5	4·0	6
Alternating High Pressure.			
Eastbourne	6 0	5·2	9
House-to-House (West Kensington)	4 3	5·2	8
Metropolitan	4 2*	4·6*	6
Newcastle District (Parsons) †	2 4	2·6	4½
Newcastle-on-Tyne (Brush) †	2 6	2·9	4½

* This figure can only be approximate; no return having been made to the Board of Trade as to the number of units sold.

† These two undertakings ought, for the purpose of comparison, to be taken as one.

Ten well-known undertakings have been selected as fulfilling the above conditions; five of these are working on the "continuous" current system at "low pressure," and provided with storage batteries, and the remainder on that of the "alternating" current at "high pressure," and, of course, without storage. The result of the above comparison shows that the Bradford undertaking works as cheaply as the Newcastle ones, where coal is very cheap, and more economically than any of the other stations in England.

From the facts which have been detailed in this paper it is evident that the ratepayers of Bradford have no cause to regret, financially, the results of the action which their Corporation have taken in providing them with the advantages of a supply of electrical energy. It must likewise be a source of satisfaction to feel that this has been done without exposing the inhabitants to those serious risks to life which occur with the "high-pressure" current, and which have already led to fatal accidents in other towns. Results such as are described in the paper are remarkable, and redound very greatly to the credit of those Corporation officials at Bradford who have especial charge of the working and management of the undertaking—more especially of the late chairman (only recently resigned) Alderman F. Priestman, J.P.; of the worthy and respected town clerk, Mr. W. T. McGowen; and more particularly of the resident managing engineer, Mr. S. W. Baynes. The author can fully appreciate the thorough business qualities of the alderman, and the kindly assistance which he himself has ever received at his hands (while acting as electrical engineer to the Corporation) in the design and during the construction of the present works, as well as in the earlier years which preceded their construction; while as regards Mr. Baynes, he has had even a longer acquaintance of him, extending—electrically at least—into almost prehistoric times: he can therefore fully appreciate the care, diligence, and attention to the smallest details which have always characterised Mr. Baynes's management, and which have so largely conduced to the working results described in the paper. No attempt, however, to chronicle the history of electricity in Bradford would be complete without reference to the ever courteous and energetic town clerk, as most probably, or rather most certainly, had it not been for his unceasing exertions in favour of electric lighting during the past dozen years, the results which have been described in the paper would not have had any existence, at least, for some years to come.

In conclusion, the author must also thank the Corporation for their having so kindly placed at his disposal, and so unreservedly, the large amount of information which has enabled him to place before the meeting the principal facts contained in this description of the results of the four years' working of the Bradford Corporation electricity supply.

The second paper, by Mr. R. Hammond, on "Electric Street Tramways," was taken as read. We shall give an abstract of this paper in our next issue, together with a report of the discussion on the two papers.

THE GAS AND ELECTRICITY SUPPLY OF BLACKPOOL.*

BY WILLIAM CHEW, M.I.E.E., BLACKPOOL.

(Concluded from page 730.)

I will now describe the new electric works as fully as possible that we may be acquainted with the class of competitor the new agent is likely to assume. Wherever electricity works are first commenced for a general supply, it is difficult to forecast precisely the amount of light immediately required; but in Blackpool there are exceptional circumstances that cause a very large demand in proportion to the size of the town, from the existence therein of so many places of public resort which vie with one another. An approximate estimate was based on the requirements of these places, and a 200-unit incandescent lamp plant, with an 82-unit arc lamp plant, was fixed upon. Acting on this, electrical contractors were invited to submit estimates and designs, with the result that the works have been erected at a cost of £30,000. It was thought a large outlay; but it was estimated that if only one-half was immediately put in operation, there would be little loss, whilst if the output should ever reach the capacity of the plant, then the profits would fast accrue, owing to certain fixed charges being almost stationary. This is the universal opinion of all electricians, even those that have half a million of capital laid out. The system adopted was that known as the alternate-current high-pressure system, with a converter to low pressure fixed in each consumer's premises; and for public lighting, a separate plant on the direct-current high-pressure series system.

The works, which adjoin the gasworks and their sidings, consist of a boiler-house 123ft. by 68ft., and a producer-house 123ft. by 55ft. There are three Lancashire boilers, 28ft. by 7ft., fitted with mechanical stokers, and apparatus intended for the consumption of smoke.

The producing plant for incandescent lamps consists of

		Volt.	Amp.	Rev. per min.

the driving power for these being imparted by cotton ropes.

The Arc Light Plant.

No. 1 dynamo	27½	units, maintaining	55	arc lamps of	10 amperes.
,,	27½	,,	55	,,	,,
,,	27½	,,	55	,,	,,
Total ...	82½	units ,,	165	arcs.	

These machines run at the rate of 800 revolutions per minute, and are each driven by a 60-i.h.p. engine, the same type as the others.

This constitutes the plant of the producer-house, the current being taken from each machine to a distributing board for combining or by-passing the various circuits required. A testing resistance equal to the output of the largest producer is provided

* Abstract of paper read before the Incorporated Gas Institute.

Digitized by Google

to be used when required. A suitable overhead crane for repairs is fixed to travel on the walls, and beyond several small testing instruments for measurement of current and pressure regulators, this constitutes the whole of the generating plant. In the distribution of the current great care has to be exercised in apportioning the sizes of the mains, owing to the cost of copper contained in them, and the loss of pressure if at all too small; for with too small leads it is easy to expend 50 per cent. of the production in overcoming the resistance. The distributing mains are laid in 3in. and 4in. diameter T and B pipes on each side of the streets, in straight lines, with a brick eye at easy distances. The cables are stranded copper wire, insulated with vulcanised indiarubber, and threaded into the pipes. These were laid without attempting to keep them watertight, as the quality of the insulating material was so good. Being laid in straight lines, about 18in. deep, they necessarily overlap the gas-mains; and are liable to accumulate gas therein owing to disturbance of the earth in laying them. The effect of this will probably be seen later on, when the precise nature of the disturbance has been forgotten. The main leads are taken along some of the principal streets, at 2,000 volts pressure, and to consumers' houses, where the converters are fixed to yield 100 volts pressure to feed their lamps. A two-night test at one consumer's premises shows the effective pressure obtained therein.

Time.	Pressure, volts.	Time.	Pressure, volts.
7.10	108	7.25	111
7.22	104	7.40	107
7.25	94	7.41	94
7.28	96	7.47	99
7.30	94	7.50	96½
7.40	93½	7.58	97½
7.45	94	8.0	100
7.51	96	8.1	96½
8.0	94½	8.13	96
		8.30	96½

From this it will be perceived how difficult it must be to keep at 100 volts steadily if under penalties. There have been about 8,000 yards of mains laid containing 20 lineal miles of wire; and on these are fixed about 60 consumers, several being very large ones. The public lighting is carried out on a brilliant scale on the Marine Parade, the lamps being about 50 yards apart and 25ft. high. They each use half a unit of current per hour, and are known as 2,000 nominal candle-power. In the main streets 25 others are being erected. These displace 200 gas lights. The works were put in operation on August 1, 1893, and the cost was as follows:

Land (rented)		
Buildings	£8,008 = 26½	per cent.
Apparatus	10,500 = 25	,,
Mains and services	7,000 = 23½	,,
Lamps and posts	4,000 = 13½	,,
Meters, etc.	500 = 1½	,,
Total	£30,008 = 100	,,

The output of the plant is calculated at 150,000 units per annum, or = 4s. per unit made. In order to push the new light, the usual pamphlet was issued setting forth the hygienic capacity of the light in comparison with gas, and a few rules as to insulation requirements of consumers' leads. Canvassing consumers is strongly pursued also. The scale of charges for current are scheduled as follows: incandescent lamps by meter at 6d. per unit, with a discount ranging from 5 to 25 per cent.; for private arc lighting, 2d. per hour for half-unit lamp equals 4d. per unit, less 10 per cent. discount; promenade and town lighting at actual cost of current, plus maintenance. As a result of starting the plant, the guaranteed customers to the extent of about 60 were quickly supplied, one of these taking alone fully one-third of the entire private consumption. The Corporation themselves are also large users, coming in for nearly half the total output, which for the eight months previous to March 25 was:

Produced at works for private use	55,600 units.
,, ,, public lamps (only half lit during winter)	22,560 ,,
Total	78,160 ,,

The works are now employed at their maximum output, the reserve plant being encroached upon thus:

Available output in one hour = 200 units	
Actually in use	195 ,,
Balance (reserve)	5 units, or 2½ per cent.
Arc Plant.	
Available	155 arcs
Actually used	140 ,,
Reserve	15 arcs, or 10 per cent.

The following weekly output from the works will give an idea of the extent of the lighting since the commencement (September 1, 1893, to March 1, 1894).

SCHEDULE OF OUTPUT PER WEEK FROM SEPTEMBER 1, 1893.

As there are several more customers ready to come on, the extensions of the mains to supply them have already been put in hand, and a temporary plant has been put down till the permanent one can be erected. This new outlay will raise the capital to about £50,000, and the incandescent capacity will then be raised from 200 units to 450 units per hour.

One result peculiar to new electrical works is that the cheap high-tension distributing pioneer system of separate transformers has in six months to be replaced with a new low-tension system of distribution in the centre of supply by means of half-a-dozen transformers placed in the streets. In this way the difficulties attending the pioneer work will be reduced, as all house transformers will be abandoned where this system prevails. This is the second step towards having a central transformer station in the middle of the town where the future current will no doubt be distributed from, forming what is known to gas engineers as a town governor-house.

The result of the first half-year's working can hardly be taken as a standard of future costs, the plant being partly in the hands of the electrical contractors, so that many items chargeable will consequently not appear. Besides this increased output for longer periods is expected from the plant hereafter, which should tend to reduce the comparative costs. The total output to March 25 has been:

August 1 to December	43,867	units
December to March 25	34,359	,,
Total	78,226	,,
		Per unit.
The working cost of producing this has been	£1,774	= 5·44d.
Proportion of interest only chargeable for this period	629	= 1·93
	£2,403	= 7·37d.
Add if the whole interest and sinking fund for eight months had been chargeable = £1,150 at 5½ per cent.	521	= 1·60
Total	£2,924	= 8·97d.

The cost per unit sold is rather difficult to apportion in this necessarily experimental period, owing to waste caused by trials of plant, and which are recorded in the output only, and might be misleading. The loss on distributing of the incandescent system alone is about 25 per cent. of the output; that for the arcs being almost negligible, owing to the mains being in use during the time of actual lighting only. This working cost is undoubtedly a high figure in comparison with the selling price; but as the plant has reached its maximum capacity, and the

Digitized by Google

working cost has had the advantage of freedom from repairs, rates, and depreciation, it is clear that any reduction on cost must be in the direction of longer average daily loads, coupled with sundry economies, and the very doubtful advantage of a larger station. I have not given a detailed cost of the eight months' working, and think it more reliable to give later details now we are in fair working order, as being more accurate.

From these working costs it is clear, in comparing week No. 3 with Nos. 1 and 2, that increased output for the heavy week caused decreased cost, and the net result for the year depends on the total output the plant is required to supply. It would require an average weekly output of 4,000 units, or 208,000 units per annum, to enable the works to sell electricity at 7d. per unit, which is the cost for week No. 3, when the whole plant was employed in producing 4,000 units. The amount earned at the prices charged, I think, need not concern you, as the cost price is the datum which ultimately fixes the commercial value in comparison with that of gas. Having placed before you the result of the working, it remains to be seen what has been the effect on the gas consumption during the period when 78,200 units of electricity were made, or a sale of about 58,000 units, being the equivalent of 5,800,000 cubic feet of gas. Well, during this period there were sold 180,000,000 cubic feet of gas, as against 150,000,000 the previous year, or an increase of about 30,000,000; our increase being five times the sale of electricity sold during the same period. To say that the effect was nil, is true in one respect only; for the output of gas has increased—owing partly to the addition of 300 new consumers, and partly to the more general use of gas. Had there been no electricity works, I think we should have had about another million cubic feet of gas sold. Taking 30 of the largest consumers of electricity, and comparing their accounts with the corresponding March quarter of 1893, we arrive at the relative effect on old consumers they take up :

	Cubic feet of gas.	Electricity.
30 consrs. used March qr., 1893	2,936,000 at 2s. 6d. = £366	— £366
30 ,, ,, ,, 1894	2,360,000 at 2s. 6d. = 295	£396 691
Less used.....	576,000 ... Less £72	

So that for the £72 worth less gas used, they took £396 worth of electricity, making the total lighting account £691, against £366—being an increase of £325 for the quarter in their accounts.

To summarise, it is evident that wherever electricity is used, less gas is burnt, and of the new customers hereafter it will take a share thereof. Electricity undoubtedly being a good light for business purposes, where its principal consumption lies, increased demand will continue until what is termed the "saturation" of the district is reached. The precise amount of this one can hardly foresee, and I think there is undoubtedly room for both systems in most towns—the extent varying with the peculiarities of each. Hereafter, with a dual supply in operation, the gas industry will have to be satisfied with less than the whole loaf, so to speak—a slice being taken off by electricity; so that the general effect will be that a gas company will be relieved to some extent of that great increase which has taken place in gas consumption yearly.

ACCUMULATOR CARS IN SYDNEY.

Some time ago the New South Wales Railway Commissioners, noting the improvements which have been effected in the accumulator system as applied to street traction, and also having in view the question of improving the tramway system, gave instructions for an experimental car to be constructed at the Randwick workshops. The car has been completed, and various trials have been given in order to demonstrate its suitability for use on the lines in Sydney.

The car is of the same pattern as the standard cars in general use, with the exception of the ends, which are rounded to allow room for the driver. The *New South Wales Railway Budget* states that the energy is contained in seven boxes of accumulators of the Planté type, as recently modified by Mr. Epstein. These are encased in the body of the car, and are capable of supplying 20 h.p for five hours' actual running, or a larger power for a proportionately less time. The motors, one on each bogie, are nominally of 25 h.p. each. They are of the latest type used on the large electric tramways in the United States, and are practically noiseless, the gear being protected by closed boxes containing oil. Electric lamps are fitted in the smoking and non-smoking compartments, and electric head-lights are used. A power brake has been specially designed for use with this car, worked by electricity, which distributes the brake pressure over all the eight wheels equally, and can be graduated with the greatest nicety. The driver stands with the general controlling and reversing handles on his left hand, and at his right the electric brake. A hand brake is also provided. The car is reversible, both ends being fitted in precisely the same manner. An ordinary car may be coupled on as a trailer.

The car was taken for a trial trip to Coogee on May 2, and in every way gave general satisfaction. The three commissioners entered the car at Bridge-street, and among the other passengers were Mr. G. Downe, locomotive superintendent; Mr. P. B. Elwell, electrical engineer; Mr. G. R. Cowdery, maintenance engineer; and Mr. J. Roberts, manager. This was not a test of speed in any way, the earlier portion of the journey being impeded by the presence of regular trams ahead, and the speed being altered at times to fully test the motors. It is believed that the car could do the journey in from 15 to 20 minutes, as it is stated that a speed of between 25 and 30 miles was easily put on during part of the journey. The car was taken round the loop at Coogee, and then back up the steep grades to Randwick. The run home brought the time of the round trip up to just an hour and a quarter, including stoppages, and the car seemed to have established a claim to be considered a success.

TO CORRESPONDENTS.

All Rights Reserved. *Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.*

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom.....	3s. 3d.	6s. 6d.	13s. 0d
Other Places.....	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THE VALUATION OF PATENTS.

Those who have unfortunately to attend courts of law, and to hear the various questions and answers and opinions on the value of a patent, must long since have wished that some guiding principle could be established in such valuations. If it be possible to do so, then some kind of agreement might be come to as to the value which can be justifiably placed upon a patent offered for sale, or purchased. We know of but one guiding line, and that, if followed, must allow of fairly wide divergences as to estimates. At the present time, however, the value of a patent is first what you can get for it, and the veriest rubbish may be appraised at hundreds of thousands of pounds if in the hands of good company promoters, while an intrinsically more valuable patent has to be sold for a mere song. It seems to us that the valuation of a patent ought to proceed upon some such line as is indicated by what follows. Take, in the first case, an improvement in some well-known piece of machinery. Admit the validity of the patent. In the ordinary course of business an income will be derived from that patent only by its being added to the whole or part of all new machines of the kind it is designed for, and also added to the whole or part of the machines already in use. Now, the life of the patent, so to speak, extends over a period of fourteen years—that being the time legally conferred upon the holder during which its manufacture is a monopoly. The holder has, in the first place, to make the nature of his improvement known, and, in the second place, to convince users of the machinery that it is an improvement. These things cost money. Further, as soon as the improvement becomes public knowledge, and is seen to be an improvement, there is a class of pickers and stealers which has for its object the improvement of improvements—the getting round of patents by modifications of detail, and too often some one or more of these modifiers succeed in achieving their object. The valuer, then, ought to be an expert who can to some extent gauge the possibility of getting round the original patent. Even if successful, the original patentee or his holder has to fight in the Courts for his rights, and then incur very heavy legal expenses. By some such exhaustive system of reasoning we ultimately come to the view that having a monopoly—having an article which possesses undoubted utility—it is possible during fourteen years to build up a considerable business in that article, and at the end of the fourteen years that business will have a marketable value called "goodwill," even when the possibilities of competition are considered. That marketable value of the business thus produced we deem the correct and proper value of the patent if valued at any time during its life. In our estimation the value of a patent in one sense depreciates every year of its existence, but, on the other hand, the goodwill for the business obtained by its means increases. This depreciation and increase should each year equally balance, so that from our point of view there is one constant amount standing in the

Digitized by Google

books of a firm or company giving this value of the patent. The amount is, except during the first and last years of the patent's existence, made up of two amounts—one entitled "value of patent," the other, "derived goodwill from the working of the patent." During the first year the total is put to "value of patent," during the last year to "goodwill." The value of a patent certainly does not lapse with its death at the Patent Office, unless, indeed, it is something which is in demand for fourteen years only, and has no permanent value. It certainly does in many cases enable a business to be made or improved, and that business goes on even after the patent has lapsed. Of course, the valuer of a patent on these lines must be something more than someone in the City, and must consider much beyond the necessities for a prospectus or the floating of a company.

Justice needs that both be heard."

EFFICIENCY OF ELECTRIC MOTORS.

SIR,—You may be interested to hear that a result as far as we know unparallelled, has recently been achieved by Messrs. Mavor and Coulson in motor construction. They have recently supplied us with a 500-watt Sayers motor, for 500 revolutions per minute, which weighs under 2cwt., and has an electrical efficiency of over 90 per cent. This is such an enormous advance on ordinary practice that we think it only due to our *confrères* who may be interested in motor design to state that we shall be pleased to put the machine at their disposal at any time for inspection or test.—Yours, etc.,

THE BATTERY AND MOTOR COMPANY.

London, June 23.

ELECTRIC LIGHT IN A WEST-END HOUSE.

The problem of suitably adapting valuable chandeliers and other such contrivances to the service of electric incandescent lamps is not by any means an easy one to solve, though the electrical engineer is continually being called upon to undertake the task. Amongst those who have had this experience may be mentioned the gentleman who was called in by Mr. John Murray, the well-known publisher, to supervise the conversion of some fittings for his house. These, when finished, were seen and admired by Mr. Burdett-Coutts, who at once requested the same engineer to undertake an installation of electric light in the Piccadilly mansion of the "benevolent Baroness," as she is often called. The work of replacing candles and oil lamps with incandescent lights has just been finished; and to mark the event, a select few of Press representatives were invited by the Baroness and Mr. Burdett-Coutts to inspect, on Monday evening last, the completed arrangements. The total number of lights installed reaches about 580, though many of these are of quite small candle-power. In the magnificent cut-glass lustres or chandeliers—at least a century old—suspended from the ballroom ceiling there are nearly a hundred 2½-c.p. lamps, together with 20 or more 16 c.p. distributed amongst them. The lamp wires are led along the glass stems in the usual way, being secured thereto by fine binding wire, and are covered over with silver foil so as to be almost invisible in any light. Specially made glass pillars, bulbous at the top, and beautifully cut in horizontal or diamond shaped patterns (to prevent light from the incandescent filament actually striking the eye) are used for the nozzles at points where formerly the wax candles were inserted, and the remaining lamps are placed inside the rings of cut-glass drops. Much of the artistic arrangement and grouping of the lights must be credited to Mr. Burdett-Coutts himself, who has indeed kept in view throughout the two principles of retaining and adapting the old fittings and also of hiding from sight the bare white-hot filament of each lamp. In the picture gallery a specially fine effect is obtained by means of diffused light from above through frosted ornamental glass skylights in the ceiling, on very much the same principle as that adopted in the House of Commons. Since in the daytime these skylights are depended upon for sufficient light, it was a somewhat difficult task to so place the electric lamps that they should not obscure the glass in any way, but this task has apparently been quite satisfactorily carried out. The lighting of individual pictures, as, for instance, in the dining-room, is very successful in some cases, but not so much in others. It would seem almost as though the arrangement of lighting must be modified as to amount and direction for each picture, and no hard-and-fast system of top and bottom or side lighting can give complete satisfaction. Taken as a whole, however, the installation is extremely effective, and does great credit to all those concerned.

The installation has been carried out by Messrs. Townsend and McIntyre, Brook-street, W., under the supervision of Mr. V. G. Middleton, the consulting engineer, of 3, Princes-mansions, Westminster, S.W. The elaborate fittings previously used in the house for wax candles, oil, etc., have been altered and adapted to the new method of illumination by Messrs. Perry and Co., of Grafton-street, W., from whose factory have also come the new fittings required.

AN ELECTRO-CHEMICAL METHOD OF OBSERVING ALTERNATING CURRENTS.

In a recent issue of the *Comptes Rendus*, Mr. R. Janet deals with this subject. He states that there are two factors in connection with alternating currents which are not always easy to measure—viz., frequency and difference of phase.

The author has devised a graphical method offering great facilities for making measurements. Over a recording metallic cylinder is placed a sheet of paper which has been soaked in a solution of ferro-cyanide of potassium and nitrate of ammonia. An iron or steel style is made to press against this paper. The cylinder and the style are then connected respectively to the two points across which it is necessary to study the periodic E.M.F. As the circuit has no self-induction, the current will be in phase with the E.M.F. If under these conditions the cylinder be rotated, periodic blue lines will be produced corresponding to the maximum values of the E.M.F.'s. By this method frequency can be very readily measured. For measuring the difference of phase between two E.M.F.'s of the same frequency, it is only necessary to record the two impressions side by side, and to measure the distance between the two maximum values. By this method it would be easy to measure the difference of phase between the primary and secondary currents and E.M.F.'s of a transformer. The author has found this method capable of being applied to many cases.

Experiments were made on currents obtained from Zipernowsky alternators at 110 volts. (1) Three points—A, B, C,—on the circuit were taken, and separated by non-inductive resistances consisting of incandescent lamps. The point B was connected with the cylinder, and A and C with two styles. Under these conditions two discontinuous lines were obtained; the maxima of one separating into two equal parts the intervals formed by the maxima of the other. (2) An inductive resistance was inserted in place of one of the above non-inductive resistances. The difference of phase was immediately changed. The maxima of the discontinuous line corresponding to the inductive resistance separated into two parts, the intervals of the maxima corresponding to the lamp resistance.

THE ANNUAL SHOW OF THE ROYAL AGRICULTURAL SOCIETY.

SOME OF THE EXHIBITS.

The fifty-fifth annual exhibition of this society was opened on Monday, at Cambridge, and will close this (Friday) evening. There is very little of interest to electrical engineers, but we give a summary of some of the principal engineering features of the show indirectly connected with electric lighting.

Great interest has been taken in the oil-engine competitions which were instituted by the society, and which concluded on Tuesday. The society offered in class 1 a first prize of £50, and a second of £25 for fixed oil-engines of from 4 b.h.p. to 8 b.h.p., and similar awards in class 2 for portable engines of from 9 b.h.p. to 16 b.h.p. The names of the competitors in the first class were: the Daimler Motor Syndicate, Limited, of 49, Leadenhall-street, E.C.; Weyman and Hitchcock, Limited, of Guildford; Samuelson and Co., Limited, of Banbury; the Campbell Gas-engine Company, Limited, of Halifax; the Britannia Company, of Colchester; Tolch and Co., of 146, Clerkenwell-road, E.C.; Fielding and Platt, of Gloucester; Holmes and Son, Limited, of Castle Hill, Norwich; Crossley Bros., Limited, of Openshaw, Manchester; Wells Bros., of Sandiacre, near Nottingham; Clarke, Chapman, and Co., Limited, of Gateshead-on-Tyne; and Richard Hornsby and Sons, Limited, of Grantham. In the second class the following firms competed: Weyman and Hitchcock, Limited; the Campbell Gas-engine Company, Limited; Clarke's Crank and Forge Company, Limited, of Lincoln; Fielding and Platt; Crossley Bros.; Clarke, Chapman, and Co., Limited; and Richard Hornsby and Sons, Limited.

At the close of the trials, Messrs. Hornsby and Sons were awarded the first prize of £50 for their fixed Hornsby-Akroyd oil engine of 8 b.h.p., and the first prize of £50 for their portable oil-engine of 12½ b.h.p. The second prize of £25 was awarded to Messrs. Crossley Bros., Limited, for their petroleum oil-engine of 6½ b.h.p., but the second award for the portable oil-engine has not been made.

Mr. E. S. Hindley, of Bourton, Dorset, exhibits a variety of his well-known types of vertical and horizontal engines, pumps, and band sawing machines.

The Britannia Company, of Colchester, and of 100 and 101, Houndsditch, London, exhibit the Britannia oil-engine, which works on the Otto cycle, and is made in sizes of from ½ h.p. upwards. The principal feature is the initial heating of the oil before mixing it with the air by means of the waste heat from the tube lamp, together with the vaporisation of the oil, and the further addition of air heated by the waste heat in the exhaust. The governing is effected by partially reducing the charge of oil to at least 50 per cent. of full power before cutting out a charge, thus making a steady-running engine. The engine is fitted with an automatic aid to starting, by which the pressure of compression is first removed altogether to give the charging stroke, then half compression to aid starting, and finally the working compression; this adjusts itself automatically without the man leaving the flywheel. Among other exhibits at this stand is an assortment of engineers' lathes, milling machines, shapers, etc.

Messrs. R. Hornsby and Sons, Limited, of Grantham, make a prominent display of oil and steam engines and agricultural implements generally. With regard to the oil-engines, the company show one of 8 b.h.p. This engine is capable of working with light or heavy oil of from ·800 to ·886 specific gravity, including ordinary petroleum lamp oil. The engine works with great economy without skilled attendance, and is suitable for estate works, electric lighting, and other purposes. A portable oil-engine, is also shown. It is of 12½ b.h.p. Various other oil-engines are likewise on view, and a portable steam-engine of 8 h.p.

Messrs. John Fowler and Co., of Leeds, exhibit, among other of their manufactures, one of their "Class A A" compound ploughing engines, of 12 nominal horse-power, fitted with their latest improved self-acting coiling gear and 450 yards of Fowler's "special quality" steel wire ploughing rope. More or less powerful engines are manufactured by the firm of a similar type—viz., of 20 h.p. (nominal) and 16 h.p. (nominal), also 7 h.p. and 8 h.p. (nominal).

Messrs. W. H. Willcox and Co., of 34 and 36, Southwark-street, London, S.E., show a collection of goods suitable for engineers, manufacturers, and users of steam and other motive power generally. The exhibits comprise their special engine and pump packings for pistons, valves, etc.; asbestos, indiarubber sheet; suction and delivery hoses for water barrels, pumps, etc.; new patent indiarubber hose and wire-bound hose; leather, cotton, and hair beltings; cylinder, lard, neatsfoot, and a variety of engine oils; boiler and engine fittings, and the Penberthy patent injector, besides gauges, cocks, valves, and lubricators.

Messrs. Tangyes, Limited, of Birmingham, are represented by a selection of gas-engines, steam-engines, pumps, etc. One of the gas-engines shown is connected to a pump and another drives a Siemens dynamo, supplying current to a number of lamps. The large engine exhibited by this firm is capable of developing 115 i.h.p. with ordinary town gas. Of the three types of steam-engines shown one is a horizontal engine fitted with Tangye-Johnson patent automatic cut-off gear, and has a 12in. cylinder and 24in. stroke. There is also a double-cylinder vertical steam-engine for confined spaces. Three sizes of the special steam-pump are exhibited, and the duplex type of pump is also shown.

Messrs. Drake and Gorham, of 66, Victoria-street, Westminster, make an attractive display of electric lighting at the stand of Messrs. Priestman Bros., Limited, of Hull, where the manner in which existing candelabra, old Moorish fittings, silver candlesticks, etc., can be utilised for use with the electric lighting is amply demonstrated. The firm have made a special study of installing the electric light with a view to giving the maximum of convenience and other advantages attaching to the system, and yet maintaining the same general effect as was formerly obtained with the wax candles and other soft and subdued lights. This system was the subject of much comment in connection with the successful electric light installation at Chatsworth for his Grace the Duke of Devonshire, and similar treatment has been carried out at Wynyard for the Marquis of Londonderry, Alnwick Castle for the Duke of Northumberland, and many other country seats. Were it not that the rooms are better lit than could be attained by the older systems, it would really be impossible for anyone entering the rooms to determine whether the light was electric or not, so effectually has all glare been removed by these special methods of shading, which have been from time to time developed by the firm. A special feature is made of a species of "Lotus" shade, which is made from paper in the form indicated, each petal being provided with a wire to maintain its position. These are made in delicately tinted shades which entirely obviate the unbecoming effect which has so often been attributed to the electric light. The imitation candles which are fixed in existing old candelabra have also been made a special study, with the result that it is impossible to separate the imitation candles from the best yellow wax. The firm also exhibit a D.P. accumulator, for which they hold the sole concession for the United Kingdom. This cell has been largely used for the past four years for supplying the current necessary after the engine has stopped. The chief feature in this cell is the low cost of up-keep which has been such a drawback in the past to the use of accumulators in country-house lighting. The dynamo from which the lamps on this stand are energised is of the E.C.C. type, giving 90 amperes at 135 volts, and it will shortly be laid down at The Rookery, Nantwich, for Baron von Schroeder.

Messrs. Priestman Bros., Limited, of Hull and London, exhibit their well-known oil-engines. These include a 20-h.p. double-cylinder horizontal engine, a 7-h.p. single-cylinder horizontal engine, a 2-h.p. single-cylinder horizontal engine and trolley specially designed for light agricultural purposes, and a 5-h.p. double-cylinder vertical marine oil-engine, with McGlasson's patent reversible propeller and shaft. Since the last Royal Agricultural Show various minor details have been improved upon which

Digitized by Google

experience has suggested. The company state that, notwithstanding the depressed state of trade, they are now busy running day and night with orders for engines ranging in sizes up to 70 h.p. The steadiness and regularity with which the Priestman oil-engine runs has led to a large sale for electric lighting purposes alone, and the firm have lately received instructions to supply engines for this purpose to the Royal Engineers, Mr. T. H. Ismay, Mr. C. B. Wilson, M.P., Prof. Herkomer, R.A., Dr. W. Paget Tomlinson, Rev. J. D. Parker, LL.D., and others. One of these engines is shown in operation, driving an E.C.C. dynamo giving 90 amperes at 135 volts, and energising a number of lamps installed by Messrs. Drake and Gorham, and to which reference is made in another column. A number of repeat orders have been received, and these alone prove the value of the engine. The marine type of engine has also met with success, and is now being made in sizes up to 70 h.p.

Messrs. J. and H. McLaren, of the Midland Engine Works, Leeds, exhibit a selection of traction engines, engines for agricultural purposes, and hand-force feed pumps, etc. The hand-force pump, which was introduced at the Chester show, has had a good reception at the hands of the owners of portable and traction engines. The pump can easily be worked by a boy, and as it is double acting and fitted with an air-vessel, it supplies a continuous jet of water which will swill out the water spaces in the boiler. It can be used for a variety of other purposes.

Messrs. Crossley Bros., Limited, of Openshaw, exhibit a variety of their well-known gas and oil engines. The first to attract attention is an "Otto" horizontal improved type of gas-engine of 25 h.p. nominal, capable of indicating about 65 h.p. at a speed of 160 revolutions per minute. It is fitted with two flywheels 7ft. 1in. in diameter by 10½in. wide, and a pulley 60in. diameter by 23in. wide. The engine is of the latest type, with patent permanent tube, the company's timing valve, safety starting gear for preventing running back at starting, quiet air suction, sensitive high-speed governor, and patent starter. There are two horizontal gas-engines of 9 h.p. nominal and 3 h.p. nominal respectively. Another engine at this stand is an "Otto" horizontal high-speed gas-engine for electric lighting. It gives 2½ h.p. on the brake, and runs at 300 revolutions per minute. This engine is fitted with two flywheels, each 3ft. 6in. diameter by 2⅞in. wide, and is specially adapted for driving dynamos. One of the gas-engines is shown actuating an Elwell-Parker dynamo, which supplies current to a number of lamps installed by Messrs. Baily, Grundy, and Barrett, of Cambridge. Among the company's improved type of petroleum oil-engines may be cited one of 2 h.p. nominal, 4½ h.p. indicated, and 3½ h.p. actual. The speed is 200 revolutions per minute; the flywheel is 4ft. 6in. diameter by 4½in. wide. The consumption of oil is stated to be one pint per brake horse-power per hour at full load. A second oil-engine of 10 h.p. nominal and 17½ h.p. indicated, and a third oil-engine of 4 h.p. nominal and 8¼ h.p. indicated, are also on view. An oil-engine of 6 h.p. nominal and 13 h.p. indicated consumes three-quarters of a pint of oil per brake horse-power per hour at full load. A portable engine entered for competition is also to be found at this stand. It is made suitable for a continuous working load of 11 h.p. effective. It is mainly of the same construction as the stationary oil-engine made by Messrs. Crossley Bros., and works on the "Otto" cycle. The total weight of the engine in travelling order is 3¼ tons. The engine is carried on three wheels—a pair of large wheels, on which the bulk of the weight rests, and a small swivelling leading wheel, to which the horse-shafts are attached.

Messrs. Samuelson and Co., of Banbury, show Griffin oil-engines, for which they are sole licensed manufacturers in England. It is claimed for these engines that the starting is easy and prompt, the igniting point certain, and the ignition absolutely reliable. The consumption of oil, which may be common petroleum, is small, and in exact proportion to the work done after the necessary amount of oil has been allowed for overcoming the friction of the engine when running empty. The governors give perfect control, and the highest possible mechanical efficiency is obtained.

The Blackman Ventilating Company, Limited, London, display several of their well-known fans, one of which is driven by a "Trusty" oil-engine, and is fixed to a tubular air-warmer, such as are supplied to warm the large quantity of air moved by the Blackman fans, especially for drying purposes.

Messrs. Marshall, Sons, and Co., Limited, of Britannia Ironworks, Gainsborough, and Marshall's-buildings, 79, Farringdon-road, London, have on view a large assortment of their leading specialities. One of the most prominent is a 16-h.p. portable engine of the firm's patent type of flush-top boiler, with sliding carriages for the crankshaft, and the engine work carried on wrought-iron stays entirely independent of the boiler. This is a powerful engine, of ample strength for working at 90lb. steam pressure, and capable of giving off a large amount of power. The 7-h.p. portable engine shown is of the company's usual type, which is now so well known as scarcely to need description. It is provided with enlarged firebox for burning inferior fuel, and is made with wrought-iron crankshaft carriages, diagonal force pump, and all their latest improvements. Messrs. Marshall, Sons, and Co. have also various engines of their make driving the machinery on other makers' stands.

Messrs. Alfred Williams and Co. show, among other exhibits, the Halladay windmill, for driving deep-well pumps and dynamos. This type of windmill is claimed to be the only automatically self-regulating windmill. The wheel consists of a skeleton framework, into which a series of wooden sections are centred, which vary in number according to the size of the windmill. The sections are connected with counterbalance weights, which balance them to such a nicety that when the wind presses too heavily on them, as for instance, in a storm, the wheel opens and assumes a tubular form, allowing the wind to pass freely through it, which stops the windmill. As the pressure decreases the sails tilt back again into their old position, when the windmill recommences work. The vane at the back acts as a rudder and keeps the wheel always facing the wind. We understand that the windmill which was removed from Messrs. Carwardine's, on the City-road, has recently been re-erected at Okehampton, where it is driving a dynamo and a mortar mill.

Messrs. Ruston, Proctor, and Co., Limited, of Lincoln, exhibit an 8-h.p. new type portable engine. The crankshaft brackets, the cylinder, stop, and safety valves, and the bracket for carrying the guide and governor stands are bolted to planed seatings or supports riveted to the boiler, so that not a single bolt for holding any of these important parts passes into the steam space. These seatings are faced up by putting the boiler bodily into the planing machine, and as the parts which fit to them are also planed, an absolutely mechanical job is secured. It is thus evident that at any time the engine can be removed from the boiler and be mounted upon an independent bed-plate. In addition, immunity is obtained from leakage of steam joints. The cylinder is steam-jacketed, and the governor is sensitive, of the high-speed type, and acts on an equilibrium throttle-valve. The feed pump works continuously, and is perfect in action, water not required by the boiler being returned through a regulating cock to the feed tank. The boiler has a large firegrate with heating surface in proportion, is of sufficient size to develop three times the nominal power of the engine, and is well stayed for a working pressure of 90lb. The firebox is extra strongly stayed and fitted with fusible safety plug to prevent accident in case of shortness of water. The grate has been increased in length so as to be suitable for poor coal or wood.

Messrs. Robey and Co., Limited, Lincoln, show a horizontal steam-engine fitted with their patent automatic trip expansion gear. This engine is of substantial construction, suitable for doing heavy work, and is at the same time provided with a high-class expansion gear for securing the greatest economy in fuel and perfect governing under varying loads. It can be employed for driving a dynamo for electrical illumination. A compound Robey engine and locomotive boiler combined is fitted with patent automatic governor and link expansion gear, and is suitable for driving dynamos, mills, factories, and other machinery

Digitized by Google

where steady running is required. In addition to the above, Messrs. Robey and Co., Limited, exhibit specimens of their medium and long stroke horizontal fixed engines fitted with their patent automatic governor and link expansion gear. The high-speed vertical engine exhibited is specially suitable for driving dynamos and other high-speed machinery, either by belt or by being coupled direct. The Robey horizontal fixed oil-engine (Richardson and Norris's patents) which is exhibited, is of the stationary type of eight effective horse-power. The cycle of operation is the now universal four-cycle, or Beau de Rochas—*i.e.*, an impulse is obtained every other revolution of the crankshaft when working up to maximum power. The engine proper closely resembles the Robey gas-engine, the only difference being in the combustion-chamber. There is also shown a Robey portable oil-engine of 10 effective horse-power. The design of the engine approximates closely to that of the portable steam-engine, and thus takes advantage of the years of experience which have proved that this is the easiest and most effective way of securing power in a portable form.

Messrs. Ransomes, Sims, and Jefferies, Limited, of the Orwell Works, Ipswich, have a large stand in the Machinery-in-Motion Department. The 6-h.p. and 8-h.p. portable engines on view have large steam-jacketed cylinders, wrought-iron crankshaft brackets, raised top fireboxes, and piston-valve governors. The 6-h.p. short-stroke engine is on a cast-iron foundation; the bed-plate, cross-head guides, and plummer blocks for crankshaft are all cast in one piece; the cylinder and valve chest are bolted to the end of the foundation frame. A four-horse vertical engine is connected with a new patent multitubular vertical boiler, which is so arranged as to present a maximum amount of heating surface in the smallest possible space, and ready access can be had to every part of the boiler for cleaning, etc.

Messrs. J. E. H. Andrew and Co., Limited, of Reddish, near Stockport, display two "Stockport" gas-engines. The first is an engine capable of developing 30 b.h.p. It is fitted with the company's self-starter, timing valve, ignition tubes, and an arrangement of governing by which the speed of the engine can be altered without stopping. This being very sensitive, it regulates the speed of the engine and controls the quantity of gas consumed in proportion to the amount of work done. The second engine develops 2 b.h.p. or actual horse-power, and is fitted with a sensitive vibrating governor and patent tubes. This engine is claimed to be one of the most economical engines of its size.

Messrs. Clarke, Chapman, and Co., Limited, of Gateshead-on-Tyne, display an improved type of fixed gas-engine of 35 b.h.p., constructed according to Butler's patents. This engine is specially suitable for driving dynamos for country mansions with Dowson's or other producer gas, the system of governing adopted rendering the running of the engine remarkably regular and uniform. Instead of using intermittently moving mechanism, such as cam-lift spring return poppet valves, levers, pumps, etc., the company have substituted one balanced, cylindrical, slowly rotating valve which performs the various functions. This valve is easily accessible, and can be removed for examination and replaced in a few minutes. The power and speed of the engine is capable of considerable variation. This is effected by a balanced regulator valve which admits an amount of explosive mixture to the cylinder, proportionate to the power and speed demanded, by means of which an impulse is obtained in every cycle and the engine given a very regular turning action. The engine is started by a small hand-pump by which the explosive mixture of gas or oil is supplied to a chamber, an electric exploder being used in connection with this and the cylinder. Two other engines, one portable and one fixed, are also on view.

Messrs. Clayton and Shuttleworth, of Lincoln, and 78, Lombard-street, E.C., are represented by a variety of their well-known manufactures. Among these is an 8-h.p. portable steam-engine. This engine is fitted with a jacketed cylinder and water-heater, and has an enlarged firebox of Low Moor iron or steel for burning wood or coal. The engine is constructed on a most approved principle for efficiency, economy of fuel, simplicity in its working parts, and durability. It is provided either with wood or wrought-iron travelling wheels. A second engine exhibited comprises a fixed long-stroke engine of 10 h.p. It is fitted with feed pump, patent governor, and automatic expansion gear; and is specially adapted for electric lighting purposes.

Messrs. Weyman and Hitchcock, Limited, of Guildford, display the "Trusty" oil-engine, which was also entered for the competition. The first to attract attention is the new pattern portable engine, capable of developing over 7 b.h.p., and fitted with patent water-cooling apparatus overhead. One of the principal points about this engine is that a few buckets of water are quite sufficient for a day's run. The oil-tank, which is placed very conveniently in the frame so as to feed oil-pump, is of a capacity capable of holding a supply of oil for two or three days' work. The engine is mounted on strong wrought-iron road wheels, with forged axles, and fitted with pole or shafts for draught. The whole arrangement is of compact design, and is specially handy for transport. A second oil-engine, horizontal, comprises one of 1½ b.h.p., or actual horse-power, and 2 i.h.p. This, like the portable engine mentioned, is a new departure, it being combined with a plunger pump, and capable of pumping 800 gallons of water per hour to a height of 100ft. Other exhibits at this stand are a single-cylinder horizontal oil-engine, working up to 6 b.h.p. and 9 i.h.p., and a single-cylinder horizontal engine, to work up to 7½ b.h.p., and suitable for using any of the ordinary oils. Some of these engines have been adopted for electric lighting, and one is shown driving a Statter dynamo supplying current to lamps on this stand, sawing, etc. A "Trusty" gas-engine has been installed on board the training ship "Conway," Rock Ferry, the engine being a double-cylinder one to give out 10 b.h.p., and running a dynamo feeding 120 lights.

Mr. C. Cadle, of 39, Wellington-quay, Dublin, exhibits a turbine manufactured by Messrs. Ridgway and Son, of Coatesville, U.S.A., capable of giving 5 h.p. He also has on view an improved impact waterwheel, adapted for driving mining machinery, dynamos, etc. Under a head of water 100ft., it will give 6 h.p., using 46 cubic feet per minute. The aermotor or windmill shown is made of steel, for pumping and other purposes.

Messrs. Pritchetts and Gold, of 31, Soho-square, W., demonstrate a complete electric lighting plant suitable for a country residence. It consists of a 9½-b.h.p. Hornsby-Akroyd oil-engine, a 200-light dynamo, set of 53 accumulators, switchboard with measuring instruments and regulator, and belting and connecting cables. This plant is capable of running 200 lamps of 8 c.p. or 100 of 16 c.p. continuously from the dynamo, or the full number from accumulators alone for 6½ hours, and half the number for 15 hours. Another exhibit comprises an electric pump of ½ h.p., manufactured by the C. & C. Motor Company, of New York, U.S.A. It is capable of raising 370 gallons per hour, can be worked off any incandescent electric lighting plant, and can be fixed at a considerable distance at small outlay. The Hunnings-Cone telephone, manufactured by the General Electric Company, of Manchester, is also shown on this stand.

MAGNETIC FRICTION AND HYSTERESIS.

Friction is a universal phenomenon of nature. Wherever motion, molar and molecular, takes place, energy is consumed by friction and dissipated as heat. Thus writes Mr. C. Proteus Steinmetz in the *Electrical World*. Continuing, he says: Thus, when iron is alternately magnetised and demagnetised, in the cycling motions of the molecules, which represent the change of magnetism, energy is consumed. This energy of magnetic molecular friction is converted into heat; the iron gets hot.

Since in almost all electro-dynamic machinery periodic changes of magnetism in the iron take place, it is obvious that the consumption of energy by this change of magnetism—*i.e.*, the molecular magnetic friction—is of the utmost importance as one of the fundamental factors determining the efficiency and the output of the apparatus. Thus, the predetermination of the molecular magnetic friction

Digitized by Google

becomes necessary. If a piece of iron is magnetised and demagnetised alternately, it has been found that during the rise of M.M.F. the magnetism is lower than during the decrease of M.M.F., so that during the rise of M.M.F. the same value of magnetism is reached at a higher M.M.F. than during the decrease. This phenomenon is called hysteresis—*i.e*, magnetic lag. Thus, if a piece of iron is exposed to alternating M.M.F., the magnetism, as function of the M.M.F., describes a closed curve, the loop of hysteresis. The change of magnetism induces in the magnetising circuit E.M.F.'s, which consume energy, and it has been proven that the energy consumed by these E.M.F.'s is proportional to the area of the hysteretic loop. This loss of energy in the magnetising circuit during the alternation of magnetism is called the loss of energy by hysteresis. As seen, the loss of energy by hysteresis has directly no relation to the loss of energy by molecular magnetic friction. But the energy consumed by magnetic friction must be furnished somewhere, and if no external source of energy is applied, the hysteresis furnishes the energy of molecular friction. But even then the hysteretic loop need not be equal to the energy of the magnetic friction, but hysteresis may, besides molecular friction, furnish mechanical energy also. Some cases may illustrate this.

In the alternating-current transformer, energy is neither supplied to, nor expended by, the iron, except in the magnetising circuit. Thus, in this case, the hysteretic loop equals the energy of magnetic friction—*i.e.*, hysteretic energy and molecular magnetic friction are identical. If however, the iron pieces of the transformer are loose, so that they are set in vibration by the alternating field, the mechanical energy of vibration has to be furnished by hysteresis, and the hysteretic loop increases, representing now the sum of the energy consumed by molecular magnetic friction and by mechanical vibration. On the other hand, if the iron of the transformer is set in violent vibration by an external mechanical force, a part of the energy of magnetic friction is supplied by mechanical power and not by the M.M.F., and thus the hysteretic loop collapses more or less, representing now only that part of the magnetic friction supplied by the M.M.F. In this case the loop may even become negative—that is, energy may be put into the electric circuit by the magnetic circuit as an electric generator.

The conclusion from all this is that hysteresis can be used for measuring the energy consumed by molecular magnetic friction only, when care is taken to exclude any external source or expenditure of energy. But if external transformation of energy takes place, as in revolving machinery, no conclusion can be drawn from the hysteresis with regard to the magnetic friction, and especially disappearance of hysteresis does not mean disappearance of molecular magnetic friction, but means that the energy of magnetic friction is supplied from another source.

THE HISTORY OF WOODHOUSE AND RAWSON UNITED, LIMITED,

As Detailed in the Bankruptcy Court.

WEDNESDAY.

The public examination of the directors and officers of this Company, a report of which was given in our last issue, was resumed on Wednesday, before Mr. Registrar Hood, at Bankruptcy-buildings, Carey-street, Lincoln's-inn.

Mr. C. J. Stewart again attended as senior official receiver; Mr. Muir Mackenzie, Mr. Butcher, M.P., Mr. H. T. Eve, Mr. C. E. Jenkins, Mr. J. A. Cartmell, Mr. Mossop, Mr. H. G. Rawson, Mr. Kebbell, Mr. Pilling, and Mr. Stirling appeared for directors and others interested in the proceedings; and Mr. W. M'Kay (Ward, Perks, and Co.) for debenture-holders and also for the Official Receiver.

Before the examination was commenced, **Mr. H. G. Rawson**, on behalf of the directors, stated that the important documents, which on a former occasion were alleged to have been "spirited away," had been found in a place from which they had never been removed. He submitted that the insinuation ought not to have been made by the Official Receiver.

Mr. Registrar Hood said he was of opinion that the Official Receiver had conducted the examination throughout with the utmost fairness and impartiality.

Mr. F. W. Pixley, whose firm had audited the accounts of the Company, was again called, and, in reply to Mr. M'Kay, stated that he intended the special report annexed to his certificate of July, 1892, to be taken as part of the certificate, because he considered that the accounts were not altogether reliable.

By **Mr. Pilling**: He was not in any way concerned with the estimate of £75,000 as profit for the year 1889 as set out in the prospectus. He assumed that the balance-sheets were prepared under the direction of Mr. F. L. Rawson, and witness obtained much information from that gentleman with reference to the figures. The amounts were compared with the entries in the books. He was aware that in the original accounts the goodwill and patents of Woodhouse and Rawson, Limited, were represented by 100 founders' shares of £1 each, but there were also £20,000 in cash and £30,500 in fully-paid shares.

Mr. Pilling pointed out that the patent rights were returned in the accounts at £64,000 and the goodwill at £75,000.

The **Witness** stated that he had nothing to do with the preparation of those figures. He was not aware of the amount realised under the liquidation of the old company. With reference to the sum of £37,325 returned as a profit in respect of the International Okonite Company, Limited, witness said that the sum was included as profit upon the advice of counsel, which was taken at his suggestion. He certainly considered that the profits had been earned, but, as a matter of fact, the dividend was not necessarily paid out of them, as a dividend had been guaranteed in any case. There was no truth in the suggestion that he had withdrawn his report without having satisfied himself that his conditions had been complied with and the pledges fulfilled.

By the **Registrar**: He considered that when the goodwill was fixed by the directors upon the purchase it was impossible to run the figure up and down according to the fluctuations of the profit.

At the conclusion of his examination **Mr. Pixley** made a statement as to his connection with the Company. He said with reference to the original prospectus of Woodhouse and Rawson United, Limited, issued in July, 1889, it was not, he believed, even pretended that anyone incurred any legal or moral responsibility by simply allowing his name to be placed on a prospectus as auditor. He should, of course, satisfy himself as to the respectability of the directors and as to the purposes for which the company was promoted, but the publication of his name was merely an indication to intending subscribers that he would be the person who would eventually audit the accounts at the expiration of the first financial year. When an industrial business was converted into a public company it was usual to obtain a certificate of profits from a chartered accountant who would make a special investigation for that purpose. In this case he was asked to give such a certificate, and it was in evidence that he had declined to do this. Although reference was made to the profits shown by the audited accounts of Woodhouse and Rawson, Limited, none whatever was made to the fact of his being an auditor, and no intending applicant for shares had, he contended, any right to assume that such was the case. If anyone took the trouble to call for the accounts he would have ascertained that they were accompanied by a special report from the auditors. His clients, and his sole clients, were the shareholders of Woodhouse and Rawson, Limited. At the same time, however, he wished it to be distinctly understood that although he declined to accept any responsibility in regard to those who might subscribe to Woodhouse and Rawson United, Limited, he had no reason whatever to doubt that the amount of profit referred to on the prospectus was absolutely correct, and would be ultimately realised. He had never been consulted upon, nor had he seen any of, the subsequent prospectuses. With reference to the balance-sheets of 1890-91-92, witness submitted that he had done his duty in passing the accounts for those years. The balance-sheet of 1891, in respect of which he had proposed to present a report to the shareholders, but which was withdrawn, was not in the same condition after he had dealt with it that it was when laid before him. Many alterations were made in the accounts as the result of the threatened certificate. In that certificate he called attention to the fact that nothing had been written off patents or patent rights and charged against profit and loss. The accounts ultimately signed included a sum of £4,156 written off for depreciation of patents. An undertaking was also given that the amount due from Mr. F. L. Rawson should be paid off, and the debt was subsequently extinguished. Other pledges and assurances were also fulfilled. He wished to endeavour to clear up a misapprehension which seemed to exist as to what a company's balance-sheet really was. It was a mistake to call the credit side of the balance-sheet the assets side, as by the process of book-keeping, all expenditure, including the amount paid for goodwill, would go to the credit side of the balance-sheet. With reference to the balance-sheet of July, 1892, witness said he found the books in the greatest state of confusion, a very large number of vouchers for payments being missing. He also ascertained that the anticipations of the directors as to the sale of the shares were not being realised, and that money was being borrowed at high rates of interest. He, therefore, came to the conclusion that he could not to sign those accounts, and affixed a special certificate to them stating that it was necessary to make a special report to the shareholders, calling their attention to the general unsatisfactory position of the affairs of the Company. It had been suggested to him in the course of the examination that it would have been better had he issued such a report with the accounts of July 31, 1891. He admitted that in the light of present knowledge it might have been better if he had done so, but an auditor ought not to act upon impulse, and he considered that he was right in signing the accounts in 1890 and 1891. Witness added that the Board of the Company was composed of men of high reputation. They had been entrusted with the management of the affairs of the Company, and he had every reason to believe they were acting solely in the interests of the shareholders. Should an auditor suspect that the

Digitized by Google

directors of a company were misapplying its funds or carrying on the business to their own interest at the expense of the shareholders, he might consider—and he was glad to say that the members of the Institute of Chartered Accountants did so consider—that an auditor should step outside what might be considered his bare duty and interfere, but in this case he had no such suspicion. He therefore submitted that he had done his full duty towards the shareholders of the Company, and that whatever blame might, as the result of this enquiry, be attributed to the officials, none whatever could be laid upon the auditors.

Sir John Stokes, K.C.B., was next examined by the Official Receiver. He stated that he had acted as a director of Woodhouse and Rawson, Limited, from the time of its formation, and subsequently was appointed liquidator of that Company, in which he was a large shareholder, and to that extent he was interested in the sale to the new company. He also became a director of the new company. So far as he was aware, the latter received all the patents and patent rights which were not reserved in the agreement. He did not consider that his positions at all clashed, and, as a matter of fact, he did not join the Board of the new company until after the allotment. He did not make any enquiries into the various agreements for the purchase of the buisnesses, nor into their position, but left the matter to the other directors, all of whom were competent men. When Sir John Coode, Colonel Howard Vincent, and Sir A. J. Cappel retired he took no steps to enquire into the position of affairs. He was not aware that the Woodhouse and Rawson Electric Manufacturing Company, according to the audited balance-sheet of June 30, 1889, began the year with a loss of £34,936 and ended the year with an accumulated loss of £44,718. The assets transferred to the United Company consisted partly of an option to call for certain Elmore shares, and of the profit returned in the balance-sheet of June, 1890, a sum of £29,437 was entered as profit in respect of those shares. Some doubt arose as to whether the shares had been transferred to the Company or not, but the liquidators of the old company gave way, and the United Company retained them. He could not say that one thing which induced the liquidators to give way was the fact that they were promised the return of the £75,000 deposited as a dividend guarantee fund. As a liquidator, he was naturally anxious that the fund should be returned, and he considered that he was acting in the interests of both companies in urging the return, as the larger part of the profits was being absorbed by the holders of founders' shares, and he wished to make it available for all the shareholders. He understood from the first that the Company was to carry on a financial as well as an industrial business. Reference was made in the first prospectus to the fact that a considerable profit had been realised from the first-mentioned branch by the old company. He admitted that the prospectus would give any reader to understand that the Company was carrying on an industrial business. He could not say that ever since 1887 there had been a continued loss on the industrial trading. Losses had been made on shares—in one case to the extent of £55,000. He could not admit that the "deal" in Elmore shares was the only successful operation carried out by the old company. With reference to the United Company, profits had been made over the promotion of the Kensington Co-operative Stores (£17,000) and the option to take Elmore shares, which realised a sum of £20,000. The profit of £35,000 in respect of the Epstein Accumulator Company, Limited, consisted merely of securities of that company. A sum of £46,000 had been invested in the Okonite Company, Limited, and witness admitted that this sum might have been used to advantage in the industrial business. In January, 1890, a prospectus was issued in which it was stated that, owing to the successful working of the United Company since its formation, an interim dividend at the rate of 15 per cent. on the ordinary shares and 8 per cent. on the preference shares had just been paid. He could not remember what accounts were before the Board when they declared that dividend, and after the lapse of five years he could not be expected to remember the reasons which induced him to consider that the profits had been earned. He denied that there was any special motive for making the third issue of shares coincide with the payment of the interim dividend. He was not aware until January, 1892, that Mr. Albert Grant was connected with the Phœnix Trust, of which Mr. F. L. Rawson was a director. He had nothing to do with the drawing of the prospectus, and did not see it until it had been issued, and he therefore could not accept any responsibility for the statements contained in it.

In reply to **Mr. F. L. Rawson**, witness said he attributed the failure of the Company largely to the depression in the financial business, owing to which the directors were unable to take up valuable patents. He had never known Mr. Rawson to act otherwise than straightforwardly.

Mr. M. J. R. Dundas, who acted as secretary of the Company, was also briefly examined by the Official Receiver. He stated that he was appointed upon the nomination of Mr. F. L. Rawson. He would not say that he was secretary in name only.

THURSDAY.

The examination by the Official Receiver of **Mr. Dundas** was resumed yesterday. The witness stated that he did not prepare a circular sent out relating to the retirement of three of the directors, but that it was sent out in the ordinary way of business.

Lord Aberdare, who was one of the original directors of Woodhouse and Rawson United, stated that he had a considerable interest in Woodhouse and Rawson, Limited. He understood when he consented to become a director that the idea of the new company was that it should be wholly industrial. He was present at the Board when the draft prospectus was finally settled, but just after he fell ill and was away from business for many weeks. In fact, he was away from the middle of July to the end of October and was not able to attend a meeting until December. He did not attend regularly until February. He found, however, that the duties were such as he could not well fulfil, and he ultimately resigned at the October meeting of shareholders. Referring to the report of the auditor for the year 1888, he remarked that it did not come before him at the time, but subsequently it became the subject of correspondence. Upon the question of stated profits, the directors examined everything very carefully and must have been satisfied before accepting the amount. They must also have investigated the amount for goodwill and for patents, and after careful examination they must have been satisfied. The fee stated as to be paid for valuation was, he thought, inadequate, but he was unaware of what the arrangement was. He had no special communication with retiring directors, nor of the minute nor circular; in fact, he did not agree with the terms of the minute. No doubt the question of interim dividend was communicated to him. He was astonished to learn about the auditor's report which was attached to Woodhouse and Rawson balance-sheet of 1888. A large amount of correspondence passed between him and other members of the Board relating to various questions upon which he required information. He stated that he always got the information he asked for as far as it was possible to be given.

Mr. A. Hoster was one of the liquidators of Woodhouse and Rawson, Limited, but a large part of his holding belonged to Mr. F. L. Rawson. He said that he did not recollect exactly why Mr. Rawson's shares stood in his name. He knew Mr. Rawson as a partner in Woodhouse and Rawson, and was consulted at the formation of the limited company, of which he became a director. He could not recollect Mr. Pixley's report to the 1888-9 accounts. He agreed that the amount due by the manufacturing company was £37,000, but could not state what was received for this debt. He had not realised anything from the shares of the manufacturing company. The supply company was also in debt to the amount of £11,000, and as liquidator he held 12,000 shares, but he recollected no specific amount received for these shares. He held £22,000 shares in the Universal Automatic Machines Company, for which he received 1s. each under the advice of the solicitors to finish the liquidation. They also owed a debt of £13,000, but it was valueless. He was a director appointed by Woodhouse and Rawson United, and on the Barcelona Company he acted as vice-chairman. He heard observations of a claim against Woodhouse and Rawson United. The debts of manufacturing company were collected and handed over to the United Company. He held that the debt of the manufacturing company at the time it was taken over was certainly good. He had expected to make a profit of from £60,000 to £70,000 on the Barcelona work. With regard to the Automatic Company there were arbitration proceedings which took between two and three years, and the arbitration was in favour of Woodhouse and Rawson United. The Automatic Company took up the award and went into liquidation; hence the claim for debt on account of shares was of no value.

ELECTRIC LIGHTING PROVISIONAL ORDERS.

The proposals contained in the provisional orders included in the Electric Lighting Provisional Orders (Nos. 3 and 5) Bills have been embodied in two official papers published on Wednesday. The following are extracts from the Bills:

Crystal Palace District Electric Lighting Order, 1894.—The undertakers under this order are the Crystal Palace District Electric Supply Company, Limited. The area of supply is portions of the district of the Beckenham Local Board, the borough of Croydon, the parish of Lambeth, the district of the Lewisham District Board of Works, and the parish of Camberwell. The order is to be read in conjunction with the Crystal Palace and District Electric Lighting Order, 1890, and varies the area of supply authorised by that order. The order also provides for the revocation of the Crystal Palace District Electric Lighting License, 1893.

Oswestry Electric Lighting Order, 1894.—The undertakers are the Oswestry Electric Light and Power Company, Limited. The area of supply is the borough of Oswestry. The order contains a provision that the undertakers shall lay down mains in certain specified streets within a period of two years, and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions; and also a provision for the purchase of the undertaking by the local authority after the expiration of 35 years from the commencement of the order on certain terms specified in the order.

Plymouth (Corporation) Electric Lighting Order, 1894.—The undertakers are the Corporation of Plymouth. The area of supply is the borough of Plymouth. The order contains provisions that the Corporation shall lay down mains in certain specified streets within a period of two years, and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions. The order also contains provisions for the approval by the Board of Trade of the system upon which energy is to be supplied, and the issue by them of regulations for securing the safety of the public and for ensuring a proper and sufficient supply of energy, and for the transfer to any company or person of the powers, duties, and liabilities of the Corporation under the order by means of a deed to be approved by the Board of Trade, upon such terms and subject to such exceptions and modifications (if any), and for such period, as may be specified therein.

Digitized by Google

Shropshire Electric Light and Power Company Electric Lighting (Shrewsbury) Order, 1894.—The undertakers are the Shropshire Electric Light and Power Company, Limited. The area of supply is a portion of the borough of Shrewsbury. The order contains provisions similar to those referred to in the case of the Oswestry Electric Lighting Order, 1894. The order also contains provisions for the purchase of the undertaking by the local authority after the expiration of 21 years from the commencement of the order, or any subsequent period of seven years, on certain terms specified in the order.

Wakefield (Corporation) Electric Lighting Order, 1894.—The undertakers are the Corporation of Wakefield. The area of supply is the city of Wakefield. The order contains provisions similar to those referred to in the case of the Plymouth Corporation Electric Lighting Order, 1894.

Clonmel Corporation Electric Lighting Order, 1894.—The undertakers under this order are the Corporation of Clonmel. The area of supply is the borough of Clonmel, and portions of the district of the Board of Guardians of the Clonmel Union. The order contains provisions that the Corporation shall lay down mains in certain specified streets within a period of two years, and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions. The order also contains provisions for the transfer to any company or person of the powers, duties, and liabilities of the Corporation under the order by means of a deed to be approved by the Board of Trade, upon such terms and subject to such exceptions and modifications (if any), and for such period as may be specified therein.

Collier-Marr Moss Side Electric Lighting Order, 1894.—The undertakers are the Collier-Marr Telephone and Electrical Manufacturing Company, Limited. The area of supply is the urban sanitary district of Moss Side. The order contain provisions: (1) that the undertakers shall lay down mains in certain specified streets within periods of six months and two years respectively; and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions; and the order also provides for the transfer of the undertaking to the local authority by agreement, with the consent of the Board of Trade, and for the purchase of the undertaking by the local authority at any time before the expiration of 25, 35, or 42 years, on specified terms.

Yeadon Electric Lighting Order, 1894.—The undertakers are the Yeadon Local Board. The area of supply is the urban sanitary district of Yeadon. The order contains provisions similar to those referred to in the case of the Plymouth Corporation Electric Lighting Order, 1894.

COMPANIES' MEETINGS.

ELECTRIC AND GENERAL INVESTMENT COMPANY, LIMITED.

The fifth ordinary general meeting of this Company was held on Tuesday at Winchester House, Mr. George Herring presiding.

The **Chairman** said the profit and loss account showed a gross profit on the transactions of the year of £10,735, and after deducting all standing charges and the interim dividend already paid, there remained £7,369 available for distribution. The directors had made a provision of £8,000 for contingencies. The contingent liability amounted to about £35,000, but the directors were satisfied that the capital represented in the enterprises in which they had shares was well worth the money they had paid or might have to pay. The investments were taken at cost, and even in these depressed times the amount at which they stood could be easily realised.

The report was adopted, and a dividend of 40 per cent. for the half-year, making 25 per cent. for the year, was declared on the ordinary shares, and of £30 on each of the founders' shares.

REUTER'S TELEGRAM COMPANY, LIMITED.

The ordinary general meeting of Reuter's Telegram Company, Limited, was held on Wednesday at the Company's offices, Old Jewry.

Admiral Sir J. C. D. Hay, who presided, expressed regret that the subscriptions to their various news services in India, the Straits, and China, and elsewhere, being paid in silver, they had lost considerably by the decline in the value of the rupee and dollar respectively. The loss due to this cause would be apparent when he reminded them that the difference between 1s. 6d. a rupee, the rate current when their contracts were entered into, and the actual rate meant a loss to them in India and the Straits alone of about £2,000 per annum. The partial paralysis of trade arising from the same cause had reacted on their business in other departments. They did not fail at once to make the necessary changes, and hoped that the fresh arrangements would improve their position before the end of this year. Large outlays were rendered necessary by the protracted civil war in Brazil, the troubles in Argentina, and the Matabele campaign, not only in telegrams, but also in obtaining the information embodied in them. The accuracy and promptitude of their service regarding these matters had been generally recognised, and he was happy to be able to inform them that they now enjoyed a larger measure of support from the Press than they had done at any previous period of their history. They were put to a great deal of unexpected expense last year owing to the action of a news organisation in the United States with whom they had a contract for some time. They had been saddled with heavy outlays, which considerably swelled the amount figuring in the accounts under the head of expenses. This matter was now before the Courts, and they hoped to obtain compensation for the loss they had sustained. After stating that their present arrangements in America were most satisfactory, he moved the adoption of the report, which was seconded by the **Hon. Mark F. Napier, M.P.**, and carried.

HOBART ELECTRIC TRAMWAY COMPANY, LIMITED.

The first annual general meeting of the Hobart Electric Tramway Company, Limited, was held on Wednesday at the offices, College-hill-chambers, Cannon-street, E.C., Mr. G. D. Mackay presiding.

The **Chairman** said: The Company was registered on March 4, 1892, and our report is for the period to December 31, 1893. You will recollect that under the contract with the original company it was provided that the vendor company should complete the lines to the satisfaction of this Company, and hand over the same in time to enable Messrs. Siemens to commence the running by January 1, 1893, and by the contract with Messrs. Siemens it was provided that the lines should be open for public traffic by that date. Instead of opening the line on January 1, 1893, we were unable to do so. After the plant had arrived in Tasmania, a difficulty arose with the Government at the instance of the local telephone company, which alleged that our service would interfere with theirs. This difficulty proved to be serious, and involved protracted delay, but eventually it was amicably adjusted under an agreement by which our overhead wires were placed so as not to interfere with those of the telephone company. The service was opened on September 21 last, and the tabulated statement in the report shows with what result, there being a surplus after providing for the charges of maintenance. Under Messrs. Siemens's contract they undertook to work the line for 12 months from December 31, 1892, at 4d. per car mile, receiving not less than £1,000 per month, including in same wages of conductors, drivers, and of all the necessary maintenance staff. By a subsequent arrangement with Messrs. Siemens they undertook to work the line to March 31 last, on which date we took the maintenance into our own hands, having, with Messrs. Siemens's concurrence, entered into an agreement with their Mr. Parker to supervise the running. Under this arrangement we know that there will be a considerable annual saving. We consider ourselves fortunate in having secured the services of Mr. Parker, who acted as Messrs. Siemens's engineer during the period of construction. Referring to the balance-sheet, you will observe that no revenue account has been submitted. We propose that all payments and receipts to December 31 last be put to capital account, and that the revenue account shall commence as at January 1, when it might be held the Company had really a start. In next year's statement a profit and loss account will be submitted. I now move the adoption of the report and balance-sheet.

Mr. A. Mattei, LL.D., seconded the motion, which was carried.

BUSINESS NOTES.

Bristol.—The Electrical Committee of the Town Council held a short meeting on Friday last.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,401.

Romsey.—Complaints have been made in the Town Council regarding gas lighting of the streets.

Central Chili Copper Company, Limited.—This Company has been registered with a capital of £255,000

City.—A new block is being added to the City of London School. It is to be lighted by electricity.

Liverpool Rubber Company, Limited.—This Company has been registered with a capital of £123,117. 10s.

Pupil.—Mr. W. Claypole will shortly have a vacancy at the Phœnix Electrical Works, Derby, for an articled pupil.

Removal.—Messrs. Bolton, Fane, and Co. have removed to West India House, 98, Leadenhall-street, London, E.C.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 24th inst. amounted to £820.

Llandudno Electric Supply Company, Limited.—The capital of this Company, to which we referred last week, is £15,000 in £10 shares.

Appointment Open.—As will be seen from our advertisement columns, a firm of engineers want an electrical engineer to design dynamos and motors.

Electrical and General Investment Company, Limited.—The warrants for the dividends on the ordinary and founders' shares have been duly posted.

Messrs. J. Crossley and Sons.—The directors of John Crossley and Sons, Limited, have declared an interim dividend of 2s. 6d. on the ordinary shares.

Sale of Patent Rights.—Messrs. H. F. Joel and Co. offer for sale the patent rights of their alternating motor for France, Belgium, and the States.

Hemming and Co., Limited.—This Company is being formed to acquire the business of Messrs. T. L. Hemming and Co., Limited, of Snow-hill, Birmingham.

Digitized by Google

Leeds Tramways.—The Leeds Corporation Tramways Committee arrived in Edinburgh on Tuesday, for the purpose of obtaining information as to the cable tramways.

Ship-Lighting.—The Union Steamship Company's new steel twin-screw steamer "Guelph," which has been built at Messrs. Harland and Wolff's yard at Belfast, is to be fitted with the electric light.

India Rubber and Gutta Percha Company.—The directors of the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, recommend an interim dividend of 5 per cent., or 10s. per share, tax free.

Edison and Swan Company.—The Edison and Swan United Electric Light Company, Limited, will on August 27 next remove into their new premises, Ediswan-buildings, 36 and 37, Queen-street, Cannon-street, E.C.

Catalogue Received.—Messrs. Howard B. Little and Co., 20, Eldon-road, Kensington, W., send us a list of specialities manufactured solely by them. These comprise ringing bells, invalid or portable bell sets, medical coils, and sundries.

Oriental Telephone and Electric Company, Limited.—Notice is given that the first ordinary general meeting of this Company will be held on Wednesday, July 4, 1894, at 1 o'clock p.m., at Winchester House, Old Broad-street, London, E.C.

Cork.—The subscription list of the Cork Tramways Company, Limited, was opened on Saturday last, and will close to-morrow. The capital is £25,000. The tramways authorised will have a total length of 3½ miles, and there is power to adopt either electric or horse traction.

Ronald A. Scott, Limited.—This Company has been registered by H. W. Reeves and Son, Temple, with a capital of £10,000 in £1 shares, to acquire the business carried on by Mr. R. A. Scott at Acton Hill, W., and to carry on business as electrical engineers and electricians.

Eastern Extension, Australasia, and China Telegraph Company.—The directors of the Eastern Extension, Australasia, and China Telegraph Company, Limited, have declared an interim dividend for the quarter ending March 31 of 2s. 6d. per share, free of income tax.

Lancashire Boilers Required.—As mentioned in our last issue, the London County Council invite tenders for two new Lancashire boilers and fittings at the Council's Central Works, Belvedere-road, Lambeth, S.E. No tenders will be received after 10 a.m. on Monday, July 2.

Patents Pioneer Syndicate, Limited.—This Company has been registered with a capital of £10,000 to carry on business as bankers, capitalists, etc., especially in relation to dealing with inventions and letters patent; also as mechanical, civil, and electrical engineers, etc.

Aberdare.—The Examiners of the House of Commons have certified for second reading a provisional order made by the Board of Trade, enabling Messrs. J. C. Howell, Limited, to supply electrical power at Aberdare. The order has already passed through the House of Lords.

Electrical Engineer Required.—The Vestry of St. John, Hampstead, want an electrical engineer to take charge of their station, at a salary of £200. He must have practical experience of alternating-current central-station work. Application is to be made not later than by Monday next.

Wakefield.—The Wakefield electric lighting order, empowering the Wakefield Corporation to manufacture and supply electricity within the city of Wakefield, has come before the Examiner of Private Bills at the House of Commons, who certified that the Standing Orders had been complied with.

The Nova Scotia Cable.—Reuter's Agency states that information received by the Commercial Cable Company from the "Faraday" on Tuesday, gave the position at lat. N. 49 45, long. W. 43 36. Cable had been paid out to the extent of 1,338 miles. All were well, and the insulation of the cable was perfect.

City and South London Railway.—The receipts of the Company for the week ended June 24 were £863, against £765 for the same period last year, or an increase of £98. The total receipts for the first half-year of 1894 show an increase of £817 compared with those for the corresponding period of 1893.

Windsor.—Messrs. Roger Dawson, Limited, are carrying out the electric lighting of Clewer Park, the residence of Sir H. D. Gooch. They are installing about 100 lamps, with steam-engine, dynamo, and accumulators. The work is being carried out under the superintendence of Mr. A. E. Farrow, their Windsor manager.

Salt Lake Electric Light Company.—The Gas, Water, and General Investment Trust, Limited, notify that the coupons of the Salt Lake and Ogden Gas and Electric Light Company's first mortgage 6 per cent. bonds due July 1 next will be paid at the National Provincial Bank of England, Limited, Bishopsgate-street, on and after July 2.

Tenders for Lambeth.—Tenders are invited by the Lambeth Guardians for (1) two Galloway boilers and engineer's work, and (2) new smoke shaft and builder's work, at their workhouse, Renfrew-road. Forms of tender may be obtained and the specifications, drawings, and drafts of contracts may be inspected at the offices, Brook-street, Kennington-road. Tenders are to be sent in by July 4.

Lighting of the Big Wheel.—Messrs. J. G. Statter and Co., Limited, have received the contract for the electric lighting of the gigantic wheel at the Earl's Court Exhibition. The order is for the generating plant, the lighting of the 40 cars on the wheel, and the illumination of the wheel itself with 160 lamps. The whole installation is for 280 lamps.

Northern Engineers' Supply Company, Limited.—This Company has been registered with a capital of £3,000 in £5 shares to carry on business as dealers in all articles and goods required by or usually supplied to ironfounders, mechanical engineers, railway companies, etc. The first directors are Sir W. H. Bailey, Kt., J. Frankenburg, A. Bailey, and James Tinto.

Mill-Lighting.—The Leeds Association of Engineers visited Burley-in-Wharfedale on Saturday and inspected the Greenholme Worsted Spinning Mills. The lighting is entirely by electricity, about 2,000 lamps being employed. The electric plant was designed by Mr. Wilson Hartnell, of Leeds, and the dynamos, etc., were supplied by Messrs. Crompton and Co.

Salisbury Electric Light and Supply Company, Limited.—This Company has been registered with a capital of £20,000 in £1 shares to produce and supply electric current for light or power in the city of Salisbury. The first directors—to be not less than three nor more than six—are to be elected at a general meeting. Qualification, £250. Remuneration, £50 each per annum.

Liverpool.—The Watch Committee have received a letter from the solicitors to the Liverpool Electric Supply Company, giving formal notice of the company's intention to apply for a provisional order to supply electricity for public and private purposes in various parts of the city, including Queen-street, Oldhall-street, Devonshire-road, Springfield-street, and the Goree Piazzas.

Telephony to the Fair Isle.—Telephonic materials are being despatched from Kirkwall by the steamer "Fawn" to the Fair Isle, which lies midway between Orkney and Shetland, to be used in connection with the scheme for instituting telegraphic communication between lighthouses and the coasts. A telephone line is to be constructed between the lighthouse and the south of the island.

Tenders for Wolverhampton.—As notified in our advertisement columns, the Lighting Committee of the Corporation of Wolverhampton invites tenders for the supply of electric fittings suitable for the Town Hall, Art Gallery, School of Art, Free Library, and Market Hall; and for the electric wiring and erection of selected fittings. The Corporation is open to receive applications for a working foreman engineer.

Reuter's Telegram Company, Limited.—The report of this Company for the year ended December 31 shows, after payment of charges and deducting rebate on unexpired subscriptions, a debit balance of £2,767. The expenditure occasioned by the war in Brazil, the troubles in Argentina, and the Matabele campaign, together with the losses sustained owing to the fall in the Eastern exchanges, are said to explain the unfavourable results of the year's working.

Dewsbury.—Mr. Wm. Newsome, pianoforte manufacturer, of Ravensthorpe, is erecting new buildings at the junction of Croft-street and Bond-street, to serve as shops and offices. He has decided to have them lighted by electricity. The installation will consist of a 100-light dynamo, four arc lamps, and 72 16-c.p. incandescent lamps, and a 6-h.p. gas-engine fixed on the premises. The order has been placed with Messrs. A. Hirst and Son, electrical engineers, Crescent Works, North-street.

New Firm.—Mr. G. E. Piggott, who has for some years acted as representative for Mr. R. Applegarth in his electrical supply business carried on at 11, Queen Victoria-street, E.C., has resigned his connection with that gentleman, and commenced operations in the wholesale and retail electrical supply trade at 110, Cannon-street, E.C., under the name of Piggott and Co. We cordially hope that the new firm will prosper as much as the undoubted industry and ability of its head would merit.

Plymouth.—At the House of Commons the Bill confirming a provisional order of the Board of Trade conferring powers on the Corporation of Plymouth for the electric lighting of the borough has been before Mr. Thoms, one of the examiners of private Bills, for the investigation of the necessary Standing Order proofs after its first reading in the Commons. Mr. Woodward, of the firm of Sir Richard Wyatt and Co., appeared for the Board of Trade, and submitted proofs and evidence which satisfied the examiner that the Standing Orders of Parliament had been complied with.

Tenders for West Ham.—Tenders are invited for the electric lighting at the Public Hall and free library, Barking-road, Canning Town, E., for the West Ham Town Council. Specification, form of tender, and further particulars, may be obtained at the office of Mr. Lewis Angell, borough engineer, Town Hall, Stratford, E. Tenders, endorsed "Tender for Electric Lighting," are to be sent to Mr. Fred. E. Hilleary, town clerk, Town Hall, West Ham, by 4 p.m. on July 10. The contractor will be required to enter into a bond with two sureties for the performance of the contract.

Cardiff.—A special meeting of the Lighting Committee of the Cardiff Corporation was held on Monday at the Town Hall to appoint four engine fitters at the new electrical engineering works. The 10 candidates who, as we stated last week, were selected at a previous meeting out of 120 applicants to appear before the committee attended. Their testimonials having been read and the applicants examined by the members of the committee as to their experience and ability, the following were appointed to fill the positions: Messrs. Arthur Knight, W. S. Melhuish, D. W. John, and F. A. Parker.

Barnet.—At a meeting of the Local Board, a letter was read from Messrs. Crompton, thanking the Board for a copy of its resolution of the 5th inst. (recorded in our issue of 15th inst.), and stating that they would be glad to know when it was convenient

Digitized by Google

for the committee to meet a representative of the firm. Mr. A. W. Fereday, hon. secretary of the Barnet Ratepayers' Association, wrote enclosing a copy of a resolution passed by the association on the 14th inst., with only one dissentient: "Seeing that the Local Board is negotiating for the introduction of the electric light, this meeting hopes that the Board will accept no scheme which will involve any charge on the rates for the purpose of a speculation in electric light." Both letters were referred to committee.

Leeds.—The Lamp Committee of the Leeds Corporation have had before them a letter from the Yorkshire House-to-House Electricity Company, requesting the committee to consider the desirability of illuminating some of the streets in the centre of the city with the electric light. In order that there might be a fair trial, the company offered to supply the electric current for any number of arc lamps up to, say, 30 on the line of mains at 4d. per unit net. The committee, however, felt that the proposal was somewhat untimely. It was pointed out that they had recently spent a large sum of money in fixing Bray's lamps in the principal streets, and would scarcely be justified in going to further expenditure at present. The letter was therefore ordered to lie on the table.

Bolton.—Since the work of constructing the transforming centres in connection with the Bolton electric lighting undertaking was commenced, public interest in this important work has been considerably developed, and enquiries are very frequent as to how soon the Gas Committee will be ready to supply the new illuminant. Since the decision of the Town Council to supply consumers with the requisite fixtures on an easy payment system, applications for a supply of electricity have considerably increased. The works at Spa-road are being rapidly pushed towards completion; the three boilers have been some time in position, and the boiler-house is now in process of being roofed in. Other portions of the building are in an equally forward state, and its chimney has reached the intended height, and now only awaits the ornamental coping stone to complete it.

Dundee.—Mr. Brownlee, the electric lighting engineer, has recommended that the works be extended by the introduction of a 200-h.p. engine with dynamo. At present the station has 660 h.p., and, with the addition, it will have a capacity of about 1,800 lights. This will be sufficient for the ensuing winter, but it is anticipated a further extension will be required in the succeeding year. The Works Committee of the Gas Commission have arranged to have two electric lamp-posts placed in front of the new offices in Commercial-street. The Gas Commissioners have resolved that the electric light be supplied at 5d. per unit. According to the convener of the Finance Committee of the Gas Commissioners, the deficit on the electrical department, amounting to £1,721, has been wiped off out of the gas revenue. There are now 186 electric light consumers, with 5,293 16-c.p. lamps.

Electric Lighting in St. Pancras.—The total income of the St. Pancras Vestry in respect to electric lighting has been £15,022 during the year. This sum is sufficient to clear off the deficit of the first year—£1,543—and after paying all the working expenses and £927 in maintaining the works, a balance of £4,669 is left, out of which interest and repayment of loans have to be met. The tender of Mr. J. O. Richardson, of Peckham, was accepted for the erection of the main buildings, boundary walls, etc., of the King's-road station at £5,178. The Electricity Committee reported that Messrs. Kelly Bros. were communicated with respecting the employment of London men in executing the work of building the main central-station buildings, but they stated that they could not put themselves under any restrictions as to the men employed, and withdrew their tender. The committee have therefore decided to invite fresh tenders.

Worcester.—The Mayor of Worcester (Mr. G. H. Williamson) moved, at a meeting of the Town Council, a recommendation of the Watch Committee that the price for the electric light should be fixed at 5d. per unit. This figure would yield a very handsome profit in reduction of the rates, if the power they were providing was taken advantage of by the citizens. He pointed out that they were utilising the water power of the Teme, which would be of great assistance in making the installation a profitable one. Electric pumping machinery was going to be fixed at the waterworks for raising water to the higher levels, which would, as compared with steam machinery, effect a saving of £600 a year. If they could only calculate on 600 h.p. being used for four hours a day for 300 days in the year, there would be, at 5d. per unit, a revenue of £7,500. The present investment in the works was £46,000. The motion was agreed to.

Bournemouth.—We reported in our "Notes" last week that Mr. F. H. Tulloch had held a Local Government Board enquiry into the proposal of the Town Council to borrow £4,000 for the purposes of the electric lighting of the pier and gardens. In connection with this and allied matters the Council have approved of the following items in the report of the Electric Light Committee: "The surveyor's report on the power at his disposal for electric lighting purposes was read, from which it appeared that a saving of £150 a year might be effected by the Council lighting the winter garden. The committee recommended that the report be laid before Mr. E. M. Lacey, electrical engineer, under the resolution of the Council. The committee recommended that the town clerk write the electric supply company asking if they would be prepared to make any (and what) reduction in the cost of lighting the winter garden under an agreement for a term of years."

Glasgow.—At a meeting of the various municipal trusts, the return asked for by Mr. W. F. Anderson as to the telephonic connections rented by the Corporation and the several trusts from the National Telephone Company, Limited, and the rentals paid therefor, was submitted. It showed that there were 31 connections in all, and the rentals paid by the various departments were: Corporation, £21; municipal buildings, £173. 10s.; improvements, £34. 10s.; markets, £25; parks, £15; Contagious Diseases (Animals) Acts, £40. 5s.; water, £9; and gas and electric lighting, £178. 15s.; a total of £497. The Glasgow Water Commissioners decided to enter into a five years' agreement with the National Telephone Company for a telephonic connection between their office in John-street and Strathblane, with loop lines to the other stations belonging to the Commissioners between these two places, and also to Maryhill, for a sum of £93 per annum.

Tenders for Edinburgh.—Tenders are invited for the following in connection with the electric lighting of the city, for the Corporation: contract No. 6A, supply of cast-iron road boxes; contract No. 10, supply of copper strip connectors, etc.; contract No. 11, supply of gunmetal grip-boxes; contract No. 12, supply of cable connectors and cones. Copies of any of the specifications and drawings can be obtained from the resident electrical engineer, City Chambers, Edinburgh. All information will be supplied by Prof. A. B. W. Kennedy, consulting electrical engineer to the Corporation, 14, Old Queen-street, Westminster, London, S.W., and by Mr. E. W. Monkhouse, resident electrical engineer, City Chambers, Edinburgh. Firms wishing to obtain copies of any of the specifications must send with their written application a deposit of 10s. 6d., which deposit will be returned on receipt of a *bonâ fide* tender. Tenders are to be directed to Mr. Wm. Skinner, W.S., town clerk, City Chambers, Edinburgh, and must be received in Edinburgh not later than July 4.

Lighting of Bradford.—The town clerk mentioned at a meeting of the Council on Wednesday that there was a matter to which it was necessary to call attention, the Electricity Committee stood in need of some new boilers, the cost of which was £2,875. The committee were anxious to have two boilers which were now ready, but it was necessary to have the sanction of the Council before the boilers could be received. In order to save time the Council were asked to deal with the subject at this special meeting. The boilers were supplied by Messrs. Thwaites Bros., Limited, of Bradford, and were described as two marine boilers, fitted with Ellis and Eaves's system of induced draught. Alderman Moulson, chairman of the Gas and Electricity Supply Committee, said the Council determined some months ago that tubular boilers should be obtained for the electricity works, and they had now been obtained. It was very necessary that the new boilers should be got in before winter came, and if the Council gave the necessary power that afternoon they could be laid by about October. He proposed that the action of the committee with respect to the purchase of the boilers should be confirmed. The motion was seconded, and after some discussion it was adopted.

Aberdeen.—At a meeting of the Education Committee of the Governors of Gordon's College, tenders for the fitting up of appliances for lighting the college by electricity were submitted. Twenty-six contracts were tabled, and, without going into them, the committee handed the offers to the convener and Mr. Murray, electrical engineer, with a request that they should schedule them, so that they might be considered at a future meeting. A discussion has taken place in the Town Council as to whether, in addition to electric light fittings, gas-pipes should be inserted in the new police buildings. Mr. Young and others argued that such a proposal was unnecessary, and showed want of confidence in the electric light. Bailie M'Kenzie stated that the proposal was made on the advice of Mr. Ruthven Murray, but he agreed that the committee should reconsider the matter. At a meeting of the Gas Committee of the Council on Tuesday, it was resolved to recommend that the price to be charged for lighting the streets by electricity should be 3¾d. per lamp per hour, and that the Street Department have the entire control of the lamps, except in the case of a sudden breakdown. A question was put to Mr. Murray, electrical engineer, with reference to a statement made at Monday's meeting of the Council to the effect that he had said that gas-pipes would be required to be laid in the new police buildings, which it had been resolved to illuminate with electricity. Mr. Murray said that he had been misunderstood with regard to the matter, and that he never did, and never would, advise gas fittings and pipes to be introduced into a building into which the electric light was to be put. The object of the question was to prevent a statement going out which would mislead anyone intending to adopt the electric light to think that gas would be necessary.

Lighting of the Embankment.—At last Tuesday's meeting of the London County Council, the Works Committee reported that in accordance with the reference from the Council they had considered the estimate and specification submitted by the Highways Committee for the erection of a generating station for the electric lighting of the Victoria-embankment and the Westminster and Waterloo Bridges. They reported in accordance with standing orders that they were not satisfied with the estimate, and recommended that the estimate be referred back to the Highways Committee. With respect to the same station the Highways Committee at the same meeting reported: "The Council on June 5 resolved that the generating station for the electric lighting of the Victoria-embankment and the Westminster and Waterloo Bridges should be constructed without the intervention of a contractor; and the plans, specification, and estimate were referred to the Works Committee for that purpose, with an instruction that the work should be carried out with all possible expedition. We have received an intimation from that committee of its intention to report to the Council on Tuesday next that the estimate is not sufficient; but, having again given very careful consideration to the estimate, we are of opinion that the amount

Digitized by Google

is adequate, and we should therefore not be justified in increasing it. In the circumstances we think the best course would be to submit the work for public competition; and we recommend that the resolution of the Council of June 5, 1894, which directs that the generating station for the electric lighting of the Victoria-embankment and the Waterloo and Westminster Bridges shall be constructed without the intervention of a contractor, be rescinded, and that tenders for the execution of the work be invited by public advertisement."

Fareham.—At a meeting of the Fareham Local Board it was determined by the casting vote of the chairman that an offer should be made to the electric light company to purchase the undertaking for £5,000, an additional £1,000 being allowed for laying the wires underground. The following are the details of the agreement: The sum of £5,000 to include the buildings (on land held on lease), together with all the plant, machinery, mains, meters, and all other electrical and mechanical appliances appertaining thereto, as entered in and shown by the books of the company, together with the benefit of their provisional order. The Browett-Lindley compound vertical engine not to be included in the above-mentioned sum of £5,000, but to be for the credit of the company to provide another engine as herewith mentioned. The company further undertake to execute the following works for the additional sum of £1,000: (1) To lay underground (as provided for by section 82 of the provisional order) the electric lines in the streets and parts of streets as follows: Gosport-road from the electric light depôt to the junction with South-street (Quay-street), South-street, West-street from a point opposite Trinity Church to the junction with High-street, and High-street from its junction with West-street to Wallington Hill. (2) To provide a new engine of equal capacity to the horizontal compound engine by Ransomes, Sims, and Jefferies, now in use. The company also agree that, provided the above works be carried out for a less sum than the before-mentioned sum of £1,000, the Fareham Local Board shall receive credit for any such sum; on the other hand, any excess over and above £1,000 shall be paid by the company. It was arranged that, pending the application to the Local Government Board for permission to borrow the necessary loan, the clerk should see to the preparation of the contract for the purchase of the electric works, and that it should be considered either at a special meeting or at the next ordinary meeting of the Board.

Newcastle.—Messrs. Bainbridge and Co., of Market-street and Bigg Market, Newcastle, are making some very extensive alterations, and considerably extending their premises, which necessitates a complete rearrangement of their motive power plant, and many additions thereto. This has been placed in the hands of Messrs. Thos. Beecroft and Co., engineers, Leeds, and the contracts for the work comprise one Lancashire boiler 20ft. by 7ft., to supply the steam to a new horizontal engine fitted with patent automatic triple-expansion gear, and giving off 75 effective horse-power. This boiler also supplies the steam for heating the premises. There is also a compound Robey engine and boiler of 125 effective horse-power, which is used for electric lighting exclusively. The engines, boilers, etc., are being made by Messrs. Robey and Co., Limited, Lincoln. The whole of the electrical work is being carried out by Messrs. Ernest Scott and Mountain, Limited, Close Works, Newcastle, on a most extensive and elaborate scale. This portion of the work includes one of their latest dynamos, capable of running 1,000 16-c.p. lamps. There is also another dynamo for running 300 16-c.p. lamps, electric motors, etc. These are for day service, and are driven by the 75-h.p. engine. When completed the whole will form one of the largest electric light installations in the North of England. Messrs. Armstrong and Knowles, of Newcastle, are the architects, to whose plans the whole of these alterations are being carried out. Messrs. Scott and Mountain have also a considerable amount of pumping work, etc., in hand. For Messrs. G. B. and T. E. Forster, mining engineers, Newcastle, they are finishing a complete set of electric pumping plant, consisting of Corliss engine, 60-unit dynamo, and seven sets of pumping machinery, to take the place of the existing wire-rope pumps. For Messrs. Straker and Love, Brancepeth Colliery, County Durham, a set of pumping machinery, to deliver 300 gallons of water per minute against a head of 420ft., with engines, etc.

Birkenhead.—An enquiry was held on Tuesday at the Town Hall by Mr. Rienzi Walton, M.I.C.E., one of the Local Government Board inspectors, into an application by the Birkenhead Corporation to borrow £35,000, of which £20,000 is for electric lighting. The Town Clerk, Mr. A. Gill, represented the Corporation, and said the loan of £20,000 for electric lighting was made up of two different items. The first was £1,576 in respect of 3,152½ yards of land in Bentinck-street for a site for the central generating station. The Corporation had entered into a provisional agreement to purchase the land, which was really the only suitable site in the borough. The second item was £18,424 for the erection of works, and in respect of this the inspector might possibly withhold his certificate, because at the present moment the Corporation had not really approved of the plans prepared by Mr. Shoolbred. The site which they had secured was more than sufficient for the scheme proposed for the present, but was not too large for the full carrying out of the electric lighting order. Alderman Deakin said that the price of the land was 10s. per yard, which was very moderate. The gentleman who owned the land, knowing the purpose for which the Corporation required it, had come forward with great public spirit and sold it at a considerable sacrifice to himself. The Town Clerk said, in regard to the erection of works, that Mr. Shoolbred had submitted an alternative plan, showing a greatly improved building at an extra cost of £2,000, but the Finance Committee did not see their way to approve it. The Corporation were not in a position to submit the details, but they were practically agreed that they would have to build a boiler-house, workshops, chimney, etc. The inspector said he would proceed with the enquiry as usual, and would hold over his report until he got a subsequent notification from the Corporation. If they then approved of the plans, his report would hold good, and if not it must be left to the Local Government Board. Mr. Shoolbred then gave detailed evidence of the scheme.

A Police Court Case.—At Bow-street Police Court on Wednesday Mr. Lawrence Henry Bloomfield, electrician, of Queen Victoria-street and Richmond, appeared to a summons charging him with obtaining by false pretences £120 from Richard Lonsdale. Mr. Purcell appeared for the complainant, and Mr. Travers Humphreys for the defendant. Mr. Purcell said that he wished to withdraw the summons. The facts of the case did not warrant all that was set forth in the information, and there was reason to believe that there had been no intention to defraud. Mr. Vaughan said that, according to the information, there was a *primâ facie* case, and the matter must be explained. Mr. Humphreys said that, according to the information, the complainant was told by the defendant that he had secured a contract with the Brighton and Hove Electric Light and Supply Company. The complainant contended that the defendant had not secured such a contract. As a matter of fact, the defendant had not secured it; but he was in communication with a man named Stevens who promised to secure it for him. The defendant borrowed money from the complainant for the purpose of buying electric lamps in Germany, and, as a matter of fact, he went to Germany and made purchases there. Mr. Vaughan said that the complainant had better give evidence, and then Stevens ought to be called. The complainant stated that he was an electrical engineer carrying on business in the Strand. Last year the defendant said he was an agent for a Dutch firm of electric lamp makers, and the complainant agreed to supply him with money for the purchase of lamps. In February last the defendant said that he had secured a contract with the Brighton and Hove Electric Lighting Company. Limited. Believing this to be true, the complainant advanced him £120 to enable him to go abroad and purchase lamps. In reply to the magistrate, the complainant said that the defendant told him he had secured the contract through another man, although he made no mention of that in the information. Mr. Vaughan said that in the face of that admission it would be useless to proceed further. The other man referred to might have made a false statement to the defendant as to the Brighton and Hove contract. There appeared to be no intention to defraud, and the case would be dismissed.

Salisbury.—Another important step has been taken towards the supply of electricity in Salisbury by a public company. When the consent of the Town Council to the application for a license was sought last month by Mr. W. H. Gramshaw, it was pointed out by that gentleman that, to prevent the enterprise being delayed, it was necessary that the sanction of the Salisbury Corporation should be obtained and notice given of application to the Board of Trade before July 1. After twice considering the matter at special meetings, the Town Council unanimously consented to Mr. Gramshaw's request; and notice has been given of an application to the Board of Trade, under the Electric Lighting Acts, for a license to enable the Salisbury Electric Light and Supply Company, Limited, to produce and supply electricity for public and private purposes within the city. The streets and parts of streets comprising the area within which the company propose to lay electric mains are: Fisherton street from the railway bridge eastwards, Bridge-street, Silver-street, Butcher-row, High-street, Minster-street, Blue Boar-row, Castle-street from Blue Boar-row to Chipper-land, Endless-street from Blue Boar-row to Chipper-lane north side, Winchester-street from Blue Boar-row to the east corner of Rollestone-street, Milford-street from Catharine-street to the corner of Brown-street, the Canal, New-street, Catharine-street, Brown-street from the corner of Winchester-street to the corner of Milford-street, the Close within the Close wall, St. Ann's-street as far as the borough boundary on the Southampton-road, St. John-street, and Queen-street. The above streets form the compulsory area, but outside this there is, as Mr. Gramshaw explained to the Town Council last month, a voluntary area comprising the remainder of the municipal borough. Within the compulsory area the company must lay distributing mains within one year after the acquisition of the license, but as regards the voluntary area, it is at their discretion to extend their supply to any part of it or not, and of course the extension would depend upon the opinion formed by the company whether a supply was likely to prove remunerative or not. Mr. Alex. J. Murray, 1, Clement's-inn, London; Messrs. Macdonald and Malden, Salisbury; and Sherwood and Co., Great George-street, Westminster, are the solicitors.

Dublin.—Particulars have been obtained from Mr. Spencer Harty, C.E., city engineer and surveyor, Dublin, by the *Western Mail* as to the experiences of the Corporation in connection with the introduction of the electric light. Mr. Harty says: "In reply to your enquiry as to our experience of electric lighting, I have to say that the installation by this Corporation has been most successful. The price paid for gas in Dublin is 3s. 7d. per 1,000 cubic feet, and the charge for electric light is 7d. per Board of Trade unit (less 7½ per cent. on quarterly accounts over £100, and 5 per cent. under £100, if paid within two months). These figures will give you an idea of the relative cost, but it must be borne in mind that the action of gas on interior decorations of houses, libraries, fine goods in warehouses, etc., is very detrimental, and these considerations must be taken into account in estimating the relative cost

Digitized by Google

of the two lights. It certainly would be unfair to the electric light system to ignore its advantages in this respect, and to take the figures of the cost in the abstract, for purposes of comparison. I am satisfied that hotels, clubs, theatres, and such buildings, containing costly decorations, as well as for warehouses stored with fine goods, the electric light will be found of greater advantage. On the question of profits, our working for the first year, ending December 31 last, shows a surplus of £1,545, which would represent a dividend of about 4½ per cent. per annum on the amount of capital remaining due at the close of the year. I cannot say to what extent the consumption of gas has been affected by the electric light, as the gas undertaking is not controlled by the Corporation. The number of incandescent lamps on the electric light installation is equivalent to 14,000 8-c.p. lamps, and we have 81 arc lamps in the thoroughfares. I send you a copy of a pamphlet descriptive of the works, which was published soon after the introduction of the light. Since then, however, we have introduced plant for day-load lighting, and in response to pressing applications for the light are now engaged on a further extension of the works." The Dublin pamphlet enables customers to estimate the cost. Thus a lamp of 16 c.p. consumes 65 watts and a lamp of 8 c.p. 40 watts per hour. If there be installed in a house 30 lamps of 8 c.p., and the average number of hours in the year during which those lamps are burnt is 500, the average consumption of units would be as follows: Thirty lamps, each of 40 watts—1,200. One thousand two hundred watts multiplied by 500 hours give a result of 600,000 watt-hours, or 600 units. Up to 30 units the Dublin Corporation at present charge £1 per quarter; over 30 and up to 60 units, £2; over 60 units, 7d. per unit.

Edinburgh.—The question of the electric lighting of George-street and neighbouring thoroughfares has again been under the consideration of the Lord Provost's Committee of the Edinburgh Town Council, when a report from the engineers on the subject was directed to be referred to the Cleaning and Lighting Committee. On Monday last the Lord Provost laid the foundation-stone of the central electric light station in Torphichen-street. The installation which is in progress is the first for the supply of electric light for private purposes in Edinburgh, but 13 years ago there was an abortive experiment in public lighting. In June, 1881, the Town Council accepted an offer of the Anglo-American Brush Electric Corporation to light Princes-street, the North Bridge, and Waverley Bridge, for three months, at a cost of £389, with power to the Council to purchase the plant, at the end of the trial, for £2,407. The experiment did not give satisfaction, and at the end of the three months the plant was cleared away in December, 1881, the whole thing having cost the town £838. The Brush Corporation made application again in June, 1888, for permission to lay down mains in Rose-street-lane for the purpose of supplying electricity in Princes-street; but although the application was favourably reported upon, it was not given effect to. In 1889 six companies gave notice of their intention to apply for provisional orders, but the Town Council announced their intention of taking up the matter themselves, and in 1891 they obtained a provisional order. Prof. Kennedy was appointed consulting engineer, and he submitted a scheme. The station will have a frontage to Torphichen-street of 200ft., and to Dewar-place of about 150ft. It is built to accommodate about 17 boilers—equivalent to 6,000 h.p.—and about a score of engines and dynamos; but until the demand requires it, it is not proposed to put down more than six boilers and six engines and dynamos, which will be sufficient to supply an equivalent of 40,000 lamps of 8 c.p. Councillor Mackenzie, at the laying of the foundation-stone on Monday, said that it was proposed to light the compulsory area and a good portion of the New Town beyond that area, and plant would be put down in the central station sufficient to do so. They were, however, making provision in this central station for doing a great deal more than that, because, judging from what was taking place in other towns, there would soon be a much greater demand for the electric light than they could supply with the plant they were providing at present. They had, therefore, made the station large enough to meet practically the wants of the whole town, though it was not intended to supply the whole of Edinburgh by one system. There was considerable difference of opinion as to the merits of the high-tension and low-tension systems, and on the advice of Prof. Kennedy they were to light the central parts of the city with the low-tension system, and the districts with the high-tension. They hoped that before the end of the year they would be in a position to turn on the current. The Lord Provost, who also spoke, said that they were now within sight of the time when they should be able to give the electric light to every person who wished to pay for it. He desired to impart this piece of elementary information to them, for he found that the scheme was not well understood—that the primary purpose of the order was to supply the electric light to houses. The lighting of the streets with the electric light was a mere incident of the scheme. One effect of proceeding leisurely with the scheme was this, that they were able to tell the ratepayers how much the lighting of the streets would cost, so that they would be saved making a wry face when the bill came in. He did not think that gas was played out. He believed they would both be good servants—gas and electricity—in their own ways; for in the future he hoped to see gas used a great deal more for cooking and for motors. Hitherto their Edinburgh gas had been too expensive to make free use of it in such a way. Until lately their standard gas had been of 27 c.p. or 28 c.p., whereas in London it varied from 14 c.p. to 16 c.p. If they diminished the illuminating power they could supply it at a price which would induce people to use it for the purposes he had indicated, and those people who wanted a high light could go in to use the electric light. They were starting with a low price in Edinburgh for the electric light. They could charge 8d. per unit, but they were only to charge 6d., and those people who used large quantities would get it for 4½d. It was the interest of everyone who used the electric light to get others to do the same, because when their 6,000 h p. was in use they would likely be able to supply the light for a little over 4d. a unit. A dinner subsequently took place in the Council Chambers, and later in the evening Prof. Kennedy delivered a public lecture on the subject of the electric light in Edinburgh. He pointed out that the highest charge for current would be 6d. per Board of Trade unit. The lamps would cost 1s. 3d. each. In these circumstances the cost would be about a seventh of a penny per hour for an 8-c.p. lamp, and a farthing per hour for a 16-c.p. lamp. Each incandescent lamp would last 500 or 600 hours, giving effective light, so that in a private house, with gas at the present price, electric light ought not to cost more than gas. On Tuesday night Principal Grant Ogilvie made arrangements by which for an hour the fully-equipped electrical appliances at the Heriot-Watt College were thrown open to the public, with the view of giving those who cared to avail themselves of it an opportunity of seeing the method of applying electricity to illuminating purposes. The engines and dynamos used in the lighting of the college buildings were on view, as also were the electrical laboratories of the institution.

Electric Lighting of Hampstead.—In our issue of 15th inst. we recorded in our "Business Notes" the report of the Finance Committee of the London County Council, given on the 12th inst., on the subject of the loan to the Hampstead Vestry. At Tuesday's meeting the Finance Committee reported: "On the 12th inst. we reported on the application of the Vestry of Hampstead for sanction to the borrowing of a further sum of £25,000 on the instalment system, for electric lighting purposes, for 50 years, and recommended the Council to sanction the Vestry borrowing £23,500, to be repaid in 25 years Consequent, however, on the receipt of a letter from the Vestry on that day, asking that the matter might be further considered, the report was withdrawn from the Council. The Vestry state in their letter that they have entered into contracts in connection with this work for £20,080, and estimate the cost of further works at £1,425, making together £21,505. The details of these figures were given in the report, in which it was stated that the value placed on the works by the Council's engineer was £19,647. It has since been found that a clerical error was made in these figures by the omission of £848, which added to the £19,647 amounts to £20,495, and adding also £8,900, the value of the central supply station, chimney shaft, and offices as mentioned in the last report, there is produced a total of £29,395, and deducting the sum of £5,000 already advanced the sum of £24,395, or, say, £24,400, remains to be borrowed. The Hampstead Vestry urge that as the Council gave its sanction to the repayment by the Vestry of St. Pancras of the proposed loans of £60,000 and £15,400 in 42 years, they should be allowed the same period to repay their loan. The Council must, however, be reminded that these loans were sanctioned in December, 1891, and in July, 1893, before the Council was in full possession of the views of the Treasury upon this subject, and before the question of a depreciation fund for renewals had been considered in connection with these electric lighting schemes. The subject of the term to be allowed for electric lighting loans was fully reported upon to the Council on February 13, 1894, and considered, with the result that the sanction to the raising of the £15,400 by the St. Pancras Vestry, repayable in 42 years, was withdrawn, and consent given to the raising of £29,700 (inclusive of the £15,400) to be repaid in 25 years, and this period was passed by the Treasury in anticipation of the Vestry taking up the loan. The Vestry also state that they are in a better position than St. Pancras, inasmuch as they are erecting the works on their own freehold ground, whilst St. Pancras borrowed £10,000 to acquire a site for that purpose. It may, however, be mentioned that the Hampstead Vestry borrowed from the late Board in 1880 the sum of £4,000 to purchase two acres of land in the Finchley-road for the purposes of a stone and store yard, repayable in 49½ years—*i.e.*, by October 1, 1929—upon part of which land they now intend to erect their electric lighting works: there is consequently an outstanding charge on the site for 36 years yet to come. The main reasons adduced by the committee in recommending the term of 25 years on the last occasion were: (1) That in an undertaking of this kind a very large proportion of the initial cost is for short-lived purposes, and in this respect it differs from a street improvement and many other works. It may be mentioned that the Council has decided that the initial cost of its own installation of electric light on the Victoria-embankment should be repaid in 25 years. (2) That from the nature of the undertaking large sums must be expended for renewals of boilers, dynamos, mains, etc., at given periods in addition to ordinary maintenance repairs and small renewals, and that it would be practically impossible for the Vestry to pay these large sums out of the income of the year. The Vestry would be urged by the ratepayers of the day to apply for a loan to meet such heavy expenditure, and the Council would find it difficult to refuse its sanction. The Vestry do not apparently propose to establish a depreciation fund to meet these renewals, as an electric lighting company would do, and even if the Vestry did create such a fund the Council would have no power to see that it was kept up to a proper level. (3) That the term of 25 years being but slightly in excess of the equated period of the life of the work, will leave the Council and the Vestry a perfectly free hand as regards future borrowings which may become necessary to meet recurring expenditure for renewals, improved methods of generation or supply involving a large outlay, which it would be unreasonable to charge on the current rates.

Digitized by Google

(4) That the term of 25 years is the one sanctioned by the Local Government Board for electric lighting loans—*i.e.*, for a complete installation, including the purchase of land in some cases. That many of the large corporations—such as Manchester, Bristol, Blackburn, Portsmouth, and Leicester—have borrowed on these terms, and are content to carry out their electric lighting schemes under these conditions, whilst the Council in addition gives, in the case of loans for sites, the longest period (50 to 60 years) for repayment. The Vestry contend that they should be allowed a longer period than one based on the life of the work, in order that they may be able to successfully compete with a company which does not have to pay off its capital; but even if this argument be admitted, it must be remembered that a company cannot raise its capital at 3½ per cent. as the Vestry can, and that a company has to establish a reserve fund to meet depreciation and other contingencies, so that the Vestry is not apparently placed at any disadvantage as compared with a company. We see no reason why the Council should go back from its decision of February 13 last as regards the term to be allowed for these electric lighting loans. The equated period in the case of Hampstead works out at 22 years, and the term of 25 years appears to us to be a fair one to allow. We therefore repeat our former recommendation, amended so as to cover the amount inadvertently omitted: '(*a*) That the sanction of the Council be given to the borrowing by the Vestry of Hampstead of the sum of £24,000 towards defraying the cost of an electric light installation in that parish, at a rate of interest not exceeding £3. 10s. per cent. per annum, and to be repaid by instalments of principal, or principal and interest combined, within a period of 25 years from the date of the loan; (*b*) that the seal of the Council be affixed to the order submitted with the report.'" In the discussion on the report of the Finance Committee, Mr. Benn, M.P., and others urged that the Council should give the vestries the advantage of the provisions of the Money Act of last year, which provided that the term might be 42 years. Mr. H. Harben moved an amendment to this effect, and it was carried by a large majority.

PROVISIONAL PATENTS, 1894.

JUNE 18.

11733. **Improvements in or appertaining to electrical railways or tramways.** Rudolf Altschul, 6, Lord-street, Liverpool.

11780. **Improvements in the means of distributing alternating electricity.** David Cook, 30, Lancaster-park, Richmond, Surrey.

JUNE 19.

11809. **Electrical life-preserving fire-alarm.** John Brafield Rolfe, 26, Burnt Ash-road, Lee, London.

11813. **Improvements in phonographs.** Frederick Woilliard-Rigg and Harry Ernest Scarborough, Wade-street, Halifax.

11814. **Automatic auxiliary electric block, and engine distance caution signal for railways.** William George Martin, Woodside Park Station, G.N.R., London.

11822. **A new attachment for hanging electroliers and other electric fittings.** Augustus Marsden, 18, Gironde-road, Walham Green, London.

11840. **An instrument for finding the direction of induced current, rotation, or magnetisation in an electric generator or motor.** John Willoughby Meares, Queen-street, Chelmsford.

11843. **To illuminate by electricity castings of flowers, fruits, and foliage taken from nature for the purpose of decoration in plaster either cornices, centre ornaments, entablature, etc.** Charles Gillard, High-street, Chard, Somerset.

JUNE 20.

11903. **Improvements on conduit electric systems for supply of current to tramway, rail, or other motors.** Arthur Alexander Govan, 15, Renfield-street, Glasgow.

JUNE 21.

11979. **Improvements in or relating to metal brushes for dynamos.** Wilhelm von Braucke, 16, Finkle-street, Stockton-on-Tees.

11995. **Improvements in testing and working electric telegraphs.** William Thomson (Baron Kelvin), 154, St. Vincent-street, Glasgow.

12006. **Improvements in iron clips for fixing electric light casing and other purposes.** Charles Bishop, 66, Byles-street, Toxteth Park, Liverpool.

12009. **An automatic electrical switch.** Wilfred Robert Vernet Marshall, Torrieburn, Barnes, London.

12045. **Improvements in secondary batteries.** Alexander Schanschieff, 191, Fleet-street, London.

JUNE 22.

12099. **Improvements in the construction of armatures for dynamo-electric machines and electric motors.** Henry Francis Joel, 44, Lavender-grove, Dalston, London. (Complete specification.)

12100. **Improvements in or connected with signalling electrically to locomotives or trains in motion.** John William Sunderland and George Bilbrough, 33, Chancery-lane, London.

12131. **Improvements in electric brake operating mechanism for vehicles.** Louis Eugene Freedley, 45, Southampton-buildings, Chancery-lane, London. (Dated applied for under Patents, etc., Act, 1883, sec. 103, December 29, 1893, being date of application in United States.) (Complete specification.)

12137. **Improvements connected with a combined walking-stick and electric lamp appliances.** Harry Newbold, 166, Fleet-street, London. (Complete specification.)

JUNE 23.

12140. **Improvements in electric igniters.** Alan Archibald Campbell Swinton, 66, Victoria-street, Westminster.

12147. **An improved electrical gripper bar, applicable to printing machines.** William Brewer Silverlock, 18, Fulham-place, Paddington, London.

12181. **Improvements in electrically-heated apparatus for use in soldering, brazing, and like operations.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

12183. **Underground electrical propulsion.** John Edward Parker, 1, Broad-street, New York, U.S.A.

12221. **Improvements connected with electrical furnaces.** Philip Middleton Justice, 55, Chancery-lane, London. (Edward Goodrich Acheson, United States.)

SPECIFICATIONS PUBLISHED.

1891.

3664. **Electrical switches.** Binswanger. (Second edition.)

1893.

10597. **Adapting electric lamps to candle fittings, etc.** Sluce.

10772. **Ceiling roses, etc., for electric connections.** Cutting.

12785. **Electric switches.** New and Mayne.

13749. **Electric elevators.** Smith.

14271. **Distributing electricity.** Bertram and Hope-Johnstone.

14533. **Supplying electrical energy to motor vehicles on electric railways, etc.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

14715. **Electric bell pulls and pushes.** Harcourt.

15510. **Electric arc lamps.** Brookie.

16026. **Regulator for dynamo-electric machines.** Siemens Bros. and Co., Limited, and Holmes.

1894.

3072. **Arc lamps.** Woolverton.

8587. **Electric railways.** Lake. (Purvis and another.)
